Attempts to find genetic markers that are associated with hypertension have been largely unsuccessful. The detailed mechanism of heredity, i.e., how many genes and loci are involved and their mode of inheritance have not yet been conclusively elucidated.

(d) ETHNICITY: Population studies have consistently revealed higher blood pressure levels in black communities than other ethnic groups (1). Average difference in blood pressure between the two groups vary from slightly less than 5 mm Hg during the second decade of life to nearly 20 mm Hg during the sixth. Black Americans of African origin have been demonstrated to have higher blood pressure levels than whites.

2. Modifiable risk factors

(a) OBESITY: Epidemiological observations have identified obesity as a risk factor for hypertension (14). The greater the weight gain, the greater the risk of high blood pressure. Data also indicate that when people with high blood pressure lose weight, their blood pressure generally decreases. "Central obesity" indicated by an increased waist to hip ratio, has been positively correlated with high blood pressure in several populations.

(b) SALT INTAKE: There is an increasing body of evidence to the effect that a high salt intake (i.e., 7-8 g per day) increases blood pressure proportionately. Low sodium intake has been found to lower tbe blood pressure (15). For instance, the higher incidence of hypertension is found in Japan where sodium intake is above 400 mmol/day while primitive societies ingesting less than 60 mmol/day have virtually no hypertension (16). It has been postulated that essential hypertenives have a genetic abnormality of the kidney which makes salt excretion difficult except at raised levels of arterial pressure (5).

Besides sodium, there are other mineral elements such as potassium which are determinants of blood pressure. Potassium antagonizes the biological effects of sodium, and thereby reduces blood pressure. Potassium supplements have been found to lower blood pressure of mild to moderate hypertensives. Other cations such as calcium, cadmium and magnesium have also been suggested as of importance in reducing blood pressure levels.

(c) SATURATED FAT: The evidences suggest that saturated fat raises blood pressure as well as serum cholesterol (17). For further details refer to chapter 10.

(d) DIETARY FIBRE: Several studies indicate that the risk of CAD and hypertension is inversely related to the consumption of dietary fibre. Most fibres reduce plasma total and LDL cholesterol (1).

(e) ALCOHOL: High alcohol intake is associated with an increased risk of high blood pressure. It appears that alcohol consumption raises systolic pressure more than the diastolic. But the finding that blood pressure of normal and normal to abstinent patients suggest that alcohol-induced elevations may not be fixed, and do not necessarily lead to sustained blood pressure elevation (5).

(f) HEART RATE: When groups of normotensive and untreated hypertensive subjects, matched for age and sex, are compared, the heart rate of the hypertensive group is invariably higher. This may reflect a rewiring of sympathetic activity at a higher level. The role of heart variability in blood pressure needs further research to elucidate whether the relation is causal or prognostic (1).

(g) PHYSICAL ACTIVITY: Physical activity by reducing body weight may have an indirect effect on blood pressure.

(h) ENVIRONMENTAL STRESS: The term hypertension itself implies a disorder initiated by tension or stress. Since stress is nowhere defined, the hypothesis is untenable (3). However, it is an accepted fact that psychosocial factors influence through mental processes, consciously or unconsciously, to produce hypertension. Virtually all studies on blood pressure and catecholamine levels in young people revealed significantly higher norepinephrine levels in hypertensives than in normotensives. This supports the contention that over-activity of the sympathetic nervous system has an important part to play in the pathogenesis of hypertension (11). The WHO recommends the following approaches in the prevention of hypertension:

1. Primary prevention
   (a) Population strategy
   (b) High-risk strategy

2. Secondary prevention

1. PRIMARY PREVENTION

Although control of hypertension can be successfully achieved by medication (secondary prevention) the ultimate goal in general is primary prevention. Primary prevention has been defined as "all measures to reduce the incidence of disease in a population by reducing the risk of onset" (19). The earlier the prevention starts the more likely it is to be effective.

In connection with primary prevention, terms such as "population strategy" and "high-risk strategy" have become established (5, 20). The WHO has recommended these approaches in the prevention of hypertension. Both the approaches are complementary.

a. POPULATION STRATEGY

The population approach is directed at the whole population, irrespective of individual risk level. The concept of population approach is based on the 'act that even a small reduction in the average blood pressure of a population would produce a large reduction in the incidence of cardiovascular complications such as stroke and CHD (18). The goal of the population approach is to shift
the community distribution of blood pressure towards lower levels or “biological normality” (17). This involves a multifactorial approach, based on the following non-pharmacotherapeutic interventions:

(a) NUTRITION: Dietary changes are of paramount importance. These comprise: (i) reduction of salt intake to an average of not more than 5 g per day (ii) moderate fat intake (iii) the avoidance of a high alcohol intake, and (iv) restriction of energy intake appropriate to body needs.

(b) WEIGHT REDUCTION: The prevention and correction of over weight/obesity (Body Mass Index greater than 25) is a prudent way of reducing the risk of hypertension and indirectly CHD; it goes with dietary changes. (c) EXERCISE PROMOTION: The evidence that regular physical activity leads to a fall in body weight, blood lipids and blood pressure goes to suggest that regular physical activity should be encouraged as part of the strategy for risk-factor control (25).

(d) BEHAVIOURAL CHANGES: Reduction of stress and smoking, modification of personal lifestyle, yoga and transcendental meditation could be profitable. (e) HEALTH EDUCATION: The general public acquire preventive advice on all risk factors and related health behaviour. The whole community must be mobilized and made aware of the possibility of primary prevention, and (f) SELF-CARE: An important element in community-based health programmes is patient participation. The patient is taught self-care, i.e., to take his own blood pressure and keep a log-book of his readings. By doing so, the burden on the official health services would be considerably reduced. Log-books can also be useful for statistical purposes and for the long-term follow-up of cases (22).

Table 2 shows some of the lifestyle modifications to manage hypertension.

b. HIGH RISK STRATEGY

This is also part of primary prevention. The aim of this approach is "to prevent the attainment of levels of blood pressure at which the institution of treatment would be considered" (3). This approach is appropriate if the risk factors occur with very low prevalence in the community (3).

Detected of high-risk subjects should be encouraged by the optimum use of clinical methods. Since hypertension tends to cluster in families, the family history of hypertension and "tracking" of blood pressure from childhood may be used to identify individuals at risk.

2. SECONDARY PREVENTION

The goal of secondary prevention is to detect and control high blood pressure in affected individuals. Modern anti-hypertensive drug therapy can effectively reduce high blood pressure and consequently, the excess risk of morbidity and mortality from coronary, cerebrovascular and kidney disease. The control measures comprise:

(i) EARLY CASE DETECTION: Early detection is a major problem. This is because high blood pressure rarely causes symptoms until organic damage has already occurred, and our aim should be to control it before this happens. The only effective method of diagnosis of hypertension is to screen the population. But screening, that is not linked to follow-up and sustained care, is a fruitless exercise. It is emphasized that screening should not be twisted if health resources for treatment and follow-up are not adequate.

In the developed countries, mass screening is not considered essential for the adequate control of blood pressure in the population. In Europe, the large majority of people have at least one contact in every 2 year with the health service. If blood pressure is measured at each such contact, the bulk of the problem of detecting those in need of intervention is solved.

(ii) TREATMENT: In essential hypertension, as in diabetes, we cannot treat the cause, because we do not know what it is. Instead, we try to scale down the high blood pressure to acceptable levels. The aim of treatment should be to obtain a blood pressure below 140/90, and ideally a blood pressure of 120/80. Control of hypertension has been shown to reduce the incidence of stroke and other complications. This is a major reason for identifying and treating asymptomatic hypertension. Care of hypertensives should also involve attention to other risk factors such as smoking and elevated blood cholesterol levels (18).

<td>Recommendation</td>
</tr>
<tr>
<td>Weight reduction</td>
<td>Maintain normal body weight (BMI, 18.5-24.9)</td>
</tr>
<tr>
<td>Adopt DASH eating plan</td>
<td>Consume a diet rich in fruits, vegetables and low-fat dairy products with a reduced content of saturated fat and total fat</td>
</tr>
<tr>
<td>Dietary sodium reduction</td>
<td>Reduce dietary sodium intake to no more than 100 mEq/d</td>
</tr>
<tr>
<td>Physical activity</td>
<td>Engage in regular aerobic physical activity such as brisk walking (at least 30 minutes per day, most days of the week)</td>
</tr>
<tr>
<td>Reduction of alcohol consumption</td>
<td>Limit consumption to no more than two drinks per day (1 oz or 30 ml ethanol, eg, 24 oz beer, 10 oz wine, or 3 oz 80-proof whiskey) in most men, and no more than one drink per day in women and lighter-weight persons</td>
</tr>
</tbody>
</table>

For overall cardiovascular risk reduction, stop smoking.

The effects of implementing these modifications are dose and time dependent and could be higher for some individuals.

BMI - body mass index calculated as weight in kilograms divided by the square of height in metres;

DASH - Dietary Approaches to Stop Hypertension.

Source: (3)
(iii) PATIENT COMPLIANCE: The treatment of high blood pressure must normally, be life-long and this presents problems of patient compliance, which is defined as "the extent to which patient behaviour (in terms of taking medicines, following diets or executing other lifestyle changes) coincides with clinical prescription". The compliance rate can be improved through education directed to patients, families and the community.

Intensive research carried out during the past decade, aiming at control of hypertension at the community level, has already provided valuable results. The studies have shown that control of hypertension in a population is feasible, that it can be carried out through the existing system of health services in different countries, and that the control of blood pressure leads to a reduction of complications of high blood pressure – namely stroke, heart failure and renal failure. In some of the projects the incidence of myocardial infarction was also reduced. As a result of these findings some countries have launched nationwide control programmes in the field of hypertension (23).

References

STROKE

The term "stroke" (gym: apoplexy) is applied to acute severe manifestations of cerebrovascular disease. It causes both physical and mental crippling. WHO defined stroke as "rapidly developed clinical signs of focal disturbance of cerebral, spinal cord, retinal, or peripheral nerves lasting more than 24 hours or leading to death, with no apparent cause other than vascular origin" (1). The 24 hours threshold in the definition excludes transient ischaemic attack (TIA) which is defined to last less than 24 hours, and patients with stroke symptoms caused by subarachnoid haemorrhage, tumours, poisoning or trauma are excluded.

The disturbance of cerebral function is caused by three morphological abnormalities, i.e., stenosis, occlusion or rupture of the arteries. Dysfunction of the brain ("neurological deficit") manifests itself by various neurological signs and symptoms that are related to extent and site of the area involved and to the underlying causes. These include coma, hemiplegia, paraplegia, monoplegia, multiple paralysis, speech disturbances, nerve paresis, sensory impairment, etc. Of these hemiplegia constitutes the main somato-neurological disorder in about 90 per cent of patients (2).

Stroke includes a number of syndromes with differing aetiologies, epidemiology, prognosis and treatment. These are listed below:

A. Ischaemic stroke
   a. Lacunar infarct
   b. Carotid circulation obstruction
B. Haemorrhagic stroke
   a. Spontaneous intracerebral haemorrhage
   b. Subarachnoid haemorrhage
   c. Intracranial aneurysm
   d. Arteriovenous malformations

Problem

Stroke is a worldwide health problem. It makes an important contribution to morbidity, mortality and disability in developed as well as developing countries. Although there are substantial differences in frequency from place to place, cerebral thrombosis is usually the most frequent form of stroke encountered in clinical studies, followed by haemorrhage. Subarachnoid haemorrhage and cerebral embolism come next as regards both mortality and morbidity (2). Hemorrhagic stroke (spontaneous intracerebral haemorrhage) is more common in Japan than elsewhere (1).

MORBIDITY AND MORTALITY

Cerebrovascular disease remains a leading cause of death from NCDs. In 2008 it was estimated that cerebrovascular disease accounted for 6.1 million deaths worldwide, equivalent to 10.8 per cent of all deaths. Majority of these deaths occurred in people living in developing countries and 33.72 per cent of the subjects were aged less than 70 years (3). Additionally, cerebrovascular disease is the leading cause of disability in adults and each year millions of stroke survivors have to adopt life with restriction in activities of daily living as a consequence of stroke. Many surviving stroke patients will often depend on other people's continuous support to live (4).

In demographically developed countries, the average age at which stroke occurs is around 73 years reflecting the older age structure of these countries. The probability of a first stroke or first TIA is around 1.6 per 1000 and 0.42 per 1000 respectively. In less developed regions, the average age of stroke is less due to the different population age structure, resulting from higher mortality rates.

Stroke patients are at highest risk of death in the first weeks after the event, and between 20–50 per cent die within four months depending on type, severity, age, co-morbidity and effectiveness of treatment of complications. Patients who survive may be left with no disability or with mild, moderate or severe disability. Considerable spontaneous recovery occurs up to about 6 months. However, patients with history of stroke are at high risk of a subsequent event of around 10 per cent in the first year and 5 per cent year thereafter (4).

The proportion of patients achieving independence in self-care by one year after a stroke range from around
Stroke control programme

The aim of a stroke control programme is to apply at community level effective measures for the prevention of stroke. The first priority goes to control of arterial hypertension, which is a major cause of stroke. As transient ischaemic attacks (TIA) may be one of the earliest manifestations of stroke, their early detection and treatment is important for the prevention of stroke (2). Control of diabetes, elimination of smoking, and prevention and management of other risk factors at the population level are the treatment for acute stroke is largely the control of complications. Facilities for the long-term follow-up of patients are essential. The education and training of health personnel and of the public form an integral part of the programme. For any such programme, reliable knowledge of the extent of the problem in the community concerned is essential (2).

In summary, control of stroke that was once considered an inevitable accompanying to ageing is now being equally hard in age of primary prevention. It has generated the hope that stroke can be tackled by community health action.

RHEUMATIC HEART DISEASE

Rheumatic fever (RF) and rheumatic heart disease (RHD) cannot be separated from an epidemiological point of view (3). Rheumatic fever is a febrile disease affecting connective tissues particularly in the heart and joints initiated by infection of the throat by group A beta haemolytic streptococci. Although RF is not a communicable disease, it results from a communicable disease, rheumatic fever, which is a contagions disease. The consequences of RHD include: continuing damage to the heart; increasing disabilities; repeated hospitalization, and premature death usually at the age of 35-years or even earlier. RHD is one of the most readily preventable chronic disease.

Problem

WGRLD

The incidence of rheumatic fever and rheumatic heart disease has not decreased in developing countries. Retrospective studies review developing countries to have the highest figures for cardiac involvement and recurrence rates of rheumatic fever. Worldwide, there are over 15 millions cases of RHD with 200,000 new cases. During 2008, 220,000 deaths from this disease occurred which is about 0.4 per cent of total deaths (2).

RHD is a major cause of morbidity and a major cause of mortal insufficiency and stenosis in the world. Variables that correlate with the severity of valve disease include the number of previous attacks of RF, the length of time between the onset of disease and start of therapy, and the disease
is more severe in females than in males). Insufficiency from acute rheumatic valve disease resolves in 60–80 per cent of patients who adhere to antibiotic prophylaxis (3).

In a number of affluent countries (North America, Western Europe and in Japan) the incidence of RF and the prevalence of and mortality from RHD have fallen during the last two decades, whereas the disease is now generally uncommon. Some of this decline occurred before modern treatment methods became available, indicating that the fall in prevalence and incidence was associated with social and economic changes (4).

As a result of the above decline, there has been a tendency to minimize the public health importance of RF - the assumption being that the disease may subside or even vanish spontaneously as living standards rise. However, even in the most affluent countries, there remain pockets of poverty where socio-economic conditions continue to favour the persistence of RF (5).

INDIA

In India, RHD is prevalent in the range of 5–7 per thousand in 5–15 years age group and there are about 1 million RHD cases in India. RHD constitutes 20–30% of hospital admissions due to CV disease in India (6). Streptococcal infections are very common especially in children living in under-privileged conditions, and RF is reported to occur in 1–3 per cent of those infections (7).

Jai Vagun Mission Mode project on Community Control of RF/RHD in India is being carried out with four main components, viz.: to study the epidemiology of streptococcal sore throat, establish registries for RF and RHD, vaccine development for streptococcal infection and conducting advanced studies on pathological aspects of RF and RHD (7).

Epidemiological factors

1. AGENT FACTORS

(a) AGENT: The onset of RF is usually preceded by a streptococcal sore throat. Of the streptococci, it is the group A streptococci that has been incriminated as the causative agent. It has been suggested that not all strains of group A streptococci lead to RF, but it is realized that there might be some strains with "rheumaticogenic potential". The serotype that has attracted special emphasis is M type 5 which is frequently associated with RF (8). All group A streptococci are sensitive to penicillin. Unfortunately, the group consists of a great number of immunologically different types with little cross immunity, defying all attempts to produce an effective vaccine. Recently the virus (cons/ekle B–4) has been suggested as a causative agent and streptococcal acting as a conditioning agent. There are many gaps in our knowledge about the causative agent and underlying disease mechanisms (6). CARRIERS: Carriers of group A streptococcus are frequent, e.g., convalescent, transient and chronic carriers. In view of the high carrier rate, their eradication is not even theoretically possible (9).

2. HOST AND ENVIRONMENTAL FACTORS

(a) AGE: RF is typically a disease of childhood and adolescence (5–15 years) although it also occurs in adults (20 per cent cases). Mention has already been made about the high incidence of "juvenile mitral stenosis" in India (9, 10). The initial attack of RF occurs at a young age, progresses to valvular lesions faster and is associated with pulmonary arterial hypertension. The cause of the "juvenile" disease in India is not known. (b) SEX: The disease affects both sexes equally but prognosis is worse for females than for males. (c) IMMUNITY: An immunological basis for RF and RHD has been proposed. The most prevalent concept is the toxic-immunological hypothesis. According to this theory, group A streptococcal products have certain toxic products, and components of the streptococci and of host tissues have an antigenic cross-relationship, leading to immunological processes that result in an attack of RF (11). (d) SOCIO-ECONOMIC STATUS: RF is a social disease linked to poverty, overcrowding, poor housing conditions, inadequate health services, inadequate expertise of health-care providers, and a low level of awareness of the disease in the community. It declines sharply when the standard of living is improved, but even in the most affluent countries, there are areas where the disease still exists. (e) HIGH-RISK GROUPS: The school-age children between 5 and 15 years; slum dwellers; and those living in a closed community (e.g., barracks).

Table 1 summarizes the effects of environmental factors on RF and RHD.

</tr>
<tr>
<td>Rheumatic chorea.</td>
<td>Other major manifestations or evidence of group A streptococcal infection not required.</td>
</tr>
<tr>
<td>Chronic valve lesions of RHD (patients presenting for the first time with purulent sepsis or mixed viral disease and/or aortic valve disease)</td>
<td>Do not require any other criteria to be diagnosed as having rheumatic heart disease.</td>
</tr>
</tbody>
</table>

### Major manifestations
- carditis
- polyarthritis
- chorea
- erythema marginatum
- subcutaneous nodules
- clinical; fever; polyarthralgia
- laboratory: elevated acute phase reactants (erythrocyte sedimentation rate or leukocyte count)

### Minor manifestations

### Supporting evidence of a preceding streptococcal infection within the last 45 days
- electrocardiogram: prolonged PR interval
- crescendo or rising antistreptolysin-O or other streptococcal antibody, or
- a positive throat culture, or
- rapid antigen test for group A streptococcus, or
- recent scarlet fever.

*Patients may present with polyarthritis (or only polyarthralgia or monarthralgia) and with several (3 or more) other minor manifestations, together with evidence of recent group A streptococcal infection. Some of these cases may later become rheumatic fever. It is prudent to consider them as cases of 'probable rheumatic fever' (since other diagnoses are excluded) and advise regular secondary prophylaxis. Such patients require close follow-up and regular examination of the heart. This cautious approach is particularly suitable for patients in vulnerable age groups in high incidence settings.*

### Source: (12)

### Prevention
Two preventive approaches are possible:

#### a. PRIMARY PREVENTION
The aim of primary prevention is to prevent the first attack of RF by identifying all patients with streptococcal throat infection and treating them with penicillin. While this approach is theoretically simple, in practice, it is difficult to achieve and may not be feasible in many developing countries (4). In order to prevent a single case of RF, several thousand cases of streptococcal throat infection must be identified and treated. Many infections are inapparent or if apparent are not brought to the attention of the health services; even if they are reported, quick and reliable laboratory services are needed to confirm the diagnosis. A viable approach is to concentrate on "high-risk" groups such as school-age children. They should be kept under
surveillance for streptococcal pharyngitis. Ideally a sore throat should be swabbed and cultured. If streptococci are present, the child should be put on penicillin. Since facilities for throat swab culture are not easily available, it is justified to treat a sore throat with penicillin even without having the culture. For the person, a single intramuscular injection of 1.2 million units of benzathine benzyl penicillin for adults and 600,000 units for children is adequate, or oral penicillin (Penicillin V or Post-oftac G) should be given for 10 days. This is the least expensive method of giving penicillin for eradication of streptococci from the throat. For patients with allergy to penicillin, erythromycin is the drug of choice. The MCH and school health services should be utilized for this purpose.

In short, the impossible logistics of primary prevention coupled with enormous financial constraints force us to concentrate on secondary prevention (10).

b. SECONDARY PREVENTION

Secondary prevention (i.e., the prevention of recurrences of RF) is a more practicable approach, especially in developing countries. It consists in identifying those who have had RF and giving them one intramuscular injection of benzathine benzyl penicillin (1.2 million units is adults and 600,000 units in children) at intervals of 3 weeks (12). This must be continued for at least 5 years or until the child reaches 16 years whichever is later. For patients with carditis (mild mitral regurgitation or healed carditis) the treatment should continue for 10 years after the last attack, or at least until 25 years of age, which ever is longer. More severe valvular disease or post-streptococcal glomerulonephritis cases need life-long treatment (12). This prevents streptococcal sore throat and therefore recurrence of RF and RHD.

However, the principal problem is one of patient compliance at penicillin prophylaxis is a long-term affair. Studies have shown that secondary prevention is feasible, inexpensive and effective when implemented through primary health care systems (13).

c. NON-MEDICAL MEASURES

Non-medical measures for the prevention/control of RF are related to improving living conditions, and breaking the poverty-disease-poverty cycle. Improvements in socio-economic conditions (particularly better housing) will in the long term reduce the incidence of RF.

Objective evaluation of available data indicates that penicillin alone will not lead to effective control. Predictions suggest that many of the countries which suffer severe economic constraints will not be likely to be able to raise their standards of living in the foreseeable future to significantly alter the incidence of this disease (9).

d. EVALUATION

In the evaluation of the programme, the prevalence of RHD in school children from periodic surveys of random samples is probably the best indicator. It is suggested that surveys should be carried out on samples of schools (not individuals) in the 6–14 years age group at 5-year intervals. The recommended sample size is 20,000 to 30,000 children depending upon the expected prevalence (13).

References

CANCER

Cancer may be regarded as a group of disease characterized by an (i) abnormal growth of cells (ii) ability to invade and spread to other parts of the body and (iii) the eventual death of the affected patient if the tumour has progressed beyond that stage when it can be successfully removed. Cancer can occur at any site or tissue of the body and may involve any type of cells.

The major categories of cancer are: (a) Carcinomas, which arise from epithelial cells lining the internal surfaces of the various organs (e.g. mouth, oesophagus, intestines, uterus) and from the skin epithelium; (b) Sarcomas, which arise from mesodermal cells constituting the various connective tissues (e.g. fibrous tissue, fat and bone); and (c) Lymphomas, myeloma and leukemias arising from the cells of bone marrow and immune systems.

The term "primary tumour" is used to denote cancer in the organ of origin, while "secondary tumour" denotes cancer that has spread to regional lymph nodes and distant organs. When cancer cells multiply and reach a critical size, the cancer is clinically evident as a lump or ulcer localized to the organ of origin in early stages. As the disease advances, symptoms and signs of invasion and distant metastases become clinically evident (1).

Problem statement

WORLD

In 2012, the worldwide burden of cancer rose to an estimated 14 million new cases per year, a figure expected to rise to 22 million annually within the next two decades. Over the same period, cancer deaths are predicted to rise from an estimated 8.2 million annually to 13 million per year. Globally, during 2012, the most common cancers diagnosed were those of the lung (1.8 million), breast (1.7 million) and colorectal (1.4 million). The most common causes of cancer deaths were cancer of lung (1.6 million), liver (0.8 million) and stomach (0.7 million).

As a consequence of growing and ageing populations, developing countries are disproportionately affected by the increasing numbers of cancers. More than 60 per cent of the world's total cases occur in Africa, Asia, and Central and South America, and these regions account for about 70 per cent of the world's cancer deaths. Situation is made worse by the lack of early detection and access to treatment (2). The "Westernization" trend: As low human-development index (HDI) countries become more developed through rapid societal and economic changes, they are likely to become "westernized". As such, the pattern of cancer
incidence is likely to follow that seen in high HDI settings, with
likely decline in cancer incidence rate of cervix uteri
and stomach, and increasing incidence rates of breast,
prostate and colorectal cancers. This westernisation effect is
a result of reduction in infection-related cancers and increase
in cancers associated with reproductive, dietary and
hormonal risk factors (2).

Large variations in both cancer frequency and case
fatality are observed, even in relation to the major forms of
cancer in different regions of the world for men and women.
Table 1 and 2 show the age standardized incidence and
mortality of 10 common cancers in men and women
worldwide.

For any disease, the relationship of incidence to mortality
is an indication of prognosis. Similar incidence and mortality
rates being indicative of an essentially fatal condition. Thus,
lung cancer accounts for most deaths from cancer in the
world (1.6 million annually, since it is most invariably

*Age-standardized rate (W): A rate is the number of new cases or deaths per 100 000 persons per year. An age-standardized rate is the rate that a population would have if it had a standard age structure. Standardization is necessary when comparing several populations that differ with respect to age because age has a powerful influence on the risk of cancer.

Risk of getting or dying from the disease before age 75 (%): The probability or risk of individuals getting/dying from cancer. It is expressed as the number of new born children (out of 100) who would be expected to develop/cure from cancer before the age of 75, if they had cancer in the absence of other causes of death.

Source: (4)

Associated with poor prognosis. On the other hand, appropriate intervention is often effective in avoiding fatal outcome following diagnosis of breast cancer. Hence this particular cancer, which rank second in terms of incidence, is not among the top three causes of death from cancer, which are respectively cancers of the lung, stomach, and liver.

The most conspicuous feature of the distribution of cancer rates between the sexes is the male predominance of lung cancer. Prostate, colorectal, stomach and liver cancer are also much more common in males (Table 1). Cancer of breast, colorectum, cervix, uterus, lung and stomach are common in females (4). For the most part, differences in distribution between the sexes are attributable to differences in exposure to causative agents rather than to variation in the susceptibility. For other tumour types, including cancers of pancreas and colorectum, there is little difference in the sex distribution. Generally speaking, the relationship of incidence to mortality is not affected by sex. Thus for example, the prognosis following diagnosis of liver or pancreatic cancer is dismal for both males and females. Many other tumour types are more responsive to therapy, so that cancers of breast, prostate and uterine cervix are the cause of death in only a minority of patients diagnosed (5).

The burden of cancer is distributed unequally between developed and developing countries, with particular cancer types exhibiting different patterns of distribution.

**INDIA**

In India, the National Cancer Registry Programme of the ICMR provides data on incidence, mortality and distribution of cancer from 25 population-based registries and 5 hospital-based registries.

It is estimated that during the year 2012, 10.15 lakh new cancer cases occurred in the country, of these 4.77 lakh were males and 5.37 lakh females. It gives an incidence rate of 92.4 per lakh population. Same year about 6.83 lakh persons died of cancer, (3.57 lakh males and 3.26 lakh females), a mortality rate of 69.7 per lakh population. Table 3 and 4 show the age-standardized incidence and mortality due to cancer in India.

The five most frequent cancers in men were cancer lung, lip and oral cavity, stomach, colorectum and other pharynx.

In women, cancer breast, cervix uteri, colorectum, ovary, lip and oral cavity. Cancer in males were mostly tobacco related. In women, cervical cancer is closely associated with poor genital hygiene, early consummation of marriage, multiple pregnancies, and contact with multiple sexual partners. It is also reported that breast cancer is proportionately increase in the few metropolitan areas of India. This appears to be related to late marriage, birth of the first child at a late age, fewer children, and shorter periods of breast-feeding, which are increasingly common practice among the educated urban women (7).

Facilities for screening and proper management of cancer patients are grossly limited in India. More than two-thirds of cancer patients are already in an advanced and incurable stage at the time of diagnosis. Appropriate strategies are being developed, including creating public awareness about cancer, tobacco control and application of self or assisted screening technique for oral, cervical, and breast cancers.

**Time trends**

Few decades ago, cancer was the sixth leading cause of death in industrialized countries, today, it is the second leading cause of death. There are a number of reasons for this increase, the three main ones being a longer life expectancy, more accurate diagnosis and the rise in cigarette smoking, especially among males. The overall rates do not reflect the different trends according to the type of cancer. For example, there has been a large increase in lung cancer incidence and the stomach cancer has shown a declining trend in most developed countries for reasons not understood.

**Cancer patterns**

There are widespread variations in the distribution of cancer throughout the world. That cancer of the stomach is very common in Japan, and has a low incidence in United States. The cervical cancer is high in Columbia and has a low incidence in Japan. In the South-East Asia Region of WHO, the great majority are cancers of the oral cavity and uterine cervix. These and other international variations in the

Source: (5)
pattern of cancer are attributed to multiple factors such as environmental factors, food habits, lifestyle, genetic factors or even accidents. (10) Malignant cells have a similar origin and are of carcinomas that, in the world as a whole, cigarette smoking is now responsible for more than one million premature deaths each year (10). (b) ALCOHOL: Excessive intake of alcoholic beverages is associated with oesophageal and liver cancer. Some recent studies have suggested that beer consumption may be associated with breast cancer (9). It is estimated that alcohol contributed to about 3 per cent of all cancer deaths (10). (c) DIETARY FACTORS: Dietary factors are also related to cancer. Smoked fish is related to stomach cancer, dietary fibre to intestinal cancer, beef consumption to bowel cancer and a high fat diet to breast cancer. A variety of other dietary factors such as food additives and contaminants have fallen under suspicion as causative agents. (Refer to chapter 10 for further details.) (d) OCCUPATIONAL EXPOSURES: These include exposure to benzene, arsenic, cadmium, chromium, vinyl chloride, asbestos, polychlorinated hydrocarbons, etc. Many others remain to be identified. The risk of occupational exposure is considerably increased if the individuals also smoke cigarettes. Occupational exposures are usually reported to account for 1 to 5 per cent of all human cancers (11). (e) VIRUSES: An intensive search for a viral origin of human cancers revealed that hepatitis B and C virus is causally related to hepatocellular carcinoma. The relative risk of Hepatitis B is increased in patients with HIV infection is so high that it was the first manifestation of the AIDS epidemic to be recognized. Non-Hodgkin’s lymphoma, a cancer of the lymph nodes and spleen is a late complication of AIDS. The Epstein-Barr virus (EBV) is associated with 2 human malignancies, viz. Burkitt’s lymphoma and nasopharyngeal carcinoma. Cytomegalovirus (CMV) is a suspected oncogenic agent and classical Kaposi’s sarcoma is associated with a higher prevalence of antibodies to CMV. Human papilloma virus (HPV) is a chief suspect in cancer cervix. Hodgkin’s disease is also believed to be of viral origin. The human T-cell leukemia virus is associated with adult T-cell leukemia/lymphoma in the United States and southern parts of Japan (5, 10). (2) PARASITES: Parasitic infections may also increase the risk of cancer, as for example, schistosomiasis in Middle East producing carcinoma of the bladder. (g) CUSTOMS, HABITS AND LIFESTYLES: To the above causes must be added customs, habits and lifestyles of people which may be associated with an increased risk for certain cancers. The familial examples are the demonstrated association between smoking and lung cancer, tobacco and betel chewing and oral cancer, etc (13). (h) OTHERS: There are numerous other environmental factors such as sunlight, radiation, air and water pollution, medications (e.g., oestrogen) and pesticides which are related to cancers and it is now possible to control these factors in the general population as well as in particular occupational groups. They include the following:

(a) CONTROL OF TOBACCO AND ALCOHOL CONSUMPTION: Primary prevention offers the greatest hope for reducing the number of tobacco-related cancer deaths. It has been estimated that control of tobacco smoking alone would reduce the total burden of cancer by over a million cancers each year (15). (b) PERSONAL HYGIENE: Improvements in personal hygiene may lead to declines in the incidence of certain types of cancer, e.g., cancer cervix. (c) RADIATION: Special efforts should be made to reduce the amount of radiation (including medical radiation) received by each individual to a minimum without reducing the benefits. (d) OCCUPATIONAL EXPOSURES: The occupational aspects of cancer are frequently neglected. Measures to protect workers from exposure to industrial carcinogens should be enforced in industry. (e) IMMUNIZATION: In the case of primary liver cancer, immunization against hepatitis B virus and for prevention of cancer cervix immunization against HPV presents an exciting prospect. (f) FOODS, DRUGS AND COSMETICS: Should be tested for carcinogens.
(g) AIR POLLUTION: Control of air pollution is another preventive measure. (h) TREATMENT OF PRECANCEROUS LESIONS: Early detection and prompt treatment of precancerous lesions such as cervical tears, intestinal polyps, warts, chronic gastritis, chronic cervicitis, and adenoma is one of the cornerstones of cancer prevention. (i) LEGISLATION: Legislation has also a role in primary prevention. For example, legislation to control known environmental carcinogens (e.g., tobacco, alcohol, air pollution). (j) CANCER EDUCATION: An important area of primary prevention is cancer education. It should be directed at "high-risk" groups. The aim of cancer education is to motivate people to seek early diagnosis and early treatment. Cancer organizations in many countries remind the public of the early warning signs ("danger signals") of cancer. These are:

a. a lump or hard area in the breast
b. a change in a wart or mole
c. a persistent change in digestive and bowel habits
d. a persistent cough or hoarseness
e. excessive loss of blood at the monthly period or loss of blood outside the usual dates
f. blood loss from any natural orifice
g. a swelling or sore that does not get better
h. unexplained loss of weight.

There is no doubt that the possibilities for primary prevention are many. Since primary prevention is directed at large population groups (e.g., high risk groups, school children, occupational groups, youth clubs), the cost can be high and programmes difficult to conduct. Primary prevention, although a hopeful approach, is still in its early stages. Major risk factors have been identified for a small number of cancers only and far more research is needed in that direction.

2. SECONDARY PREVENTION

Secondary prevention comprises the following measures:

i) CANCER REGISTRATION

Cancer registration is a sine qua non for any cancer control programme. It provides a base for assessing the magnitude of the problem and for planning the necessary services. Cancer registries are basically of two types: hospital-based and population based. (a) HOSPITAL-BASED REGISTRIES: The hospital-based registry includes all patients treated by a particular institution, whether inpatients or out-patients. Registries should reflect the uniform minimum set of data recommended in the "WHO Handbook for Standardized Cancer Registers" (16). If there is a long-term follow-up of patients, hospital-based registries can be of considerable value in the evaluation of diagnostic and treatment programmes. Since hospital populations will always be a selected population, the use of these registries for epidemiological purposes is thus limited.

(b) POPULATION-BASED REGISTRIES: A right step is to set up a hospital-based cancer registry and extend the same to a "population-based cancer registry". The aim is to cover the complete cancer situation in a given geographic area. The optimum size of base population for a population-based cancer registry is in the range of 2-7 million (17). The data from such registries alone can provide the incidence rate of cancer and serve as a useful tool for initiating epidemiological studies into causes of cancer surveillance of time trends, and planning and evaluation of operational activities in all major areas of cancer control.

ii) EARLY DETECTION OF CASES

Cancer screening is the major weapon for early detection of cancer at a pre-invasive (in situ) or pre-malignant stage. Effective screening programmes have been developed for cervical cancer, breast cancer and oral cancer. Like primary prevention, early diagnosis has to be conducted on a large scale; however, it may be possible to increase the efficiency of screening programmes by focusing on high-risk groups. Clearly, there is no point in detecting cancer at an early stage unless facilities for treatment and after-care are available. Early detection programmes will require mobilization of all available resources and development of a cancer infrastructure starting at the level of primary health care, with multidisciplinary cancer centres or institutions at the state or national levels.

iii) TREATMENT

Treatment facilities should be available to all cancer patients. Certain forms of cancer are amenable to surgical removal, while some others respond favourably to radiation or other therapies. Since most of the known methods of treatment have complementary effect on the ultimate outcome of the patient, multi-modality approach to cancer control has become a standard practice in cancer centres all over the world. In the developed countries today, cancer treatment is geared to high technology. For those who are beyond the curable stage, the goal must be to provide pain relief. A largely neglected problem in cancer care is the management of pain. The WHO has developed guidelines on relief of cancer pain (18). "Freedom from cancer pain" is now considered a right of cancer patients.

CANCER SCREENING

In the light of present knowledge, early detection and prompt treatment of early cancer and precancerous conditions provide the best possible protection against cancer for the individual and the community. Now a good deal of attention is being paid to screening for early detection of cancer. This approach, that is, cancer screening may be defined as the "search for unrecognized malignancy by means of rapidly applied tests". Cancer screening is possible because:

(a) in many instances, malignant disease is preceded for a period of months or years by a premalignant lesion, removal of which prevents subsequent development of cancer;
(b) most cancers begin as localized lesions and if found at this stage a high rate of cure is obtainable; and (c) as much as 75 per cent of all cancers occur in body sites that are accessible.

METHODS OF CANCER SCREENING

(a) Mass screening by comprehensive cancer detection examination: A rapid clinical examination, and examination of one or more body sites by the physician is one of the important approaches for screening for cancer. (b) Mass screening at single sites: This comprises examination of single sites such as uterine cervix, breast or lung. (c) Selective screening: This refers to examination of those people thought to be at special risk, for example, parous women of lower socioeconomic status upwards of 35 years of age for detection of cancer cervix, chronic smokers for lung cancer, etc.
1. Screening for cervical cancer

Screening for cervical cancer has become an accepted clinical practice. The prolonged early phase of cancer in situ can be detected by a Pap smear (vaginal cytology). The screening criteria that all women should have a Pap test (cervical smear) at the beginning of sexual activity, and then every 3 years thereafter (19), is recommended. Organized population-based screening programmes have reduced the incidence and mortality from cervical cancer in many developed countries.

However, screening for cancer cervix using Pap smear requires excessive resources in terms of laboratories, equipment and trained personnel. This has led to search for an alternative screening method that can be more cost-effective. Visual inspection based screening tests such as visual inspection with 5% per cent acetic acid (VIA), VIA with magnification (VIAM), and visual inspection post application of Lugol's iodine (VILI) are some of the alternative screening tests, which have been studied for their effectiveness in India. Sensitivity of VIA tends to be similar to cytology based screening. It is easy to carry out and easy to train appropriate health workers (20).

The present strategy is to screen women using visual inspection after application of freshly prepared 5 per cent acetic acid solution (5 ml of glacial acetic acid mixed with 95 ml distilled water). Detection of well-defined opaque acetowhite lesion close to the squamosa-columnar junction, well defined circum-oralificial acetowhite lesion or dense acetowhiting of ulceroproliferative growth on cervix constitute a positive VIA or VIAM. The test is followed by a single visit approach for further investigation and management. The screening clinic is usually planned as a part of the medical structure of the hospital is planned in such a way that the treatment based on colposcopy is offered in the same visit. Pap smear and biopsy investigations that are done to ensure that there are cytological and histopathological back-up for the interventions (20).

Intensive information, education and communication activities are required to sensitize the community about the significance of the disease and its early detection through screening.

2. Screening for breast cancer

There is evidence that screening for breast cancer has a favourable effect on mortality from breast cancer. The basic techniques for early detection of breast cancer are:

(a) breast self-examination (BSE) by the patient
(b) palpation by a physician (c) thermography, and (d) mammography.

All women should be encouraged to perform breast self-examination. Breast cancers are more frequently found by women themselves than by a physician during a routine examination. Although the effectiveness of BSE has not been adequately quantified, it is a useful adjuvant to early case detection. In many countries, BSE will probably be the only feasible approach to widespread case detection for a long time to come. Palpation is unreliable for large fatty breasts. Thermography has the advantage that the test is not exposed to radiation. Unfortunately, it is not a sensitive tool. Mammography is the most sensitive and specific in detecting small tumours that are sometimes missed on palpation. The use of mammography has three potential drawbacks: (i) exposure to radiation. This may amount to a dose of less than 0.5 millirems. This is compared to a 30-40 millirem dose received in chest X-ray. Therefore, there has been concern about exposure to radiation from repeated mammographies and the risk of breast cancer developing as a result (21). The test requires specific technical equipment and more sophisticated facilities.

3. Screening for lung cancer

At present there are only two techniques for screening for lung cancer, viz. chest radiograph and sputum cytology. Mass radiography has been suggested for early diagnosis at six monthly intervals, but the evidence in support of this is not convincing. So it is recommended. It is doubtful whether the disease satisfies the criteria for suitability for screening (see chapter 4).

Epidemiology of Selected Cancers

1. Oral cancer

Oral cancer is one of the ten most common cancers in the world. Its high frequency in Central and South East Asian countries (e.g. India, Bangladesh, Sri Lanka, Thailand, Indonesia, Pakistan) has been well documented. It is estimated that during the year 2012, about 1.98 lac new cases and 98,000 deaths occurred worldwide, with a mortality rate of 2.1 per lac population (4).

Problem in India

For the year 2012, with estimated incidence of 10.1 cases per 100,000 population: for males and 4.3 per 100,000 population in females, oral cancer is a major problem in India. The estimated mortality is about 7 per 100,000 in males and 3.0 per 100,000 in females. During the year, 77,003 new cases occurred in the country with 52,067 deaths due to oral cancer (4).

Epidemiological Features

(a) Tobacco: Approximately 90 per cent of oral cancers in South East Asia are linked to tobacco chewing and tobacco smoking. During 1966-1977, a large epidemiological survey was carried out in different parts of the country. In this 10-year follow-up study of 30,000 individuals in the three districts of Ernakulam (Kerala), Srikakulam (Andhra), and Bhavnagar (Gujarat), the results indicated that (i) oral cancer and precancerous lesions occurred almost solely among those who smoked or chewed tobacco, and (ii) oral cancer was almost always preceded by some type of precancerous lesions (24, 25). The case about tobacco is further strengthened by the findings that the cancer almost always occurred on the side of the mouth where the tobacco quid was kept (25), and the risk was 36 times higher for non-chewers if the quid was kept in the mouth during sleep (26).

(b) Alcohol: Data indicates that oral cancer can also be caused by high concentrations of alcohol, and that alcohol appears to have a synergistic effect in tobacco users (23).
2. Cancer of the cervix

This is the second most common cancer among women worldwide, with an estimated 527,634 new cases and 265,653 deaths with overall incidence, mortality ratio of 52 per cent (6). Developing countries, where it is often the most common cancer among women, account for 88 per cent of cases. Wide variations in incidence and mortality from the disease exist between countries. Cases and deaths have declined markedly in the last 40 years in most industrialized countries, partly owing to a reduction in risk factors, but mainly as a result of extensive screening programmes. More limited improvements have been observed in developing countries, where persistently high rates tend to be the rule (7).

In India, cancer of the cervix is the second most common cancer in women. It is estimated that during 2012, 122,644 new cases of cancer cervix occurred in the country (incidence rate of 22.6 per lakh population) and about 67,477 women died of the disease (mortality rate of 12.4 per lakh population). It comes to 20.7 per cent of all cancer deaths in women and about 9.9 per cent of total cancer deaths in the country (6).

NATURAL HISTORY
(a) the disease: Cancer cervix seems to follow a progressive course from epithelial dysplasia to carcinoma in situ to invasive carcinoma (Fig. 1). There is good evidence that carcinoma in situ persists for a long time, more than 8 years on an average (19). The proportion of cases progressing to invasive carcinoma from preinvasive stage is not known – it may average 15 to 20 years or longer (31). The duration of the preinvasive stage is also not known. There is evidence that some in situ will spontaneously regress without treatment. Once the invasive stage is reached, the disease spreads by direct extension into the lymph nodes and pelvic organs.

![FIG 1](image)

Hypothetical model of the natural history of cancer cervix

(b) a causal agent: There is evidence pointing to Human papilloma virus (HPV) – sexually transmitted – as the cause of cervical cancer (32). This virus was once supposed to produce only vegetant warts, but now acknowledged as responsible for a much wider clinical and subclinical lesions. The virus is found in more than 95% of the cancers. Current evidence suggests that the virus is a necessary, but not sufficient cause of the disease and researchers are now trying to define other co-factors.

RISK FACTORS
(a) age: Cancer cervix affects relatively young women with incidence increasing rapidly from the age of 25 to 45, then level off, and finally fall again. (b) SEARING: WARTS: Past and/or present occurrence of clinical genital warts has been found to be an important risk factor (32). (c) MARITAL STATUS: Cases are less likely to be single, more likely to be widowed, divorced or separated and having multiple sexual partners. The fact that cancer of the cervix is very common in prostitutes and practically unknown among virgins suggests that the disease could be linked with sexual intercourse. (d) EARLY MARRIAGE: Early marriage, early coitus, early childbearing and repeated

PREVENTION

a PRIMARY PREVENTION

Oral cancer is amenable to primary prevention. If the tobacco habits are eliminated from the community, a great deal of减少 incidence of oral cancer can be achieved. This requires intensive public education and motivation for changing lifestyles supported by legislative measures like banning or restricting the sale of tobacco.

b SECONDARY PREVENTION

Oral cancers are easily accessible for inspection allowing early detection. If detected early, possibly at the pre-cancerous stage, they can be treated or cured. The pre-cancerous lesions can be detected for up to 15 years, prior to their change to an invasive carcinoma. Leukoplakia can be cured by cessation of tobacco use. The main treatment modalities that offer hope are surgery and radiotherapy (29). In developing countries over 50 per cent of oral cancers are detected only after they have reached an advanced stage (14).

The primary health care workers (village health guides, and multi-purpose workers) are in a strategic position to detect oral cancers at an early stage during home visits. They can prove to be a vital link and a key instrument in the control of oral cancer in developing countries (30).
childbirth have been associated with increasing risk. (e) ORAL CONTRACEPTIVE PILLS: There is renewed concern about the possible relationship between pill use and the development of invasive cervical cancer (33). A recent WHO study finds an increased risk with increased duration of pill use and with the use of oral contraceptives high in oestrogen (34). (f) SOCIO-ECONOMIC CLASS: Cancer cervix is more common in the lower socio-economic groups reflecting probably poor genital hygiene.

PREVENTION AND CONTROL

(a) PRIMARY PREVENTION: Until the causative factors are more clearly understood, there is no prospect of primary prevention of the disease (31). It may be that with improved personal hygiene and birth control, cancer of the cervix will show the same decline in developing countries as already experienced in most of Europe and North America (35).

(b) SECONDARY PREVENTION: This rests on early detection of cases through screening and treatment by radical surgery and radiotherapy. The 5-year survival rate is virtually 100 percent for carcinoma in situ, 79 percent for local invasive disease and 45 percent for regional invasive disease (19). Cancer cervix is difficult to cure once symptoms develop and is fatal if left untreated. Prognosis is strongly dependent upon the stage of disease at detection and treatment.

3. Breast cancer

Breast cancer is by far the most frequent cancer among women, with an estimated 1.67 million new cases diagnosed in 2012 (about 25 percent of all cancers). It is now the most common cancer both in developed (794,000 cases) and developing regions (883,000 cases). Incidence rates vary from 27 per 100,000 women in Eastern Africa to 98 per 100,000 women in Western Europe. The range of mortality rate is similar, approximately 6-20 per 100,000, because of the more favourable survival of breast cancer cases in developed countries. As a result, breast cancer ranks as the fifth cause of death from cancer, but it is still the most frequent cause of cancer death in women in developing regions (36).

It is estimated that during the year 2012, about 144,937 new cases of breast cancer in women occurred in India, which accounts for 27.0 per 100,000 of all malignant cases (an incidence rate of 25.8 per 100,000 population). About 70,218 women died of this cancer (mortality of 21.5 per 100,000 of all cancer cases), mortality rate being 12.7 per 100,000 population, ranking number one killer in women (6).

RISK FACTORS

The established risk factors of breast cancer include the following:

(a) AGE: Breast cancer is uncommon below the age of 35, the incidence increasing rapidly between the ages of 35 and 50. A slight bimodal trend in the age distribution has been observed (37) with a dip in incidence at the time of menopause. A secondary rise in frequency often occurs after the age of 65. Women who developed their first breast cancer under the age of 40, had three times the risk of developing a second breast cancer than did those who developed their first cancer after the age of 40 (38). Indeed the aetiologies of pre-menopausal and post-menopausal breast cancer appears to be different (39).

Breast cancer is not only infrequent in Indian women, but also it occurs in them a decade earlier than in Western women — the mean age of occurrence is about 62 in India, as compared to 53 in the white women.

(b) FAMILY HISTORY: The risk is high in those with a positive family history of breast cancer, especially if a mother or sister developed breast cancer when pre-menopausal.

(c) PARITY: MacMahon, et al (40) in their international case-control study found that the risk of breast cancer is directly related to the age at which women bear the first child. An early first, long-term pregnancy seems to have a protective effect. Those whose first pregnancy is delayed to their late thirties are at a higher risk than multiparous women. Unmarried women tend to have more breast cancer than married single women, and nulliparous women had the same risk.

(d) AGE AT MENARCHE AND MENOPAUSE: Early menarche and late menopause are established risk factors (41). The risk is reduced for those with a surgically induced menopause. Forty or more years of menstruation doubles the risk of breast cancer as compared with 30 years (42).

(e) HORMONAL FACTORS: The association of breast cancer with early menarche and late menopause suggests that estrogens appear to play a crucial role in the development of breast cancer. Evidence suggests that both elevated oestrogen as well as progesterone are important factors in increasing breast cancer risk (43). In short, hormones appear to hold the key to the understanding of breast cancer.

(f) PRIOR BREAST BIOPSY: Prior breast biopsy for benign breast disease is associated with an increased risk of breast cancer.

(g) DIET: Current aetiological hypotheses suggest that cancer of the breast is linked with a high fat diet and obesity. It is not known how dietary fat influences breast cancer risk at a cellular level (45).

(h) SOCIO-ECONOMIC STATUS: Breast cancer is common in higher socio-economic groups. This is explained by the high level of birth control.

(i) OTHERS: (1) Radiation: An increased incidence of breast cancer has been observed in women exposed to radiation. The aetiologies of pre-menopausal and post-menopausal breast cancer appears to have little overall effect on breast cancer, although prolonged use of oral pills before the first age of 25 may increase the risk in younger women (44).

PREVENTION

a PRIMARY PREVENTION

Current knowledge of the aetiology of breast cancer (35) offers little prospect of primary prevention. However, the aim should be towards elimination of risk factors discussed above and promotion of cancer education. The average age at menarche can be increased through a reduction in childhood obesity, and an increase in strenuous physical activity; and the frequency of ovulation (after menarche) decreased by an increase in strenuous physical activity (45).

There is also good reason for reducing fat intake in the diet.

b. SECONDARY PREVENTION

Breast screening leads to early diagnosis of breast cancer,
which in turn influences treatment and, hopefully, mortality. An important component of secondary prevention is follow-up; to detect cancer in the opposite breast at an early stage; and to generate research data that might be useful (39).

No major improvement in survival rates has yet been shown by current treatment modalities. Some cases progress rapidly even if diagnosed as an apparently early stage, others surviving for 20 years even after metastatic spread. However, in general, the removal of the tumour early is more likely to be curative than removal at a later stage (29).

4. Lung cancer

MAGNITUDE OF THE PROBLEM

Lung cancer has been known in industrial workers from the late 19th century. It came into prominence as a public health problem in the Western world in 1930s - at first in men, and later (in 1960s) among women (46). and has followed the increasing adoption of cigarette smoking first by men and later by women. According to WHO reports, between 1950 and 1980, the death rate due to lung cancer increased by 76 per cent in men and by 135 per cent in women (47, 27). In countries where cigarette smoking has only recently begun to be widely adopted, lung cancer deaths still remain low, but it may be expected that they will soon. In others, such as Poland, where the use of cigarettes began earlier, the rise is already occurring. The total burden of lung cancer in any country is directly related to the amount and duration of cigarette smoking.

Lung cancer has been the most common cancer in the world for several decades, and by 2012, there were an estimated 1.85 million new cases, representing 13.0% of all new cancers. It was also the most common cause of death from cancer, with 1.58 million deaths (19.4% of the total).

A majority of the cases now occur in the developing countries (55%). Lung cancer is still the most common cancer in men worldwide (16.5% of the total). In females, incidence rates are generally lower, but worldwide, lung cancer is now the fourth most frequent cancer of women (8.5% of all cancers) and the second most common cause of death from cancer (12.8% of the total). The highest incidence rate is observed in Northern America (where lung cancer is now the second most frequent cancer in women), and the lowest in Middle Africa (25th most frequent cancer).

Because of its high fatality (the ratio of mortality to incidence is 0.86) and the lack of variability in survival in developed and developing countries, the higher and lower mortality rates are estimated in the same regions, both in men and women (48).

The estimates for the year 2012 for India are about 70,276 new lung cancer cases of which 53,728 were men and 16,547 women (incidence rate of 6.9 per 100,000 population). About 63,759 persons died of lung cancer during the same year, of which 68,697 were men and 15,062 women (a mortality rate of 6.3 per 100,000 population). It accounts for 6.9 per cent of all malignancies and 1.9 per cent of all deaths due to cancer at the country (6).

EPIDEMIOLOGICAL FEATURES

a. Age AND SEX

About a third of all lung cancer deaths occur below the age of 65. In many industrialized countries, the incidence of lung cancer is at present increasing more in females than in males (49).

b. RISK FACTORS

(i) Smoking: Tobacco smoking was first suggested as a cause of lung cancer in the 1920s. Subsequent studies proved the causal relationship between cigarette smoking and lung cancer. Two studies in India showed that the lung cancer risk for cigarette smokers is 8.6 times the risk for non-smokers (50, 51). The risk is strongly related to the number of cigarettes smoked, the age of starting to smoke and smoking habits, such as inhalation and the number of puffs and the nicotine, the tar content and the length of cigarettes. Those who are highly exposed to "passive smoking" (somebody else's smoke) are at an increased risk of developing lung cancer. It has been calculated that in countries where smoking has been a widespread habit, it is responsible for 90 per cent of lung cancer deaths (52). The strongest evidence that cigarette smoking is responsible for lung cancer is the incidence reduction that occurs after cessation of smoking. This has been convincingly demonstrated in a 50-year prospective study on male British doctors (53).

The most noxious components of tobacco smoke are tar, carbon monoxide and nicotine. The carcinogenic role of tar is well established. Nicotine and carbon monoxide, particularly, contribute to increased risk of cardiovascular diseases through enhancement of blood coagulation in the vessels, interference with myocardial oxygen delivery, and reduction of the threshold for ventilatory stimulation (8).

A study in India has shown that there is no difference between the tar and nicotine delivery of the filter and non-filter cigarettes smoked in India, so that a filter gives no protection to Indian smokers. The "king-size" filter cigarettes deliver more tar and nicotine than ordinary cigarettes. But smoking appears to carry a higher lung cancer risk than cigarette smoking owing to the higher concentration of carcinogenic hydrocarbons in the smoke (8).

(ii) Other factors: Besides cigarette smoking, there are other factors which are implicated in the aetiology of lung cancer. These include air pollution, radioactivity, and occupational exposure to asbestos, arsenic and its compounds, chronic irritation particles containing polycyclic aromatic hydrocarbons and certain nickel-bearing dusts. A number of studies have shown an interaction between smoking and asbestos exposure.

PREVENTION

1. PRIMARY PREVENTION

In lung cancer control, primary prevention is of greatest importance. The most promising approach is to control the "smoking epidemic", because 80 to 90 per cent of all cases of lung cancer in developed countries are due to smoking of cigarettes (56). Methods of controlling the smoking epidemic have been determined by the WHO expert committee in their report (49, 55). Broadly these methods include:

a. Public Information and education
b. Legislative and restrictive measures
c. Smoking cessation activities
d. National and international coordination
a. Public information and education
The need of the hour is to create public awareness about the hazards of smoking through mass media. The target population should be the entire population with greater emphasis laid on young people and school children. Nothing less than a national anti-smoking campaign will be needed to change human behaviour or life styles associated with smoking. Curtailment of smoking must be an essential part of national health policy.

b. Legislative and restrictive measures
Legislation and restrictive measures have been suggested in the following areas: control of sales promotion; health warnings on cigarette packets and advertisements; product description showing yield of harmful substances; imposition of upper limits for harmful substances in smoking materials; taxation; sales restrictions; restriction on smoking in public places; restriction on smoking in places of work, etc. (52).

The Government of India has provided legislative support to the anti-smoking campaign. "The Cigarettes (Regulation of Production, supply and distribution) Act of 1975" which came into force from 1 April 1975, requires all manufacturers or persons trading in cigarettes to display prominently the statutory warning “Cigarette Smoking is Injurious to Health” on all cartons or packets of cigarettes that are put on sale. Most of the State Governments in India have promulgated laws prohibiting smoking in closed areas, e.g., cinemas, buses, educational institutions, and hospitals. Again in the year 2003, a comprehensive tobacco control legislation titled “The Cigarettes And Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act 2003” was passed by the Govt of India. Refer to chapter 7 “National cancer control programme” for the details.

c. Smoking cessation activities
Research continues on different methods of smoking cessation. In all countries well over 90 percent of those who give up smoking do so of their own volition, i.e., without use of any specific therapy. The basic role of most treatments for smoking cessation would be to reduce the smoker of “abstinence symptoms” (e.g., sleeplessness, craving for smoking, dizziness, constipation, etc). The report of the WHO expert committee (52) on smoking control contains information on specific smoking cessation methods such as smoking cessation clinics, nicotine substitutes, hypnosis, etc.

d. National and International coordination
Since smoking is a worldwide epidemic, it requires coordinated political and non-political approaches at local, national and international levels to contain the smoking epidemic.

2. SECONDARY PREVENTION
This rests on early detection of cases and their treatment. At present, there are only two procedures -ealpise of detecting presymptomatic, early-stage lung cancer. These are the chest X-ray and sputum cytology. But screening for early-stage lung cancer is less attractive, more expensive and appears to have less potential for reducing mortality than primary prevention. Therefore, mass screening for lung cancer is not recommended as a routine public health policy (49).

Efforts to find effective treatment for lung cancer have met with only limited success. For untreated patients, the median survival is 2 to 3 months, compared to 10-14 months for patients receiving combined chemotherapy. In view of these limitations, primary prevention merits greater attention. An important part of treatment is relief of pain so that each dying patient has the right to spend his last days as pain-free as possible.

5. Stomach cancer
About one million new cases of stomach cancer were estimated to have occurred in 2012 (6.8% of the total), making it currently the fifth most common malignancy in the world, behind cancers of the lung, breast, colorectum and prostate. More than 70%, (677,000) of cases occur in developing countries (456,000 in men, 221,000 in women), and half the world total occurs in Eastern Asia (mainly in China).

Stomach cancer is the third leading cause of cancer death in both sexes worldwide (8.9% of the total). The highest mortality rates are estimated in Eastern Asia (24 per 100,000 in men, 9.8 per 100,000 in women), the lowest in Northern America (2.8 and 1.5 respectively) (54).

About 63,097 new cases of stomach cancer were estimated to have occurred in India during 2012 [an incidence rate of 5.2 cases per lac population] of these 43,386 were in men and 19,711 in women. About 59,041 persons died of stomach cancer (mortality rate of 5.7 per lac population) of which 40,721 were men and 18,320 women (6).

The constant decline of stomach cancer in industrialized countries is linked to improved food preservation practices; better nutrition more rich in vitamins from fresh vegetables and fruits; and less consumption of preserved, cured and salted foods. Infection with the bacterium Helicobacter pylori contributes to the risk, probably by interacting with the other factors.

Symptoms are non-specific; which explains why most of the cases are diagnosed when the disease is at an advanced stage. Presentation may comprise weight loss, fatigue or gastric discomfort. Diagnosis is performed by barium X-rays and with biopsy.

Stomach cancer cases are treated by surgical removal of the tumour, with or without adjuvant chemotherapy.

Stomach cancer cases have a generally poor survival prognosis, averaging no more than 20% survival after five years. If the tumour is localised to the stomach, 60% of patients survive five years or more. However, only 18% of all cases are diagnosed at this early stage. Screening by photofluoroscopy has been widespread in Japan since the late 1960s and mortality rates are declining. It is unclear whether this trend can be attributed to mass screening alone.

**Classification**

The classification adopted by WHO (2) is given in Table 1.

**TABLE 1**

**Clinical classification of diabetes mellitus**

1. Diabetes mellitus (DM)
   - Type 1 (insulin-dependent diabetes mellitus)
   - Type 2 (non-insulin-dependent diabetes mellitus)
   - Gestational diabetes mellitus (GDM)

2. Impaired glucose tolerance (IGT)

3. Gestational diabetes mellitus (GDM)

**Source**

Type 1 diabetes (insulin-dependent diabetes mellitus) is the most severe form of the disease. Its onset is typically abrupt and it is usually seen in individuals less than 30 years of age. It is lethal unless promptly diagnosed and treated.

This form of diabetes is immune-mediated in over 90% of cases and is idiopathic in less than 10% of cases. The rate of destruction of pancreatic β cells is quite rapid. Rapid in some individuals and slow in others. Type 1 diabetes is usually associated with ketosis in its untreated state. It occurs mostly in children, the incidence is highest among 10–14 year old group, but occasionally occurs in adults. It is a catastrophic disorder in which circulating insulin is virtually absent, plasma glucagon is elevated, and the pancreatic β cells fail to respond to all insulinogenic stimuli. Exogenous insulin is therefore required to reverse the catastrophic state, prevent ketosis, reduce the hyperglycaemia, and reduce blood glucose (3).

Type 2 diabetes is much more common than type 1 diabetes. It is often discovered by chance. It is typically gradual in onset and occurs mainly in the middle-aged and elderly, frequently mild, slow to ketosis and is compatible with long survival if given adequate treatment. Its clinical picture is usually complicated by the presence of other diabetes processes.

Impaired glucose tolerance (IGT) describes a state intermediate—"at-risk" group—between diabetes mellitus and normality. It can only be defined by the oral glucose tolerance test (see Table 3).

**Insulin resistance syndrome (Syndrome X)**

In obese patients with type 2 diabetes, the association of hyperglycaemia, hyperinsulinaemia, dyslipidaemia and hypertension, which leads to coronary artery disease and stroke, may result from a genetic defect producing insulin resistance, with the latter being exaggerated by obesity. It has been proposed that insulin resistance predisposes to hyperglycaemia, which results in hyperinsulinemia (which may or may not be of sufficient magnitude to correct the insulin resistance) and this excessive insulin level then
contributes to high levels of triglycerides and increased sodium retention by renal tubules, thus inducing hypertension. High levels of insulin can stimulate endobrial proliferation to initiate arteriosclerosis (9).

Problem statement

WORLD

Diabetes is an "iceberg" disease. Although increase in both the prevalence and incidence of type 2 diabetes have occurred gloably, they have been especially dramatic in societies in economic transition, in newly industrialized countries and in developing countries. Currently the number of cases of diabetes worldwide is estimated to be around 347 million, of these more than 90 per cent are type 2 diabetes. In 2008, an estimated 1.2 million people died from consequences of high blood sugar (4). More than 60 per cent diabetes deaths occur in low and middle income countries. The apparent prevalence of hyperglycaemia depends on the diagnostic criteria used in epidemiological surveys. The global prevalence of diabetes in 2008 was estimated to be 10% in adults aged 25+ years. The prevalence of diabetes was highest in the Eastern Mediterranean Region and the Region of the Americas (11% for both sexes) and lowest in the WHO European and Western Pacific Regions (9% for both sexes). The magnitude of diabetes and other abnormalities of glucose tolerance are considerably higher than the above estimates if the categories of "impaired fasting" and "impaired glucose tolerance" are also included. The estimated prevalence of diabetes was relatively consistent across the income groupings of countries. Low-income countries showed the lowest prevalence (6% for both sexes), and the upper-middle-income countries showed the highest (10% for both sexes) (5).

Unfavorable modulation of lifestyle and dietary habits that are associated with urbanization are believed to be the most important factors for the development of diabetes. The prevalence of diabetes is approximately twice in urban areas than in rural population.

A bulk of evidence from studies on migrants indicates that the ethnic, presumably genetic, vulnerability of Asians manifests into diabetes when subjected to unfavorable lifestyles. Population-based surveys completed recently in Bangladesh, India and Indonesia have shown considerable increase in the prevalence rate of the disease in both urban and rural dwellers when compared to results obtained earlier.

Diabetic patients, if undiagnosed or inadequately treated, develop multiple chronic complications leading to irreversible disability and death. Coronary heart disease and stroke are more common in diabetics than in the general population. Microvascular complications like diabetic renal disease and diabetic retinopathy and neuropathy are serious health problems resulting in deterioration of the quality of life and premature death. In fact, diabetes is listed among the five most important determinants of the cardiovascular disease epidemic in Asia. Lower limb amputation are at least 10 times more common in diabetic than in non-diabetic individuals in developed countries, more than half of all non-traumatic lower limb amputations are due to diabetes (5). Metabolic disorders in pregnant diabetic women as well as those caused by gestational diabetes (diabetes diagnosed for the first time during pregnancy) pose a high health risk, to both the mother and foetus.

Unfortunately, there is still inadequate awareness about the real dimension of the problem among the general public. There is also a lack of awareness about the existing interventions for preventing diabetes and the management of complications. Inadequacy in primary health care systems, which are not designed to cope with the additional challenges posed by the chronic non-communicable diseases, result in poor detection of cases, suboptimal treatment and insufficient follow up leading to unnecessary disabilities and severe complications, often resulting in early death.

The age-adjusted mortality rates among the people with diabetes are 1.5 to 2.5 times higher than in the general population (6). In Caucasian population, much of the excess mortality is attributable to cardiovascular disease, especially coronary heart disease; amongst Asian and American Indian population, renal disease is a major contributor (6); whereas in some developing societies, infections are an important cause of death. It is conceivable that the decline in mortality due to coronary heart disease which has occurred in many affluent countries may be halved or even reversed if rates of type 2 diabetes continue to rise. This may occur if the coronary risk factors associated with diabetes increase to the extent that the risk they mediate outweighs the benefit accrued from improvements in conventional cardiovascular risk factors, and the improved care of patients with established cardiovascular disease (6).

In addition to non-insulin dependent diabetes, which is rather silent, chronic, often unidentified killer mostly among the adult population, the insulin dependent form of the disease (type 1) makes an even more dramatic appearance in affected children. They develop symptoms of ketoacidosis and often die, since the majority do not have access to adequate medical care, and since insulin is not available or too expensive. It is estimated that the prevalence of type 1 diabetes in Asia is relatively low, accounting for about 9.7 per cent of all diabetes mellitus cases in the Region. The insulin dependent diabetes registry at Chennai (India) reported an incidence of 10.5 per 100,000 children in the age group of 10–12 years (7).

INDIA

The population in India has an increased susceptibility to diabetes mellitus. This propensity was demonstrated by multiple surveys of migrant Indians residing in Fiji, Singapore, South Africa, U.K. and USV. The rates of diabetes in migrants from the Indian subcontinent have consistently shown to exceed those of the local population.

The results of prevalence studies of diabetes mellitus in India were systematically reviewed with emphasis on those utilizing the standard WHO criteria for diabetes diagnosis. During the year 2004, there were an estimated 37.7 million cases of diabetes in the country, of these 31.4 million were newly confirmed. The estimated total mortality due to diabetes was 1.09 lac; 62.5 thousand in urban areas and 46.6 thousand in rural areas. Same year 2.2 million DALY's were lost due to the disease (8).

Natural history

Epidemiological determinants

1. AGENT
   - The underlying cause of diabetes is insulin deficiency which is absolute in type 1 diabetes and partial in type 2 diabetes. This may be due to a wide variety of mechanisms:
   - pancreatic disorders - inflammatory, neoplastic and
other disorders such as cystic fibrosis, (b) defects in the formation of insulin, e.g., synthesis of an abnormal, biologically less active insulin molecule; (c) destruction of beta-cells, e.g., viral infection or B-cellopathy. On immune basis, (d) decreased insulin sensitivity, due to decreased numbers of adipocyte surface receptors; (e) defects, e.g., mutation of insulin gene; and (f) autoimmunity. Evidence is accumulating that the insulin response to glucose is the influence of recall immune. The overall effect of these mechanisms is reduced utilization of glucose which leads to hyperglycemia accompanied by glycosuria.

2. HOST FACTORS
(a) AGE: Although diabetes may occur at any age, surveys indicate that prevalence rises steeply with age. Type 2 diabetes usually comes to light in the middle years of life and thereafter begins to rise in frequency. Malnutrition related diabetes affects large numbers of young people. The prognosis is worse in younger diabetics who tend to develop complications earlier than older diabetics. (b) SEX: In some countries (e.g., UK) the overall male:female ratio is about equal; (c) in south-east Asia, an excess of male diabetes has been observed, but this is open to question. (c) GENETIC FACTORS: The genetic nature of diabetes is undisputed. Studies showed that in identical twins who developed type 2 diabetes, concordance was approximately 90 per cent (2), thus demonstrating a strong genetic component. In type 1 diabetes, the concordance was only about 50 per cent indicating that type 1 diabetes is not totally a genetic entity. (d) GENETIC MARKERS: Type 1 diabetes is associated with HLA-B8 and B3, and more powerfully with HLA-DR3 and DR4. The highest risk of type 1 diabetes is carried by individuals who have at least one gene of HLA-B8 and B3, and type 2 diabetes is not HLA-associated (2). (e) IMMUNE MECHANISMS: There is some evidence of (o) genetic mediated and of hormonal activity against islet cells. Some people appear to have defective immunological response to insulin and the use of oral glucometers, a type of "trigger" attack their own insulin producing cells. (f) OBESITY: Obesity particularly central adiposity has long been accepted as a risk factor for type 2 diabetes and the risk is related to both the duration and degree of obesity. The association has been repeatedly demonstrated in longitudinal studies in different populations. With a striking gradient of risk apparent with increasing level of BMI, adult weight gain, waist circumference or waist to hip ratio. Indeed, weight circumference or waist to hip ratio (reflecting abdominal or visceral adiposity) are more powerful determinants of subsequent risk of type 2 diabetes than BMI (5). Central obesity is also an important determinant of insulin resistance, the underlying abnormality in most cases of type 2 diabetes. In some instances obesity reduces the number of insulin receptors on beta cells. Voluntary weight loss improves insulin sensitivity and is several randomized controlled trials has shown to reduce the risk of progression from normal glucose tolerance to type 2 diabetes (10, 11). However, many obese subjects are not diabetic. Thus obesity by itself is inadequate to account for all, or even most, cases of type 2 diabetes. Physical inactivity and/or deficiencies of specific nutrients may also be involved (2). Obesity appears to play no role in type 1 diabetes pathogenesis (12).

3. ENVIRONMENTAL RISK FACTORS
Susceptibility to diabetes appears to be unmasked by a number of environmental factors acting on genetically susceptible individuals. They include (a) SEDENTARY LIFESTYLE: Sedentary life style appears to be an important risk factor for the development of type 2 diabetes. Lack of exercise may alter the interaction between insulin and its receptors and subsequently lead to type 2 diabetes. (b) (c) DEX: A high saturated fat intake has been associated with a higher risk of impaired glucose tolerance, and higher fasting glucose and insulin levels (6). Higher proportions of saturated fatty acids in serum lipids or muscle phospholipid have been associated with higher fasting insulin, lower insulin sensitivity and a higher risk of type 2 diabetes. Higher unsaturated fatty acids from vegetable sources and polyunsaturated fatty acids have been associated with reduced risk of type 2 diabetes and lower fasting and 2-hour glucose concentrations. Higher proportions of long-chain polyunsaturated fatty acids in skeletal muscle phospholipids have been associated with increased insulin sensitivity (6). In human intervention studies, replacement of saturated by unsaturated fatty acids leads to improved glucose tolerance and enhanced insulin sensitivity. However, long chain polyunsaturated fatty acids do not appear to confer additional benefit over monounsaturated fatty acids. When total fat intake is high (greater than 37 per cent of total energy), altering the quality of fat has no significant effect on diabetes risk (13). (d) DIETARY FIBRE: In many controlled experimental studies, high intakes of dietary fibre have been shown to result in reduced blood glucose and insulin levels in people with type 2 diabetes and improved glucose tolerance (14). Moreover an increased intake of whole-grain cereals, vegetables and fruits (all rich in NSP) was a feature of diets in randomized controlled trials. Thus the evidence for a potential protective effect of dietary fibre appears strong. A minimum daily intake of 20 grams of dietary fibre is recommended (6). Table 2 shows a summary of lifestyle and dietary factors associated with diabetes risk (MALNUTRITION): Malnutrition in early infancy and childhood may contribute to the risk of diabetes and impaired glucose tolerance in later life (15). 2. (e) ALCOHOL: Excessive intake of alcohol can increase the risk of diabetes by damaging the pancreas and by promoting obesity (16, 17). (f) VIRAL INFECTIONS: Among the viruses that have been implicated are rubella, mumps, and human coxsackie virus B4. Viral infections may trigger in immunogenetically susceptible people a sequence of events resulting in β-cell destruction. (g) CHEMICAL AGENTS: A number of chemical agents known to have toxic effects on beta cells, e.g., alkylating agents, the rodenticide VACOM, etc (15). A high intake of cyanide producing foods (e.g., cassava and certain beans) may also have toxic effects on β-cells. (h) STRESS: Surgery, trauma and stress of situations, internal or external, may "bring out" the disease. (i) OTHER FACTORS: High and low rates of diabetes have been linked to the number of social factors such as occupation, marital status, religion, socioeconomic status, urbanization and changes in life style which are elements of what is broadly known as social class. One of the most important epidemiological features of diabetes is that it is now common in the lower social classes whereas

50 years ago, the gradient was the reverse. One reason could be rapid changes in lifestyle in lower classes.

SCREENING FOR DIABETES

In the past, the commonest approach to diabetes screening was a preliminary, semi-quantitative test for glucose in a urine sample, followed by an oral glucose tolerance test for these found to have glycosuria. The underlying assumption is that early detection and effective control of hyperglycaemia in asymptomatic diabetics reduces morbidity.

1. Urine examination

Urine test for glucose, 2 hours after a meal, is commonly used in medical practice for detecting cases of diabetes. All those with glycosuria are considered diabetic unless otherwise proved by a standard oral glucose tolerance test. Most studies now confirm that although glucose is found in urine in the most severe cases of diabetes, it is often absent in milder forms of the disease, and such cases are likely to be missed by urine test. This is known as lack of “sensitivity.” To be more precise, the sensitivity of the test (i.e., proportion of people with diabetes who have a positive test) varies between 10-50 per cent. The lack of sensitivity means that many diabetics would have been missed if this had been the only test. That is, the test yields too many “false negatives.” Further, glycosuria may be found in perfectly normal people; this gives rise to “false-positives.” Since the specificity of the test is over 90 per cent, the yield of false-positives is not very high. For these reasons, urine testing is not considered an appropriate tool for case-finding or epidemiological surveys of the population (2).

2. Blood sugar testing

Because of the inadequacies of urine examination, “standard oral glucose test” remains the cornerstone of diagnosis of diabetes. Mass screening programmes have used glucose measurements of fasting, postprandial or random blood sample. The measurement of glucose levels in random blood samples is considered unsatisfactory for epidemiological use, at the most, it can give only a crude estimate of the frequency of diabetes in a population (2). The fasting value alone is considered less reliable since true fasting cannot be assured and spurious diagnosis of diabetes may more readily occur. Therefore, for epidemiological purposes, the 2-hour value after 75 g oral glucose may be used either alone or with the fasting value (2). Automated biochemistry has now made it possible to screen thousands of samples for glucose estimation. The criteria for the diagnosis of diabetes, proposed by WHO, are given in Table 3.

If 2-h plasma glucose is not measured, status is uncertain as diabetes or IGT cannot be excluded.

Source: (16)

Target population

Screening of the whole population for diabetes is not considered a rewarding exercise (17, 18). However, screening of “high-risk” groups is considered more appropriate. These groups are: (i) those in the age group 40 and over (ii) those with a family history of diabetes (iii) the obese (iv) women who have had a baby weighing more than 4.5 kg (or 3.5 kg in constitutionally small populations) (v) women who show excess weight gain during pregnancy, and (vi) patients with premature arteriosclerosis.

PREVENTION AND CARE

1. Primary prevention

Two strategies for primary prevention have been suggested: (a) population strategy, and (b) high-risk strategy (2).

a. POPULATION STRATEGY

The scope for primary prevention of type 1 diabetes is limited on the basis of current knowledge and is probably not appropriate (2). However, the development of prevention programmes for type 2 diabetes based on
elimination of environmental risk factors is possible. There is pressing need for primordial prevention—that is, prevention at the emergence of risk factors in countries in which they have not yet appeared. The preventive measures comprise maintenance of normal body weight through adoption of a healthy nutritional habit and physical exercise. The nutritional habits include an adequate protein intake, a high intake of dietary fibre and avoidance of sweet foods. Elimination of other less well defined factors such as protein deficiency and food toxins may be considered in some populations. These measures should be fully integrated into other community-based programmes for the prevention of non-communicable diseases (e.g., coronary heart disease).

b. HIGH-RISK STRATEGY

There is no special high-risk strategy for type 1 diabetes. At present, there is no practical justification for genetic counselling as a method of risk reduction. Since NIDDM appears to be linked with sedentary life-style, over-nutrition and obesity, correction of these may reduce the risk of diabetes and its complications. Since alcohol can indirectly increase the risk of diabetes, it should be avoided. Subjects at risk should avoid diabetogenic drugs such as oral contraceptives. It is wise to reduce factors that promote atherosclerosis, e.g., smoking, high blood pressure, elevated cholesterol and high triglyceride levels. These programmes may most effectively be directed at target population groups.

2. Secondary prevention

When diabetes is detected, it must be adequately treated. The aims of treatment are: (a) to maintain blood glucose levels as close as within the normal limits as is practicable (see Table 3); and (b) to maintain the body weight. Treatment is based on (a) diet alone—small balanced meals more frequently, (b) diet and oral antidiabetic drugs, or (c) diet and insulin. Good control of blood glucose projects against the development of complications. Please see in chapter 10 "Nutrition and health" under title "Nutritional factors in selected diseases" for details.

Proper management of the diabetic is most important to prevent complications. Routine checking of blood sugar, of urine for proteins and ketones, of blood pressure, visual acuity and weight should be done periodically. The feet should be examined for any defective blood circulation (Doppler, foot and leg probes are advised), loss of sensation and the health of the skin. Primary health care is of great importance to diabetic patients since most care is obtained at this level.

Glycosylated haemoglobin: There should be an estimation of glycated (glycosylated) haemoglobin at half-yearly intervals. This test provides a long-term index of glucose control. This test is based on the following rationale: glucose in the blood is complexed to a certain fraction of haemoglobin to an extent proportional to the blood glucose concentration. The percentage of such glycosylated haemoglobin reflects the mean blood glucose levels during the red cell life-time (i.e., about the previous 2–3 months) (19).

Self-care: A crucial element in secondary prevention is self-care. That is, the diabetic should take a major responsibility for his own care with medical guidance—e.g., adherence to diet and drug regimen, examination of his own urine and where possible blood-glucose monitoring; self-administration of insulin, abstinence from alcohol, maintenance of optimum weight, attending periodic check-ups, recognition of symptoms associated with glycosuria and hypoglycaemia, etc.

Table 4 shows some of the individual interventions in diabetes with evidence of efficacy.

*Home blood glucose monitoring: Assessment of control has been greatly aided by the recent facility of immediate, reasonably accurate, capillary blood glucose measurements either by one of the many meters now available or the direct reading Haemoglokinostat strips (20).

The patient should carry an identification card showing his name, address, telephone number (if any) and the details of the treatment he is receiving. In short, he must have a working knowledge of diabetes. All these mean education of patients and their families to optimize the effectiveness of primary health care services.

3. Tertiary prevention

Diabetes is major cause of disability through its complications, e.g., blindness, kidney failure, coronary thrombosis, gangrene of the lower extremities, etc. The main objective at the tertiary level is to organize specialist clinics (Diabetic clinics) and units capable of providing diagnostic and management skills of a high order. There is a great need to establish such clinics in large towns and cities (21). The tertiary level should also be involved in basic clinical and epidemiological research. It has also been recommended that local and national registries for diabetics should be established (2).

References

OBESITY

Obesity may be defined as an abnormal growth of the adipose tissue due to an enlargement of fat cell size (hypertrophic obesity) or an increase in fat cell number (hyperplastic obesity) or a combination of both (1). Obesity is often associated with other medical problems (2). See Table 1. Overweight is usually due to obesity but can arise from other causes such as abnormal muscle development and fluid retention (2). However, obese individuals differ not only in the amount of excess fat that they store, but also in the regional distribution of the fat within the body. The distribution of fat induced by the weight is associated with obesity, and the kind of disease that results. It is useful therefore, to be able to distinguish between those at increased risk as a result of "abdominal fat distribution" or "android obesity" from those with the less serious "gynoid" fat distribution, in which fat is more evenly and peripherally distributed around the body.

Prevalence

Obesity is perhaps the most prevalent form of malnutrition. As a chronic disease, prevalent in both developed and developing countries, and affecting children as well as adults, it is now so common that it is replacing the more traditional public health concerns including undernutrition. It is one of the most significant contributors to ill health. For industrialized countries, it has been suggested that such increase in body weight have been caused primarily by reduced levels of physical activity, rather than by changes in food intake or by other factors. It is extremely difficult to assess the size of the problem and compare the prevalence rates in different countries as no exact figures are available and also because the definitions of obesity are not standardized.

For easy reference and calculation of BMI values corresponding to recommended cut-offs, first find the height of the individual in the left hand column. The figures given in the row for that height correspond to various recommended cut-off values for adult BMI. Weight for two normal BMI values are also included.

Source: (6)

Overweight and obesity are the fifth leading risk of global deaths. Worldwide, obesity has more than doubled since 1980. In 2008, more than 1.4 billion adults, 20 years and older, were overweight. Of these over 200 million men and nearly 300 million women were obese (3).

In 2012, more than 40 million children under 5 years of age were overweight. Once considered a high-income country problem, overweight and obesity are now rising in low-and middle-income countries, particularly in urban settings. Close to 30 million overweight children are living in developing and 10 million in developed countries (3). Childhood obesity is associated with a higher chance of obesity, premature death and disability in adulthood. In addition, it is associated with future risk of increased breathing difficulties, increased risk of fractures, hypertension, early markers of cardiovascular disease, insulin resistance and psychological effects.

At least 3.4 million adults die each year as a result of being overweight or obese. In addition, 44 per cent of the diabetes burden, 25 per cent of ischaemic heart disease burden and between 7 to 41 per cent of certain cancer
burden is attributable to overweight and obesity (3). Overweight and obesity are linked to more deaths worldwide than underweight.

In India, the non-communicable risk factor survey phase 2 was carried out in the year 2007-2008, in the states of Andhra Pradesh, Kerala, Madhya Pradesh, Maharashtra, Tamil Nadu, Uttar Pradesh and Mizo. The survey showed high prevalence of overweight in all age groups except in 15–24 years group. Overweight prevalence was higher among females than males and in urban areas than in rural areas in 2007-2008 (8). It is important to note that in developing countries, these prevalence rates are expected to rise in the coming years due to changes in lifestyle choices, including increased consumption of high-fat and high-sugar foods. This highlights the importance of implementing targeted public health interventions to address the rising burden of overweight and obesity.

Epidemiological determinants

The etiology of obesity is complex, and it is one of the leading causes of global mortality and morbidity. Several factors contribute to the development of obesity, including genetic, environmental, and lifestyle factors.

(a) AGE: Obesity occurs at any age, and it becomes more common with age. Infants with excessive weight gain have an increased incidence of obesity in later life (9). About one-third of obese adults have been so since childhood (10). It has been well established that most adipose cells are formed early in life and the obese infant lays down more of these cells (hyperplastic obesity) than the normal infant. Hyperplastic obesity in adults is extremely difficult to treat with conventional methods.

(b) SEX: Women generally have higher rates of obesity than men, although men may have higher rates of overweight in the Framingham, USA study, men were found to gain more weight between the ages of 29 and 35 years, while women gain most between 45 and 49 years of age (10), i.e. at menopausal age. It has been claimed that women’s BMI increases with successive pregnancies. The recent evidence suggested that this increase is likely to be, on average, about 1.2 kg per pregnancy. On the other hand, in many developing countries, consecutive pregnancies at short intervals are often associated with weight loss rather than weight gain (8).

(c) GENETIC FACTORS: There is a genetic component in the etiology of obesity. Twin studies have shown a close correlation between the weights of identical twins even when they are reared in dissimilar environments (11). The profile of fat distribution is also characterized by a significant heritability level of the order of about 50 percent of the total human variation. Recent studies have shown that the amount of abdominal fat was influenced by a genetic component accounting for 50–60 percent of the individual differences (8).

(d) PHYSICAL INACTIVITY: There is convincing evidence that regular physical activity is protective against unhealthy weight gain. Where as sedentary lifestyle particularly sedentary occupation and inactivity recreation such as watching television promote it, physical activity and physical fitness are important modifiers of mortality and morbidity related to overweight and obesity (12). In some individuals a major reduction in activity without the compensatory decrease in habitual energy intake may be the major cause of increased obesity, e.g. in athletes when they retire and in young people who sustain injuries etc. Physical inactivity may cause obesity, which in turn restricts activity. This is a vicious circle. It is the reduced energy output that is probably more important in the etiology of obesity than used to be thought (11).

(e) SOCIO-ECONOMIC STATUS: The relationship of obesity to social class has been studied in some detail. There is a clear inverse relationship between socio-economic status and obesity. In some affluent countries, however, obesity has been found to be more prevalent in the lower socio-economic groups.

(f) EATING HABITS: Eating habits (e.g., eating in between meals, preference to sweets, refined foods and fats) are established very early in life. The composition of the diet, the periodicity with which it is eaten and the amount of energy derived from it are all relevant to the etiology of obesity. A diet containing more energy that needed may lead to prolonged post-prandial hyperinsulinemia and to deposition of triglycerides in the adipose tissue resulting in obesity (13). Nowadays television and print media is playing an important role in producing obesity by heavy advertisement of fast food outlets of energy-dense, micronutrient poor food and beverages (usually classified under the "not least" category in diet guidelines) of multinational corporations, which influence the daily eating habits. The consumer demand by itself may be influenced by advertising, marketing, culture, fashion and convenience (8). It has been calculated that a child whose energy requirement is 2000 kcal/day and who consumes 100 kcal/day extra will gain about 5 kg a year (10). The accumulation of one kilo of fat corresponds to 7,700 kcal of energy (14).

(g) PSYCHO SOCIAL FACTORS: Psychological factors (e.g., emotional disturbances) are deeply involved in the etiology of obesity. Overeating may be a symptom of depression, anxiety, frustration and loneliness in childhood as it is in adult life. Excessively obese individuals are usually withdrawn, self-conscious, lonely and secret eaters. An insight into the circumstances in which the obesity has developed is essential for planning the most suitable management.

(h) FAMILIAL TENDENCY: Obesity frequently runs in families (obese parent often has obese children), but this is not necessarily explained solely by the influence of genes.

(i) ENDOCRINE FACTORS: These may be involved in occasional cases, e.g. Cushing’s syndrome, growth hormone deficiency.

(j) ALCOHOL: A recent review of studies concluded that the relationship between alcohol consumption and adiposity was generally positive for men and negative for women (6).

(k) EDUCATION: In most affluent societies, there is an inverse relationship between educational level and prevalence of overweight (6).

(l) SMOKING: Reports that the use of tobacco lowers
Body weight began to appear more than 100 years ago, but detailed studies have been reported only during the past 10 years or so. In most populations, smokers weigh somewhat less than ex-smokers; individuals who have never smoked fell somewhat between the two.

**ETHNICITY**: Ethnic groups in many industrialized countries appear to be especially susceptible to the development of obesity and its complications. Evidence suggests that this may be due to a genetic predisposition to obesity that only become apparent when such groups are exposed to a more affluent lifestyle (9).

**(n)** **BMI USE**: Use of certain drugs, e.g., cortico-steroids, contraceptives, insulin, β-adrenergic blockers, etc. can promote weight gain (5).

**Use of BMI to classify obesity**

Body mass index (BMI) is a simple index of weight-for-height that is commonly used to classify underweight, overweight and obesity in adults. It is defined as the weight in kilograms divided by the square of the height in metres (kg/m²).

For example, an adult who weighs 70 kg and whose height is 1.75 m will have a BMI of 23.9:

\[ \text{BMI} = \frac{70 \text{ kg}}{1.75 \text{ m}^2} = 22.9 \]

The classification of overweight and obesity, according to BMI, is shown in Table 2. Obesity is classified as a BMI ≥ 30.0. The classification shown is in agreement with that recommended by WHO (12), but includes an additional subdivision at BMI 30.0-39.9 in recognition of the fact that management options for dealing with obesity differ above a BMI of 35. The WHO classification is based primarily on the association between BMI and mortality.

Source: (12)

These BMI values are age-independent and the same for both sexes. The table shows a simplistic relationship between BMI and the risk of comorbidity, which can be affected by a range of factors, including the nature of the diet, ethnic group and activity level. The risks associated with increasing BMI are continuous and graded and begin at a BMI above 25.

Although it can generally be assumed that individuals with a BMI of 30 or above have an excess fat mass in their body, BMI does not distinguish between weight associated with muscle and weight associated with fat. As a result, the relationship between BMI and body fat content varies according to body build and proportion, and it has been shown repeatedly that a given BMI may not correspond to the same degree of fatness across populations. Polynesians, for example, tend to have a lower fat percentage than Caucasian Australians at an identical BMI. In addition, the percentage of body fat mass increases with age up to 60-65 years in both sexes, and is higher in women than in men of equivalent BMI. In cross-sectional comparisons, therefore, BMI could be interpreted with caution if estimates of body-fat are required.

**INTRA-ABDOMINAL (CENTRAL) FAT ACCUMULATION AND INCREASED RISK**

Compared with subcutaneous adipose tissue, intra-abdominal adipose tissue has more cells per unit mass, higher blood flow, more glucocorticoid (cortisol) receptors, probably more androgen (testosterone) receptors, and greater catecholamine-induced lipolysis. These differences make intra-abdominal adipose tissue more susceptible to both normal stimulation and changes in lipid accumulation and metabolism. Furthermore, intra-abdominal adipocytokines are located upstream from liver in the portal circulation. This means that there is a marked increase in the flux of nonesterified fatty acid to the liver via the portal blood in patients with abdominal obesity.

There is good evidence that abdominal obesity is important in the development of insulin resistance, and in the metabolic syndrome (hyperinsulinemia, dyslipidemia, glucose intolerance, and hypertension) that link obesity with CHD (8). Premenopausal women have quantitatively more 'lipoprotein lipase' (LPL) and higher LPL activity in the gynæal and femoral subcutaneous regions, which contain fat cells larger than those in men, but these differences disappear after menopause (8).

**Assessment of obesity**

Before we consider assessment of obesity, it will be useful to first look at body composition as under:

- **the active mass** (muscle, liver, heart, etc.)
- **the fatty mass** (fat)
- **the extracellular fluid** (blood, lymph, etc.)
- **the connective tissue** (skin, bone, connective tissue)

Structurally speaking, the state of obesity is characterized by an increase in the fatty mass at the expense of the other parts of the body. The water content of the body is never increased in case of obesity.

Although obesity can easily be identified at first sight, a precise assessment requires measurements and reference standards. The most widely used criteria are:

1. **BODY WEIGHT**

   - Body weight, though not an accurate measure of excess
     fat, is a widely used index. In epidemiological studies it is
     conventional to accept ± 2 SD (standard deviations) from
     the mean weight for height as a cut-off point for obesity.
   - For adults, some people calculate various other indicators
     such as (10):
       - **Body mass index (Quetelet’s index)**: Weight (kg)
       - Height² (m)
       - **Ponderal index**: Weight (kg)
       - Height (cm)
       - Cube root of body weight (kg)
Broca index

\[
\text{Height (cm) minus 100}
\]

For example, if a person's height is 160 cm, their Broca index is 160 - 100 = 60 kg

Lorette's formula

\[
\text{Ht (cm) - 150}
\]

Corrected weight

\[
\begin{align*}
\text{Desirable weight} &= \frac{\text{Actual weight}}{2 \text{ (women) or 4 (men)}} \\
\text{This should not exceed 1.2}
\end{align*}
\]

The body mass index (BMI) and the Broca index are widely used. A FAO/WHO/UNU Report gives the much needed reference tables for body mass index (see Table 1) which can be used internationally as reference standards for assessing the prevalence of obesity in a community.

2. SKINFOLD THICKNESS

A large proportion of total body fat is located just under the skin. Since it is most accessible, the method most used is the measurement of skinfold thickness. A rapid and "non-invasive" method for assessing body fat. Several varieties of calipers (e.g., Harpenden skin calipers) are available for the purpose. The measurement may be taken at all the four sites - mid-triceps, biceps, subscapular and suprailiac regions. The sum of the measurements should be less than 40 mm in boys and 50 mm in girls (15). Unfortunately, standards for subcutaneous fat do not exist for comparison. Further, in extreme obesity, measurements may be impossible. The main drawback of skinfold measurements is their poor repeatability.

3. WAIST CIRCUMFERENCE AND WAIST : HIP RATIO (WHR)

Waist circumference is measured at the mid point between the lower border of the rib cage and the iliac crest. It is a convenient and simple measurement that is unrelated to height, correlates closely with BMI and WHR and is an approximate index of intra-abdominal fat mass and total body fat. Changes in waist circumference reflect changes in risk factors for cardiovascular disease and other forms of chronic diseases, and an increased risk of metabolic complications in men with waist circumference > 102 cm, and women with a waist circumference > 88 cm (12).

Over the past 10 years or so, it has become accepted that a high WHR (> 1.0 in men and > 0.85 in women) indicates abdominal fat accumulation.

4. OTHERS

In addition to the above, three well-established and more accurate measurements are used for the estimation of body fat. They are measurement of skin body water, total body potassium and of body density. The techniques involved are relatively complex and cannot be used for routine clinical purposes or for epidemiological studies (9). The introduction of measuring fat cells has opened up a new field in obesity research.

Hazards of obesity

Obesity is a health hazard and a detriment to well-being which is reflected in an increased morbidity and mortality: (a) INCREASED MORTALITY: Obesity is a positive risk factor in the development of hypertension, diabetes, gall bladder disease and coronary heart disease and certain types of cancers, especially the hormonally related and large bowel cancers. There are in addition, several associated diseases, which, although not usually fatal, cause a great deal of morbidity in the community, e.g., varicose veins, abdominal hernia, osteoarthritis of the knees, hips and lumbar spine, flat feet and psychological stress particularly during adolescence. Obese persons are exposed to increased risk from surgery. Obesity may lead to lowered fertility. Table 3 shows the relative risk of health problems associated with obesity. (b) INCREASED MORTALITY - The Framingham Heart Study in United States showed a dramatic increase in sudden death among men more than 20 per cent overweight as compared with those with normal weight. The increased mortality is brought about mainly by the increased incidence of hypertension and coronary heart disease. There is also an excess number of deaths from renal diseases. Obesity lowers life expectancy. More information is needed about the relationship between different degrees of obesity and morbidity and mortality. Please see in chapter 10 under "Nutritional factors in selected diseases" for dietary factors of obesity.

Prevention and control

Weight control is widely defined as approaches to maintaining weight within the "healthy" (i.e., "normal" or "acceptable") range of body mass index of 18.5 to 24.9 kg/m² throughout adulthood (WHO Expert Committee, 1995). It should also include prevention of weight gain of more than 5 kg in all people. In those who are already overweight, a reduction of 5–10 per cent of body weight is recommended as an initial goal (7).

Prevention of obesity should begin in early childhood. Obesity is harder to treat in adults than in children. The control of obesity centres around weight reduction. This can be achieved by dietary changes, increased physical activity and a combination of both. (a) DIETARY CHANGES: The following dietary principles apply both to prevention and treatment: the proportion of energy-dense foods such as simple carbohydrates and fats should be reduced; the fibre content of the diet increased, and fats, especially saturated fats, reduced and replaced by vegetable fats.
content in the diet should be increased through the consumption of common un-refined foods; adequate levels of essential nutrients in the low energy diets most conventional diets for weight reduction are based on 1000 kcal daily model for an adult) should be ensured, and reducing diets should be as close as possible to existing nutritional patterns (16). The most basic consideration is that the food energy intake should not be greater than what is necessary for energy expenditure. It requires modification of the patient’s behaviour and strong motivation to lose weight and maintain ideal weight. Unfortunately, most attempts to reduce weight in obese persons by dietary advice remain unsuccessful. (b) INCREASED PHYSICAL ACTIVITY. This is an important part of weight reduction programme. Regular physical exercise is the key to an increased energy expenditure. (c) OTHERS: Appetite suppressing drugs have been tried in the control of obesity. They are generally inadequate to produce massive weight loss in severely obese patients. Surgical treatment (e.g., gastric bypass, gastropexy, jaw-wiring, to eliminate the eating of solid food have all been tried with limited success (17). In short, one should not expect quick or even tangible results in all cases from obesity prevention programmes. Schools health education has an important role to play in teaching the people how to reduce overweight and prevent obesity. A truthful approach will be to identify those children who are at risk of becoming obese and find way of preventing it.

**VISUAL IMPAIRMENT AND BLINDNESS**

A compilation published by WHO in, 1966 (1) lists 65 definitions of blindness. As might be expected the definitions differed widely. Terms such as total blindness, economic blindness, and social blindness were in vogue. The 25th World Health Assembly in 1972 noted the complexity of the problem and considered the need for a generally accepted definition of blindness and visual impairment for national and international comparability. Taking into consideration existing definitions, the WHO proposed a uniform criterion and defined blindness as "visual acuity of less than 3/60 (Snellen) or its equivalent" (2). The current WHO International Classification of Diseases (ICD–10) describes the levels of visual impairment as shown in Table 1.

**The problem**

WORLD

In 2010, an estimated 285 million people worldwide were visually disabled, of whom nearly 39 million were blind and 246 million were with low vision, about 90 per cent of them living in developing countries. About 80 per cent of blindness is avoidable (treatable or potentially preventable). However, a large proportion of those affected remain blind for want of access to affordable eye care. Blindness leads not only to reduced economic and social status but may also result in premature death. The major causes of blindness and their estimated prevalence are cataract (33 per cent), glaucoma (2 per cent), and uncorrected refractive errors (myopia, hyperopia or astigmatism (43 per cent) (3). The number of people visually impaired from infectious diseases has greatly reduced in the last 20 years. About 82 per cent of all people who are visually impaired are aged 50 years and older, while this age group comprises about 20 per cent of the world’s population. With an increasing elderly population in many countries, more people will be at risk of age-related visual impairment. An estimated 19 million children are visually impaired. Of these, 12 million children are visually impaired due to refractive errors, a condition that could be easily diagnosed and corrected. 1.4 million are irreversibly blind for the rest of their lives (3).

Overall, visual impairment worldwide has decreased since the early 1990s. This decrease is principally the result of a reduction of visual impairment from infectious diseases through public health action.
INDIA

The estimated prevalence of blindness in India for the year 2004 was about 11.2 per 1000 population, of this 0.1 per 1000 population was among age group 0–14 years, 0.6 in age group 15–49 years, and 77.3 in 50 + years age group. In men the prevalence was 10.2 per 1000 population and in women 12.2 per 1000 population (4). According to rapid national survey on blindness 2006–07, the prevalence rate reduced from 3.1 per cent to 1.0 per cent and estimated national prevalence of childhood blindness/low vision was 0.8 per 1000 (5).

Causes of blindness

WORLD

The most frequent causes of blindness in developed countries are cataract, glaucoma, diabetes, vascular diseases (hypertension), cataract and degeneration of ocular tissues especially of the retina, and hereditary conditions.

In South-East Asia Region, cataract is the single most common cause of blindness being responsible for 50–80 per cent of all blindness. Uncorrected refractive errors are being increasingly recognized as a cause of blindness and low vision. Vitamin A deficiency, which has been responsible for most childhood blindness in the Region is gradually declining. The emerging causes of blindness include glaucoma, age-related macular degeneration, diabetic retinopathy, corneal ulcer and ocular trauma (6).

Among the leading causes of childhood blindness in the region are xerophthalmia, congenital cataract, congenital glaucoma and optic atrophy due to meningitis, retinopathy of prematurity, and uncorrected refractive errors. Xerophthalmia is largely under control with vitamin A distribution in immunization programmes.

There are an estimated 3–4 million persons blind, due to corneal opacity. With declining incidence of trachoma and xerophthalmia, the consequences of ocular trauma and corneal ulceration are emerging as important causes. According to an estimate, 6.5 million people are affected with, and 1.3 million eyes become blind due to corneal ulcer every year in the Region. (6). Trachoma remains an important cause in pockets in some countries although its importance as a cause of blindness has declined over the Years (7).

INDIA

The National Survey on Blindness 2006–07 conducted in the country recognized the main causes responsible for visual impairment and blindness. As shown in Table 3, the principal cause of blindness in India today is cataract, responsible for about 62.6 per cent of all cases. Cataract occurs more frequently with advancing age. Similarly cataract occurs a decade earlier in India relative to Europe and America. Uncorrected refractive error are responsible for about 19.7 per cent of blindness; overall prevalence of glaucoma was about 5.8 per cent; posterior segment pathology accounts for about 4.7 per cent cases (5). In a camp based study, glaucoma prevalence was found to be about 3.07 per cent with a slightly female preponderance (males 2.9 per cent and females 3.2 per cent). Primary open angle glaucoma was more common (about 1.7 per cent) than primary angle closure glaucoma (0.73 per cent) (8). In the others groups, injuries at a cause of blindness accounts for 1.2 per cent (9). There is evidence that injuries are on the increase due to increase in cottage industry (e.g. carpentry, blacksmith, stoner crushing, chiselling and hammering and chopping wood), and rapid industrialization in the country. The other cases in this group includes congenital disorder, uveitis, retina detachment, tumours, diabetes, hypertension. diseases of the nervous system, leprosy.

Retinopathy of prematurity (ROP) is emerging as an important cause of childhood blindness. With the advent of better neonatal care, and increasing age of prime and government NICUs, the survival of the premature babies (born before 30 weeks of gestation and 1500 grams of birth weight) has increased. ROP can occur in all babies at risk of developing ROP and there is dire necessity to create awareness not only in public but also amongst neonatologists and paediatricians to detect and treat ROP in time.

Epidemiological determinants

(a) AGE: About 30 per cent of the blind in India are said to lose their sight before they reach the age of 20 years, and many under the age of 5 years. Refractive error, trachoma, conjunctivitis and malnutrition (vitamin A deficiency) are important causes of blindness among children and the younger age groups; cataract, refractive error, glaucoma and diabetes are causes of blindness in middle age; accidents and injuries can occur in all age groups, but more importantly in the age group 20 to 40 years. (b) SEX: A higher prevalence of blindness is reported in females than in males in India. This has been attributed to a higher prevalence of trachoma, conjunctivitis and cataract among females than in males (10). (c) MALNUTRITION: Malnutrition as a cause of blindness was hardly recognized a few years ago. It is closely related not only with low vitamin A intake, but also with infectious diseases of childhood especially measles and diarrhoea (which precipitate malnutrition). In many cases protein energy malnutrition (PEM) is also associated with blindness. Severe blinding corneal destruction due to vitamin A deficiency (e.g. keratomalacia) is largely limited to the first 4–6 years of life and is especially frequent among those 6 months to 3 years of life. (d) OCCUPATION: It has long been recognized that people working in factories, workshops and cottage industries are prone to eye injuries because of exposure to dust, airborne particles, flying objects, gases, fumes, radiation (usually welding flash), electrical flash, etc. Many workers including doctors are known to have developed premature cataracts while exposed to X-rays, ultraviolet rays or heat waves (e) SOCIAL CLASS: There is a close relationship between the incidence of blindness and socio-economic status. Surveys indicate that blindness is twice more prevalent in the poorer classes than in the
1. INITIAL ASSESSMENT
The first step is to assess the magnitude, geographic distribution and causes of blindness within the country or region by prevalence surveys. This knowledge is essential for setting priorities and development of appropriate intervention programmes.

2. METHODS OF INTERVENTION (15)
(a) Primary eye care
A wide range of eye conditions (e.g., acute conjunctivitis, ophthalmia neonatorum, trachoma, superficial foreign bodies, xerophthalmia) can be treated without the need for air support at the grass-root level by locally trained primary health workers (e.g., village health guides, multi-purpose workers) who are the first to make contact with the community. For this purpose, they are provided with essential drugs such as topical tetracycline, vitamin A capsules, eye bandages, shields, etc. They are also trained to offer difficult cases (e.g., corneal ulcers, penetrating foreign bodies, painful eye conditions and infections which do not respond to treatment) to the nearest PHC or district hospital. Their activities also involve promotion of personal hygiene, sanitation, good dietary habits and safety in general. Currently, there is one village health guide for 1000 population and 2 multipurpose workers for 5000 population in India.

In short, primary eye care is based firmly in primary health care which is "...essential health care....made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford..." (Article VI of the Declaration of Alma-Ata, 1978).

(b) Secondary care
Secondary care involves definitive management of common blinding conditions such as cataract, trichiasis, entropion, ocular trachoma, glaucoma, etc. This care is provided in PHCs and district hospitals where eye departments or eye clinics are established. The secondary care may involve the use of mobile eye clinics. For instance, cataract accounts for over 62 per cent of blindness in India. The eye camp approach to make cataract surgery available has been highly successful, and has received wide popular support. Apart from cataract operations, these camps undertake general health surveys for the early detection of visual defects as well as educator of the masses. For mobile services to be effective, there must be good community participation in the programme. Adequate follow-up and evaluation must also be provided. The "mobile units", therefore, provide a means of linking facilities and benefits to the people as part of a comprehensive strategy for eye care. The great advantage of this strategy is, it is problem-specific and makes the best use of local resources and provides necessary eye care to the population at the peripheral level (13).

(c) Tertiary care
These services are usually established in the national or regional capitals and are often associated with Medical Colleges and Institutes of Medicine. They provide sophisticated eye care such as retinal detachment surgery, corneal grafting and other complex forms of management not available in secondary centres. The majority of States in India has passed the Corneal Grafting Acts which have helped the establishment of Eye Banks. Other measures of rehabilitation comprise education of the blind in special...
accidents and injuries

an accident has been defined as: "an unexpected, unplanned occurrence which may involve injury" (1). a who advisory group in 1956 defined accident as an
"unmediated event resulting in recognizable damage" (2). According to another definition, an accident is that "sequence in a sequence of events which usually produces unintended injury, death or property damage".

Accidents represent a major epidemic of non-communicable disease in the present century. They are no longer considered accidental. They are part of the price we pay for technological progress.

Accidents have their own natural history and follow the same epidemiological pattern as any other disease — that is, the agent, the host and the environment interacting together to produce injury or damage. They occur more frequently in certain age-groups, at certain times of day and week and at certain localities. Some people are more prone to accidents than others and susceptibility is increased by the effect of alcohol and other drugs as well as physiological state such as fatigue. Lastly, a majority of accidents are preventable.

Measurement of the problem

a. MORTALITY

The following epidemiological indices will be useful in assessing the magnitude of the problem: (i) Proportional mortality rate: That is, the number of deaths due to accidents per 100 (or 1000) total deaths. (ii) Number of deaths per million population: The term "killed" (in a road traffic accident) is defined as any person who was killed outright or who died within 30 days as a result of the accident (3). (iii) Death rate per 1000 (or 100,000) registered vehicles per year. (iv) Number of accidents or fatalities per 1000 kilometres or passengers per kilometre. (v) Deaths of vehicle occupants per 1000 vehicles per year, etc.

b. MORBIDITY

Morbidity is measured in terms of "serious injuries" and "slight injuries" (4). The seriousness of the injury is assessed by a scale known as "Abbreviated Injury Scale" (3). Morbidity rates are generally less reliable because of under-reporting and mis-reporting.

c. DISABILITY

An important outcome of the accident process is disability, which may be temporary or permanent, partial or total. Measurement of disability in terms of its duration is a limited concept; it does not take into consideration the psychological or social aspects of an accident or injury (5). The international classification of impairments, disabilities and handicaps is an attempt by WHO (6) to estimate the disability of individuals at a given moment.

The problem

WORLD

Injuries constitute a variable epidemic. During 2008 road traffic injuries ranked fourth among the leading causes of deaths in the world. Injuries are responsible for approximately 9 per cent (about 5.12 million) of all causes of deaths in the world and about 16 per cent of the disabilities are reported due to injuries. They are also the major cause of death among persons aged 10–24 years. In the developed regions, 57 per cent of male deaths and 63 per cent of female deaths in this age group are due to injuries, mainly traffic accidents. The main causes of injuries worldwide and their percentages are shown in Table 1. About 3.6 million people die of unintentional injuries and about 1.5 million die of intentional injuries. Road traffic accidents claim 1.2 million lives, self-inflicted injuries and violence are becoming important causes of loss of lives.

INDIA

Accidents are definitely on an increase in India. Increasing mechanization in agriculture and industry, induction of semi-skilled and unskilled workers in various operations and rapid increase in vehicular traffic have resulted in an increase in morbidity and mortality due to accidents. Overcrowding, lack of awareness and poor implementation of essential safety precautions result in an increasing number of accidents. Consumption of poisonous substances accidentally or intentionally is also on the rise. Deaths, disabilities and hospitalization due to injuries continue to have impact of socio-economic loss to individuals, families, society and infrastructure. The traditional view of injury as an accident, has resulted in the neglect of this aspect of public health. Today injuries are low in priority for policy makers, and only few plans are drawn for injury prevention.

Table 2 shows the reported number of accidental deaths by main causes in India.

TYPES OF ACCIDENTS

1. Road traffic accidents

In many countries, motor vehicle accidents rank first among all fatal accidents. Every year almost 1.24 million people die from road accidents in the world. In addition, for every death, there are as many as 20–50 non-fatal injuries and 10–20 serious injuries requiring long periods of expensive care, nursing and treatment. Road traffic fatalities rate is higher in younger age groups. Children and young people under the age of 25 years account for over 30 per cent of those killed and injured in road accidents.

From a young age, males are more likely to be involved in road traffic crashes than females. Among young drivers, males under the age of 25 years are almost 3 times as likely to be killed in a car crash as young females (9).

Nearly half (46 per cent) of those dying on roads are vulnerable road users like pedestrians, cyclists and

Source: (8)

motorcyclists. Compared to cars, the two-wheelers are unstable and provide little protection for their riders in accidents. In developed countries, four wheelers are more frequently involved in accidents.

More than 90 per cent deaths that result from road traffic accidents occur in low and middle-income countries. Even within high-income countries, people from lower socio-economic backgrounds are more likely to be involved in road traffic accidents (9).

**INDIA**

During the year 2011, a total of 4.43 lac road traffic accidents were reported in the country. The rate of death per 1000 vehicles has decreased from 1.6 in 2007 to 1.2 in 2011. The rate of accidental deaths per 1000 vehicles was highest in Bihar and Sikkim at 1.6, followed by West Bengal at 1.5 (10).

24.9 per cent of victims of road traffic accidents were occupants of two wheelers. Maximum number of road accidents were reported in the month of May (65,064) followed by January (39,185).

**Risk factors (9)**

**Speed**

An increase in average speed is directly related both to the likelihood of a crash occurring and to the severity of the consequences of the crash. Some other facts are as below:

- Pedestrians have a 90% chance of surviving a car crash at 30 km/h or below, but less than a 50% chance of surviving an impact of 45 km/h or above.
- 30 km/h speed ones can reduce the risk of a crash and are recommended in areas where vulnerable road users are common (e.g. residential areas, around schools).
- Apart from reducing road traffic injuries, lower average traffic speeds can have other positive effects on health outcomes (e.g. by reducing respiratory problems associated with car emissions).

**Drink-driving**

Drinking and driving increases both the risk of a crash and the likelihood that death or serious injury will result.

- The risk of being involved in a crash increases significantly above a blood alcohol concentration (BAC) of 0.04 g/dl.
- Laws that establish BACs of 0.05 g/dl or below are effective at reducing the number of alcohol-related crashes.
- Enforcing sobriety check-points and random breath testing can lead to reductions in alcohol-related crashes by about 20%, and have shown to be very cost-effective.

**Motorcycle helmets**

- Wearing a motorcycle helmet correctly can reduce the risk of death by almost 40% and the risk of severe injury by over 70%.
- When motorcycle helmet laws are enforced effectively, helmet wearing rates can increase to over 90%.
- Requiring helmets to meet a recognized safety standard is important to ensure that helmets can effectively reduce the impact of a collision to the head in the event of a crash.

**Seat-belts and child restraints**

- Wearing car seat-belt reduces the risk of fatality among
Multiple causation
Accidents are a complex phenomena of multiple causation (Fig. 1). The aetiological factors may be classified into two broad categories - human and environmental. Up to 90 per cent of the factors responsible for accidents are attributed to human failure. Many of the psychological circumstances in which accidents occur are still poorly known (5).

PREVENTION
Accidents don't just happen; they are caused. The causes in a given situation must be identified by epidemiological methods. Since accidents are multifactorial, they call for an intersectoral approach to both prevention and care of the injured. The various measures comprise the following:

1. Data collection
There should be a basic reporting system of all accidents. The national data should be supplemented by special surveys and in-depth studies. These studies will bring out the risk factors, the circumstances and chain of events leading up to the accident. These details are rarely provided by the basic reporting system. Detailed environmental data relating to the road, vehicle, weather, etc must also be collected. The police have a statutory duty in many countries to investigate accidents, for legal as well as preventive purposes; the data collecting systems should recognize this and take police records as their starting point (3). Without adequate data collection, analysis and interpretation there could be no effective counter-measures, evaluations and strategies for prevention.

2. Safety education
There is a widespread belief that accidents are inevitable; this fatalistic attitude must be curbed. Safety education must begin with school children. The drivers need to be trained in proper maintenance of vehicles and safe driving. Young people need to be educated regarding risk factors, traffic rules and safety precautions. They should also be trained in first aid. It has been aptly said that "If accident is a disease, education is its vaccine".

3. Promotion of safety measures
(a) Seat belts: The use of seat belts reduces the number of fatalities and non-fatal injuries by approximately 50 per cent. They should be made compulsory for cars, light trucks and similar vehicles (3). (b) Safety helmets: They reduce the risk of head injury by 30 per cent on an average and that of fatalities by 40 per cent (5). They prevent laceration of the scalp to a great extent. Recently, the full-face integral helmet has become very popular. (c) Children: Another safety measure is to ensure that children remain seated when they are in a vehicle. They should be prohibited to take the front seats of cars (5). A few countries have introduced laws which require that children of under 12-15 years in cars be in the rear seats only. (d) Others: These comprise use of door locks, proper vehicle design, use of laminated high-penetration resistance windshield glass, etc.

4. Alcohol and other drugs
Alcohol impairs driving ability and increases the risk of an accident as well as the severity of its consequences. Conclusions of surveys carried out in several countries have shown that alcohol is the direct cause of 30 to 50 per cent of severe road accidents.

**Primary factors in accidents**

**6. Elimination of causative factors**

The factors which tend to cause accidents must be sought out and eliminated, e.g., improvement of roads, imposition of speed limits and marking of danger points.

**7. Enforcement of laws**

Legislation embodies codified set of rules. These are enforced by the State to prevent accidents. These include driving tests, medical fitness to drive, enforcement of speed limits, compulsory wearing of seat-belts and crash-helmets, checking of blood alcohol concentration, road-side breath testing for alcohol, regular inspection of vehicles, periodic re-examination of drivers over the age of 55, etc.
8. Rehabilitation services

Rehabilitation consists of a number of elements which each injured person should benefit from. These are medical rehabilitation, social rehabilitation, occupational rehabilitation, etc. The aim of rehabilitation is to prevent, reduce or compensate disability and thereby handicap.

9. Accident research

The future of accident prevention is in research. Such research will be of great value if it provides knowledge about the extent, type and other characteristics of accidents, correlates accident experience with personal attributes and the environments in which accidents occur, investigates new and better methods of altering human behaviour; seeking ways to make environments safer; and evaluating more precisely the efficiency of control measures. This area is now termed accidentology.

2. Domestic accidents

By "domestic accident" is meant an accident which takes place in the home or in its immediate surroundings, and, more generally, all accidents not connected with traffic, vehicles or sport (16). The most frequent causes of domestic accidents are:

1. drowning
2. burns (by a flame, hot liquid, electricity, crackers or fire works, chemicals)
3. falls
4. poisoning (e.g., drugs, insecticides, rat poisons, kerosene)
5. injuries from sharp or pointed instruments
6. bites and other injuries from animals.

Drowning (12)

Drowning is the process of experiencing respiratory impairment from submersion/immersion in liquid.

Victims of drowning have a very slim chance of survival after immersion. The victim loses consciousness after about 2 minutes of immersion, and irreversible brain damage can take place after 4–6 minutes. Therefore, prevention strategies are very important.

In 2011, an estimated 359,000 people died from drowning, making drowning a major public health problem worldwide. Injuries account for nearly 19% of total global mortality. Drowning is the 3rd leading cause of unintentional injury death. It accounts for 7% of all injury-related deaths.

It is a common method of suicide. The global burden and death from drowning is found in all economies and regions, however; low and middle-income countries account for 95% of unintentional drowning deaths; over 50% of the world’s drowning occurs in the WHO Western Pacific Region and WHO South-East Asia Region; China and India have particularly high drowning mortality rates and together contribute 43% of the world’s drowning deaths and 41% of the total global DALYs (disability-adjusted life years) lost related to drowning.

There is a wide range of uncertainty around the estimate of global drowning deaths. It is important to point out that the global problem is much greater than the above figures reveal; due to the way data are classified, global numbers exclude drowning due to floods (catastrophes), boating and water transport mishaps. Non-fatal drowning statistics in many countries are not readily available or are unreliable.

Risk factors (12)

1. Age: Age is one of the major risk factors for drowning. This relationship is often associated with a lapse in supervision. In general, children under 5 years of age have the highest drowning mortality rates worldwide. Canada and New Zealand are the only exceptions, where adult males drown more frequently.

2. Gender: Males are especially at risk of drowning with twice the overall mortality rate of females. They are more likely to be hospitalized than females for non-fatal drowning. Studies suggest that the higher drowning rates among males are due to increased exposure to water and riskier behaviour such as swimming alone, drinking alcohol before swimming alone, and boating.

3. Access to water: Increased access to water is another risk factor for drowning. Individuals with occupations such as commercial fishing or fishing for subsistence, using small boats in low-income countries, are more prone to drowning. Children who live near open water sources, such as ditches, ponds, irrigation channels, or pools are especially at risk.

4. Other risk factors: There are other factors that are associated with an increased risk of drowning, such as:
   a. infants left unsupervised or alone, or with another child in a bathtub;
   b. unsafe or overcrowded transportation vessels lacking flotation devices;
   c. alcohol use, near or in the water;
   d. medical conditions, such as epilepsy;
   e. tourists unfamiliar with local water risks and features; and
   f. floods and other cataclysmic events like tsunamis.

Prevention (12)

Drowning prevention strategies should be comprehensive and include: engineering methods which help to remove the hazard, legislation to enforce prevention and assure decreased exposure, education for individuals and communities to build awareness of risk and to act in response if a drowning occurs.

Engineering methods to eliminate exposure to water hazards are the most effective strategy for drowning prevention. Examples include:
- development and implementation of safe water systems, such as drainage systems, piped water systems, flood control embankments in flood prone areas;
- building four-sided pool fences or barriers preventing access to standing water;
- creating and maintaining safe water zones for recreation;
- covering of wells or open cisterns;
- emptying buckets and baths, and storing them upside down.

Laws or regulations which target risk factors for drowning include laws requiring regular safety checks of transportation vessels, and laws on alcohol use while boating or swimming.

Individual and community education on drowning awareness, learning water survival skills and ensuring the presence of lifeguards at swimming areas are promising strategies to prevent drowning.

Burns (13)

A burn is an injury to the skin or other organic tissue primarily caused by heat or to radiation, radioactivity.
electricity, friction or contact with chemicals. Thermal (heat) burns occur when some or all of the cells in the skin or other tissues are destroyed by:

- hot liquids (scalds)
- hot solids (contact burns), or
- flames (flame burns).

The problem
Burns are a global public health problem, accounting for an estimated 265,000 deaths annually. About 11 million people worldwide require medical attention due to severe burns. The majority of these occur in low and middle-income countries and almost half occur in the South-East Asia Region.

In many high-income countries, burn death rates have been decreasing, and the rate of child deaths from burns is currently over seven times higher in low and middle-income countries than in high-income countries.

Non-fatal burns are a leading cause of morbidity, including prolonged hospitalization, disfigurement and disability, often with resulting stigma and rejection.

It is estimated that over one million people are moderately or severely burnt every year in India. In Bangladesh 1.73 lac children get moderate or severe burns every year with about 17 per cent getting temporary disability and 18 per cent permanent disability. Burns are the second most common injury in rural Nepal, accounting for 5 per cent disabilities.

Risk factors (13)

Gender: Females suffer burns more frequently than males. Women in the South-East Asia Region have the highest rate of burns, accounting for 27% of global burn deaths and nearly 70% of burn deaths in the region. The high risk for females is associated with open fire cooking, or the use of old unsafe cookstoves, which can ignite loose clothing. Open flames used for heating and lighting also pose risks, and self-directed or interpersonal violence are also important factors (although understudied).

Age: Along with adult women, children are particularly vulnerable to burns. Burns are the 11th leading cause of death of children aged 1–9 years and are also the fifth most common cause of non-fatal childhood injuries. While a major risk is improper adult supervision, a considerable number of burn injuries in children result from child maltreatment.

Socio-economic factors
People living in low and middle-income countries are at higher risk for burns than people living in high-income countries. Within the countries also, burn risk correlates with socio-economic status.

Other risk factors
There are a number of other risk factors for burns, including:

- occupations that increase exposure to fire;
- poverty, overcrowding and lack of proper safety measures;
- placement of young girls in household roles such as cooking and care of small children;
- underlying medical conditions, including epilepsy, peripheral neuropathy, and physical and cognitive disabilities;
- alcohol abuse and smoking;
- easy access to chemicals used for assault (such as in acid violence attacks);
- use of kerosene (paraffin) as a fuel source for non-electric domestic appliances;
- inadequate safety measures for liquefied petroleum gas and electricity.

Burns occur mainly in the home and workplace. Community surveys in Bangladesh and Ethiopia showed that 80-90% of burns occur at home. Children and women usually get burns in domestic kitchens, from upset receptacles containing hot liquid, or flames, or from cookstove explosions. Men are more likely to get burns in the workplace due to fire, scalds, chemicals and electricity.

Prevention (13)

Burns are preventable. High-income countries have made considerable progress in lowering rates of burn deaths, through a combination of prevention strategies and improvements in the care of people affected by burns. Most of these advances in prevention and care have been incompletely applied in low and middle-income countries. Increased efforts to do so would likely lead to significant reduction in rates of burn-related death and disability.

Prevention strategies should address the hazards for specific burn injuries, education for vulnerable populations and training of communities in first-aid. An effective burn prevention plan should be multisectoral. There are a number of specific recommendations for individuals, communities and public health officials to reduce burn risk.

FIRST-AID (13)

Do's
1. Stop the burning process by removing clothing and irrigating the burn.
2. Use cool running water to reduce the temperature of the burn.
3. Extinguish flames by allowing the person to roll on the ground, or by applying a blanket, or by using water or other fire-extinguishing liquids.
4. In chemical burns, remove or dilute the chemical agent by irrigating with large volumes of water.
5. Wrap the patient in a clean cloth or sheet and transport to the nearest appropriate facility for medical care.

Don'ts
1. Do not start first-aid before ensuring your own safety (switch off electrical current, wear gloves for chemicals etc.)
2. Do not apply paste, oil, balmi (turmeric) or raw cotton to the burn.
3. Do not apply ice because it deepens the injury.
4. Avoid prolonged cooling with water because it may lead to hypothermia.
5. Do not open blisters until topical antimicrobials can be applied, by a health-care provider.
6. Do not apply any material directly to the wound as it might become infected.
7. Avoid application of topical medication until the patient has been placed under appropriate medical care.
Falls

Globally, falls are a major public health problem. An estimated 424,000 fatal falls occur each year, making it the second leading cause of unintentional injury death, after road traffic injuries. Though not fatal, 37.3 million falls are severe enough to require medical attention. Such falls are responsible for 17 million DALYs lost. Over 88% of fall-related fatalities occur in low and middle-income countries, with regions of the Western Pacific and South East Asia accounting for more than two-thirds of these deaths. In all regions of the world, death rates are highest among adults over the age of 60 years (14).

Falls are responsible for the largest number of hospital visits for non-fatal injuries, especially for children and young adults. Falls from rooftops, balconies, windows and stair cases are common. Factors specific to SEAR countries are falls from trees of workers picking fruits or coconuts, topping toddy, children falling from rooftops while flying kites, high incidence of falls among construction and forestry workers. As life expectancy increases in these countries, the incidence of hip and other fractures due to fall among the elderly are also assuming greater proportions (15).

Some of the risk factors include (14):
- occupations at elevated heights or other hazardous working conditions;
- alcohol or substance use;
- socio-economic factors including poverty, overcrowded housing, young maternal age;
- underlying medical conditions, such as neurological, cardiac or other disabling conditions;
- side-effects of medications, physical inactivity and loss of balance, particularly among older people;
- unsafe environments, particularly for those with poor balance and limited vision.

Prevention (14)

For children, effective interventions include multifaceted community programmes, engineering modifications of nursery furniture, playground equipment, and other products; and legislation for the use of window guard.

For older individuals, fall prevention programmes can include a number of components to identify and modify risk, such as:
- screening within living environments for risks for falls;
- clinical interventions to identify risk factors, such as medication review and modification, treatment of low blood pressure, Vitamin D and calcium supplementation, treatment of correctable visual impairment;
- home assessment and environmental modification for those with known risk factors or a history of falling;
- prescription of appropriate assistive devices to address physical and sensory impairments;
- muscle strengthening and balance retraining prescribed by a trained health professional.

Poisoning

Poisoning was responsible for an estimated 252,000 deaths during the year 2008 worldwide. In India about 28,012 poisoning deaths were reported during the year 2010 (7). The most common agents responsible for poisoning are pesticides, kerosene, prescription drugs, and household chemicals. Pesticides are widely used in many countries where agriculture is an important part of the economy. China, India, and Thailand indicate that common availability and use of toxic pesticides is responsible for intentional and unintentional poisoning.

In Sri Lanka, pesticides are one of the main agents used in attempted suicide in rural areas. The use of organophosphate insecticides in suicide attempts has been reported to be as high as 20-30% per cent. Periapical intoxication is known to cause irreversible damage in patients. Many countries also report dependence of ingestion of kerosene as a leading cause of poisoning, especially among children (15). A study from Thailand revealed that 54 per cent of cases of poisoning among pre-school children involved therapeutic drugs.

Snake bite

Snake bite is a neglected public health issue in many tropical and subtropical countries. About 5 million snake bite occur each year, resulting in up to 2.4 million envenomings (poisoning from snake bites) at least 94,000-125,000 deaths and around 400,000 amputations and other permanent disabilities. Most of these occur in Africa, Asia and Latin America. In Africa alone there are an estimated 1 million snake bite annually with about half needing treatment. This type of injury is often found among women, children and farmers in poor rural communities in low and middle-income countries (18).

The outcome of snake bite depends on numerous factors, including the species of snake, the area of the body bitten, the amount of venom injected, and the health condition of the victim. Feelings of terror and panic are common after a snake bite and can produce a characteristic set of symptoms mediated by the autonomic nervous system, such as tachycardia and nausea. Bites from non-venomous snakes can cause intense local pain due to inflammation caused by the snake's teeth, or from a resulting infection. A bite may also trigger an anaphylactic reaction, which is potentially fatal. Patients usually have no history of snake bites in the region, as effective treatment for bite inflicted by some species can be ineffective for others.

The venom of poisonous snakes may be predominantly neurotoxic or predominantly cytolytic. Neurotoxins cause respiratory paralysis and cytolytic venoms cause tissue destruction by digestion and haemorrhage due to haemolysis and destruction of the endothelial lining of the blood vessels. The manifestations of rattlesnake envenomation are mostly local pain, redness, swelling and extravasation of blood. Peripheral tingling, metallic taste, nausea, and vomiting, hypotension and coagulopathy may also occur. Neurotoxic envenomation may cause ptosis, dysphagia, diplopia, and respiratory failure. Venom emitted from some types of cobras, almost all vipers cause necrosis of muscle tissue. Muscle tissue begin to die throughout the body and it results in accumulation of myoglobin in the renal tubules which leads to acute renal failure.

Early clues that a patient has severe envenoming (19):
- Snake identified as a "very dangerous one."
- Rapid early extension of local swelling from the site of the bite.
- Early tender enlargement of local lymph nodes, indicating spread of venom in the lymphatic system.
- Early systemic symptoms: collapse (hypotension, shock), nausea, vomiting, diarrhea, severe headache, “heaviness” of the eyelids, inappropriate (pathological) drowsiness or early ptosis/ophthalmoplegia.
- Early spontaneous systemic bleeding.
- Passage of dark brown/black urine.

FIRST-AID
The Government of India developed a national snake-bite protocol in 2007 which includes following advice:
1. Reassure the patient. 70% of all snake bites are from non-venomous species. Only 50% of bites by venomous species actually envenomate the patient.
2. Immobilize in the same way as a fractured limb. Use bandages or cloth to hold the splints, not to block the blood supply or apply pressure. Do not apply any compression in the form of tight ligatures, they don’t do any good.
3. Do not give alcoholic beverages or stimulants. They are known vasodilators and they speed up the absorption of venom.
4. Remove any items or clothings which may constrict the bitten limb if it swells (rings, bracelets, watches, footwear, etc.).
5. Do not incise or manipulate the bitten site. Do not apply ice.
6. Transport the patient to a medical facility for definitive treatment.

ANTIVENOM (19)
Until the advent of antivenom, bites from some species of snake were almost universally fatal. Despite huge advances in emergency therapy, antivenom is often still the only effective treatment for envenomation. The first antivenom was developed in 1939 by French physician Albert Calmette for the treatment of Indian cobra bites. Antivenom is made by injecting a small amount of venom into an animal (usually a horse or sheep) to initiate an immune system response. The resulting antibodies are then harvested from the animal’s blood.

Antivenom is injected into the person intravenously, and works by binding to and neutralizing venom enzymes. It cannot undo damage already caused by venom, so antivenom treatment should be sought as soon as possible.

Modern antivenoms are usually polyvalent, making them effective against the venom of numerous snake species.

Pharmaceutical companies which produce antivenom target their products against the species native to a particular area. Although some people may develop serious adverse reactions to antivenom, such as anaphylaxis, in emergency situations this is usually treatable and hence the benefit outweighs the potential consequences of not using antivenom.

3. Industrial accidents
There are approximately 580 million workers in the South-East Asia Region. Approximately 60-80 per cent of these workers are employed in agriculture, fisheries, home industries, and small-scale units. Injuries due to these occupations result in an estimated 120 million injuries and 200,000 deaths per year (15).

Though reliable estimates for work related injuries and deaths in the Region are not available, partly because a majority of the workers are employed in unorganized sectors, few studies indicate that nearly one per cent of deaths and 15 per cent of permanent impairment result from agricultural injuries. Agriculture workers are exposed to wide variety of physical, chemical (pesticide and fertilizers), biological (animal bites and animal related injuries) and mechanical injuries. The estimates from agriculture injury vary from 22-29 per 1000 workers. The incidence rate of injury among agriculture workers in India is estimated to be 116 per 100,000 workers. In a study population of 23,000 in rural Haryana, nearly 31 per cent of the injuries were related to agricultural activity (17). Of these, serious injuries were caused by mechanized equipment and tractors (15).

Rapid industrialization has also resulted in mortality and morbidity of many workers in hazardous industries.

The unique features common to the workplace in this region are that the manual labour content is high and the man-machine interactions is unsafe. In addition, there is greater emphasis on attempts to change the worker’s behaviour, but design that provide automatic protection are ignored. Children and people who are challenged physically, as well as mentally are at a greater risk of encountering occupational injuries (15).

4. Railway accidents
With the increase in number of train and passengers, the increase in the number of accidents and casualties resulting therefrom is not unexpected. During 2010, about 30,576 people died of railway accidents in India. The main factors involved in railway accidents is human failure.

5. Violence
An estimated 1,510,000 persons died in 2008 due to violence or intentional injuries (homicide, suicide and war) worldwide, of which 420,000 were in SEAR countries (7). The accurate statistics are not available, as not all those injured go to the hospital or state that the injury is because of violence. Violence behind closed doors are grossly unreported.

Violence is reported to be increasing rapidly. It also follow the same epidemiological pattern as any other disease (host, agent and environment), i.e. a motivated person who injures; a suitable target; and a suitable environment or the absence of a guardian, all coinciding in time and space. Often, it may only be possible to initiate steps for prevention after an episode of violence has already taken place.

Some of the risk factors for violent behaviour are (15):
- Exposure to violence and societal acceptability of violence as a means to solve problems. The image of violence as an acceptable and effective tool for solving problems, whether across international borders, on the street, or around the home, may spill over into real behaviour;
- Availability of lethal weapons like fire-arms significantly increases the possibility of both fatal and non-fatal injuries;
- Consumption of alcohol and other drugs is linked to almost 2/3 of cases of violence according to several studies.

Violence due to war and political unrest is fairly common in several countries. Organized and unorganized, ethnic and communal violence are well known in some places.
Suicides have been increasing at an alarming rate in SEAR countries. Incidence rates of 11 per lac population in Bangladesh, 26 per lac population in India, 8 per lac in Sri Lanka, and 22 per lac in Thailand; per year have been reported. Nearly 70 per cent of suicides in all countries have been reported in the age group of 15–34 years with male-female ratio of 1:1.2 to 1:3 from different countries. Poisoning, hanging, self-immolation and drowning are the most commonly reported methods of suicide [17].

In India, an average of 369 suicides take place every day, out of these 248 are committed by males and 121 by females (62 are house wives), Family problems (89) and illness (72) are the main cause of suicides. Majority cases are below 29 years of age (136) followed by 30–44 years of age group (125) [10].

References
Since India became independent, several measures have been undertaken by the National Government to improve the health of the people. Prominent among these measures are the NATIONAL HEALTH PROGRAMMES, which have been launched by the Central Government for the control eradication of the communicable diseases, improvement of environmental sanitation, raising the standard of nutrition, control of population, and improving rural health. Various international agencies like WHO, UNICEF, UNFPA, World Bank, as also a number of foreign agencies like SIDA, DANIDA, NORAD and USAID have been providing technical and material assistance in the implementation of these programmes. A brief account of these programmes which are currently in operation is given below:

NATIONAL VECTOR BORNE DISEASE CONTROL PROGRAMME

The National Vector Borne Disease Control Programme (NVBDCP) is implemented in the State/UT’s for prevention and control of vector borne diseases namely Malaria, Filariasis, Kala-azar, Japanese Encephalitis (JE), Dengue and Chikungunya. The Directorate of NVBDCP is the nodal agency for planning, policy making and technical guidance and monitoring and evaluation of programme implementation in respect of prevention and control of these vector borne diseases under the overall umbrella of NRHM. The States are responsible for planning, implementation and supervision of the programme. The vector borne diseases are major public health problems in India. Chikungunya fever which has re-emerged as epidemic outbreaks after more than three decades has added to the problem. The prevention and control of vector borne diseases is complex; as their transmission depends on interaction of numerous ecological, biological, social and economic factors including migration (1).

Out of the six vector borne diseases, malaria, filariasis, japanese encephalitis, dengue and chikungunya are transmitted by different kind of vector mosquitoes, while kala-azar is transmitted by sand flies. The transmission of vector borne diseases in any area is dependent on frequency of man-vector contact, which is further, influenced by various factors including vector density, biting time, etc. Mosquito density is directly related with water collection, clean or polluted, in which the mosquitoes breed.

Under NVBDCP, the three pronged strategy for prevention and control of VBDs is as follows: (i) Disease management including early case detection and complete treatment, strengthening of referral services, epidemic preparedness and rapid response (ii) Integrated vector management (IVM) for transmission risk-reduction including indoor residual spraying in selected high-risk areas, use of insecticide treated bed-nets, use of larvivorous fish, anti-larval measures in urban areas, source reduction and mirror environmental engineering (iii) Supportive interventions including behaviour change communication (BCC), public private partnership and inter-sectoral convergence, human resource development through capacity building, operational research including studies on drug resistance and insecticide susceptibility, monitoring and evaluation through periodic reviews/field visits, web based management information system, vaccination against JE and annual mass drug administration against lymphatic filariasis (1).

(A) MALARIA

The programme began originally as National Malaria Control Programme in 1953, during the First Five Year Plan. Because of the spectacular success achieved in the control of malaria, the control programme, was converted in 1958 into an eradication programme, with the objective of eradicating malaria once and for all from the country. Since then the programme has undergone many changes and the milestones of malaria control activities in India are as shown below (2):

Milestones of malaria control activities in India

2008 World Bank funded National Malaria Control Project launched
2009 Introduction of LLINs
2010 Introduction of bivalent RDT

The main activities of the programme are:
1. Formulating policies and guidelines.
2. Technical guidance.
3. Planning.
4. Logistics.
5. Monitoring and evaluation.
6. Coordination of activities through the States/Union Territories and in consultation with national organizations such as National Centre for Disease Control (NCDC), National Institute of Malaria Research (NIMR).
7. Collaboration with international organizations like the WHO, World Bank, GFA
t and other donor agencies.
8. Training.
9. Facilitating research through NCDC, NIMR, Regional Medical Research Centres etc.
10. Coordinating control activities in the inter-state and inter-country border areas.

Organization (2)

There are 19 Regional Offices for Health and Family Welfare under Directorate of Health Services, Ministry of Health and Family Welfare, located in 19 states, which play a crucial role in monitoring the activities under NVBDCP. These offices are equipped with malaria trained staff.

The state governments are required to plan and implement the malaria control operations in their respective states. Every state has a Vector Borne Disease Control Division under its Department of Health and Family Welfare. It is headed by the State Programme Officer (SPO) who is responsible for supervision, guidance and effective implementation of the programme and for coordination of the activities with the neighbouring States/UTs. States are responsible for the procurement of certain insecticides for indoor residual spray (IRS), spray equipment and certain anti-malarials, the central government supplies DDT and larvicides.

Each state has established a State Vector Borne Disease Control Society, which includes civil society and sometimes private sector representation. These are now merged with similar entities for other centrally sponsored schemes into a single state-level Health and Family Welfare Society. The main role of these societies is to channelise funds from GOI to the states and onwards to districts for financing of the programmes. They also play a role in district level planning and in monitoring of programme activities within districts.

At the divisional level, zonal officers have technical and administrative responsibilities of the programme in their areas under the overall supervision of Senior Divisional Officers (SDOs).

At the district level, the Chief Medical Officer (CMO)/District Health Officer (DHO) has the overall responsibility of the programme. At the district level, district malaria offices have been established in many places headed by the DVBCP officer to assist the CMO/DHO. This office is the key unit for the planning and monitoring of the programme. Spray operations are the direct responsibility of DMO/DVBCP officer in the entire district under overall supervision of CMO and collaborative supervision/monitoring by PHC's Medical Officer. There is one Assistant Malaria Officer (AMO) and Malaria Inspector (MI) to assist him (2).

In many districts, District Vector Borne Disease Control Societies (now merged with District Health Societies under NRHM) have been established to assist the management of fund raising, and planning of programme activities.

The laboratories have been decentralised and positioned at the PHCs. The medical officer - PHC has the overall responsibility for surveillance and laboratory services, and also supervises the spray. Case detection management and community outreach services are carried out by MPPs as well as ASHAs and other community health volunteers.

DRUG DISTRIBUTION CENTRES AND FEVER TREATMENT CENTRES

With the increasing number of malaria cases, the demand for antimalarial drugs has increased tremendously. It becomes clear that drug supply only through the surveillance workers and medical institutions was not enough. This led to the establishment of a wide network of Drug Distribution Centres and Fever Treatment Depots and malaria clinics at some sub-centres. Drug Distribution Centres are only to dispense the anti-malarial tablets as per NMEP schedules. Fever Treatment Depots collect the blood slides in addition to the distribution of antimalarial tablets. These centres are manned by voluntary workers from the community.

URBAN MALARIA SCHEME

The urban malaria scheme was launched in 1971 to reduce or interrupt malaria transmission in towns and cities. The method uses spray vector control by intensive antilarval measures and drug treatment. About 7.4 per cent of the total cases of malaria and 10.9 per cent of deaths due to malaria are reported from urban areas. Maximum cases are reported from Chennai, Vadodara, Vishakhapatnam, Ahmedabad, Kolkata, New Mumbai, Vellore etc. (3). The vector of malaria in the urban areas breeds largely in man-made containers including overhead tanks and underground water storage tanks, water coolers, cisterns, roof gutters, flower vases, bottles and ornamental ponds, old tyres etc., which can collect water. Large construction activities provide suitable breeding sites for mosquitoes. Influx of migrant labour, from malarious zones contribute to increase in incidence. Control of urban malaria lies primarily in the implementation of civil bye-laws to prevent mosquito breeding in the domestic and peridomestic areas. Use of larvivorous fish in the water bodies such as slow moving streams, ornamental ponds etc. is recommended. Larvicides are used for water bodies which are unsuitable for fish use (2). The urban malaria scheme under national vector disease control programme is presently protecting 116 million population from malaria and other mosquito borne diseases in 131 towns in 19 states and Union Territories. The civic bye-laws have been enacted and implemented in Delhi, Mumbai, Kolkata, Chandigarh, Bangalore, Chennai, Ahmedabad and Goa etc. (5).

The Expert Committee on Malaria had recommended the inclusion of all urban areas with more than 50,000 population and reporting slide positivity rate of 5 per cent and above, under Urban Malaria Scheme and introduction of active surveillance under this scheme.
Strategic action plan for malaria control in India (2012–2017)

The vision of strategic action plan is a substantial and sustained reduction in the burden of malaria in the year and mid term, and the elimination of malaria in the long term, when new tools, in combination with strengthening of health systems, will make national elimination possible.

Malaria control is now incorporated into the health service delivery programmes under the umbrella of NRHM. This provides opportunities for strengthening malaria prevention and treatment services close to the community. All available methods and means are being used to deliver these interventions, at entry-level facilities (e.g. CHCs, PHCs, and sub-centres), community outreach services using community health workers and volunteers (ASHAs) at village level, NGOs, private-sector providers and district and regional health facilities and hospitals.

Objective

To achieve API < 1 per 1000 population by the end of 2017.

Goals

The national goals for strategic plan are (2):

1. Screening all fever cases suspected for malaria (60%) through quality microscopy and 40% by rapid diagnostic test.
2. Treating all P. falciparum cases with full course of effective ACT and primaquine, and all P. vivax cases with 3 days chloroquine and 14 days primaquine.
3. Equipping all health institutions (PHC level and above), especially in high-risk areas, with microscopy facility and RDT for emergency use and injectable artemisinin derivatives.
4. Strengthening all district and sub-district hospitals in malaria endemic areas as per PHVs with facilities for management of severe malaria cases.

Outcome Indicators

The outcome indicators of strategic plan are:

1. At least 80% of those suffering from malaria get correct, affordable, appropriate and complete treatment within 24 hours of reporting to the health system, by the year 2017.
2. At least 80% of those at high risk of malaria get protected by effective preventive measure such as ITN/LLIN or IRS by 2017.
3. At least 10% of the population in high-risk areas is surveyed annually (annual blood examination rate > 10%).

Impact Indicators

The impact indicators of strategic plan are:

1. To bring down annual incidence of malaria to less than 1 per 1000 population at national level by 2017.
2. At least 50% reduction in mortality due to malaria by the year 2017, taking 2010 level as baseline.

Strategies

India’s national malaria strategic plan (2012–17) is in line with the following broad strategies of the regional malaria strategy of WHO/SEARO:

- Reform approaches to programme planning and management.
- Improve and enhance surveillance and strengthen data collection systems.
- Scale up coverage and proper use of insecticide treated bed nets.
- Target interventions to risk groups.
- Scale up control of P. falciparum.

Reforms are an ongoing process and during the current five year strategic plan, continued use of ACT, and RDTs at village level and IVM along with LLIN use is envisaged. These strategies are congruent with the WHO global recommendations, and offer the possibility of dramatically improved outcomes for malaria. Reforms are also in place, or underway, to address governance issues to strengthen accountability.

Categorized strategic interventions for achieving pre-elimination status

During the 11th Plan-Year Plan period (2007–12), the malaria strategy adopted was for malaria control. At present, malaria incidence in many states in India is very low. In view of the feasibility of shrinking the map of malaria and progress towards malaria elimination (defined as no indigenous transmission, i.e., API less than one) it is proposed to change the strategies according to malaria endemcity at state and district level. This approach is expected to lead to reduction in malaria incidence in high endemic areas and sustain reduced incidence in low endemic areas to pave the way for the country to enter into the "pre-elimination stage". This approach requires appropriate inputs in terms of technical, logistical and financial support.

The Technical Advisory Committee (TAC) for the programmes has approved the following category specific broad strategies (3):

<table>
<thead>

</tbody>
</table>
Major activities according to API (2)

For areas having API less than 1
1. Vector control by minor engineering measures like dolting, jeeoweeding and cleaning of canals and irrigation channels, biological control by use of larvicides and environmental management.
2. Involving PPIs by sensitizing them in rural areas and municipal bodies in urban areas.
3. Cooperation from NHSCs and nodal officers from MNREGA.

For areas having API between 1–2
1. Vector control by source reduction and biological control.
2. Active surveillance by ASHA/ANM and positioning of MPWs in SCS where there is provision for 2nd ANM.

For areas having API between 2–5
1. Vector control by distribution of LLIN if acceptability of IRS is low @ 2 LLIN per household of 3 members.
2. For areas which can be supervised and accessible, quality IRS for selective vector control based on epidemiological impact of earlier vector control measures, if needed; these areas can also be provided with LLINs.

For areas having API above 5
a. For areas having perennial transmission (more than 5 months in a year)
1. 2 rounds of IRS with DDT and 3 rounds with malathion.
2. Priority distribution of LLINs as per the guidelines.
3. Vector biomonitoring studies for future charge of strategy.

b. For areas having seasonal transmission (less than 5 months in a year)
1. 1 round of IRS with DDT before start of transmission.
2. Focal array whenever and wherever needed.
3. Priority distribution of LLINs as per the guidelines.

For surveillance, the states which are reporting an API of <1 for three consecutive years shall initiate action for declaring malaria as a notifiable disease in the state (2).

Malaria control strategies
The strategies for prevention and control of malaria and its transmission are:
1. Surveillance and case management
   - Case-detection (passive and active)
   - Early diagnosis and complete treatment
   - Sentinel surveillance
2. Integrated vector management (IVM)
   - Indoor residual spray (IRS).
   - Insecticide treated bed nets (ITNs)/Long Lasting Insecticidal Nets (LLINs).
   - Antibacterial measures including source reduction.
3. Epidemic preparedness and early response
4. Supportive interventions
   - Capacity building
   - Behaviour change communication (BCC)
   - Intersectoral collaboration
   - Monitoring and evaluation
   - Operational research and applied field research.

Surveillance and case management
Surveillance (2)
The primary purpose of case management is to shorten the duration of illness prevent the development of severe disease and death, especially in falciparum malaria. Therefore, case management for malaria is based on early diagnosis followed immediately by effective treatment. Early effective treatment is also important for limiting transmission of the disease.

The malaria surveillance system in India was initially set up in the early 1960s to detect remaining foci at that time, when the country was aiming to eliminate the disease and, not to measure the burden of the disease. The system has since been adapted to the needs of control and now monitors malaria incidence trends and geographic distribution. The aim is to target control interventions in high transmission areas and assessing their impact. Surveillance also plays a key role in the early detection of outbreaks.

Active case detection (ACD) is carried out in rural areas with blood smears collected by MPWs during fortnightly house visits. Passive case detection (PCD) is done in fever cases reporting to peripheral health volunteers (ASHAs) and at sub-centres, malaria clinics, CHC, and other secondary and tertiary level health institutions that patients visit for treatment. ASHA and other volunteer workers provide diagnostic services by RDTs, and st PHCs by examination of blood smears. In villages where no ASHA or other volunteer has been trained and deployed for providing early diagnosis and effective treatment, ACD and case management is done by the MPWs.

The surveillance data of NVBDCP reflects malaria trends reasonably well because the ABER in the country as a whole has remained relatively constant at about 10%, and the surveillance system has not undergone any major changes. The ABER is, however, low in a few states, while in most of the high endemic areas it is much above 10%. Microscopy remains the best method of diagnosis on account of its high
sensitivity and specificity. It is also more economical in facilities where large number of slides are examined daily.

There are about 100 million blood slides collected from fever patients in India. Of these, about 1.5 million malaria cases are detected. The new norms for case management emphasise quality care for patients. The implementation of use of Rabbit Diagnostic Tests (RDTs) and Artequant combination therapy (ACT) and the improvements in service delivery is expected to affect greater number of fewer cases to the programme in the coming years. The programme also plans to supply RDT kits to primary providers in return for data. The current level of screening of 100 million fever cases will not be reduced as it is aimed to screen 10% of the population, even though the disease transmission is expected to reduce.

During 2008, the NVBDCP introduced the use of RDT in 8 states under the World Bank assisted EMCP for early diagnosis of malaria. In the year 2012, bivalent RDT were introduced in the programme, to detect Plasmodium falciparum and P. vivax. Since then, the programme has procured and distributed RDTs to community level workers/health workers who have been trained to use them to enable timely diagnosis in these areas. In remote and inaccessible rural and tribal areas, RDTs are now the established method of choice for malaria diagnosis.

Parameters of malaria surveillance

By definition, surveillance also implies the continuing scrutiny of all aspects of occurrence and spread of a disease, that are pertinent to effective control. Included in these are the systematic collection and evaluation of field investigations, etc. The following parameters are widely used in the surveillance of malaria: - a. Annual parasite incidence (API); b. Annual blood examination rate (ABER); c. Annual falciparum incidence (AFI); d. Slide positivity rate (SPR); e. Slide falciparum rate (SFR).

Case management

According to the revised drug policy, there is no scope of presumptive treatment in malaria control. The new drug policy of 2013 is being followed in the country. For further details please refer to page 262, chapter 5.

Sentinel surveillance

One of the weaknesses of the existing malaria surveillance system is the lack of articulation with hospitals, which means that severe malaria cases are not reported separately and that only a small fraction of malaria deaths are recorded. Therefore, sentinel surveillance is being established in high endemic districts, by selecting in each district, depending on its size, 1–3 sentinel sites in large hospitals for recording of all out-patient and in-patient cases of malaria, and malaria related deaths.

Integrated vector management (IVM)

The NVBDCP aims to achieve effective vector control by the appropriate biological, chemical and environmental interventions of proven efficacy, separately or in combination as appropriate to the area through the optimal use of resources. Efforts are made for collaboration with various public and private agencies and community participation for vector control. Integration of IVM is done by using identical vector control methods to control malaria and leishmaniasis in rural areas, and malaria and dengue in urban areas, to achieve cost-effectiveness and synergy. The IVM includes safe use of insecticides and monitoring of insecticide resistance. The measures of vector control and protection include:

- Measures to control adult mosquitoes: Indoor Residual Spraying (IRS) and thermal fogging
- Anti larval measures: chemical, biological and environmental
- Personal protection: use of bed-nets, including insecticide treated nets

The national malaria control programme is currently using IRS as the primary method of vector control in rural settings, and anti larval measures in the urban areas. Insecticide treated bed-nets have been introduced in the programme and the programme envisages a scale up in their use as vector control option for full population coverage, which will replace IRS in areas, where operational factors indicate that this method alone will give sufficient impact.

High-risk areas and populations

Micro-stratification has been applied in malaria control for decades, and will now be applied more rigorously, as resources are increasing, making it possible to protect maximum number of populations living in high risk areas. Using local surveillance data and vector control experience, including the knowledge, habits and attitudes of the local community, district VBDCC staff will be responsible for identification and mapping of high risk areas and risk populations as a basis for planning vector control. The stratification will be flexible, but firm enough to provide the cornerstone for planning, monitoring and evaluation.

IRS was carried out at the beginning of the NMEP in 1958 in all rural areas. However, under the MPO in 1977, it was decided that IRS to cover only high-risk rural areas, i.e., those areas with API ≥ 2. The Technical Advisory Committee on Malaria (2002) further prioritised the criteria for undertaking IRS, which at that time the only vector control method recognized for broad application. These criteria are as follows:

1. To spray on priority basis with suitable insecticide all areas with ≥ 5 API where ABER is 70 per cent or more, taking the sub-centre as a unit.
2. To spray on priority basis with suitable insecticide all areas reporting ≥ 5 per cent SPR (based on past collection of blood slides), if the ABER is below 10 per cent.
3. Due priority be accorded for spray if PY proportion is more than 50 per cent.
4. To accord priority for IRS in areas with less than API 5 or SPR<5 per cent in rural of drug-resistant foci, project areas with population migration and aggregation or other vulnerable factors including peri-cantonment areas.
5. To make provision for insecticidal spraying in epidemic situation.
6. Other parameters including entomological, ecological etc. may also be considered while prioritizing areas for spraying.

As much as possible, the village is to be the unit of intervention, but in some districts, data available with knowledge of ecological conditions may make it more rational to classify whole sub-centre areas as high-risk areas. High risk areas and populations will be re-defined at least annually. Such villages shall be protected by indoor residual spray and insecticide treated nets and the coverage will be more than 90 per cent, whatever may be the intervention.
The population living in areas with API ≥ 5 (69.1 million) is planned to be covered by LLNs and population living in endemic areas registering API ≥ 2 is covered with conventional net treated with insecticides and IRS. Conventional nets treated with insecticides will continue to be used in areas registering API 2 to 5. IRS is still the preferred method of vector control in areas with very hot summers and where ITNs are not acceptable to population.

A population of about 80 million is at present being covered by IRS in the country. DDT is the insecticide of choice; in areas where the vector has shown resistance to DDT, the alternatives are malathion and synthetic pyrethroids. Two rounds of spraying are done for DDT and synthetic pyrethroids to provide protection during the entire transmission season, and in the case of malathion, three rounds of spraying are required. About 60 per cent of the high risk areas targeted under IRS are under coverage with DDT. The real coverage by IRS is, however, limited by the low community acceptance due to the white marks left on plastered surface, acid smell associated with malathion, re-plastering of walls after completion of IRS etc.

**Malaria paradigms/ecotopes (2)**

The association between malaria and various ecological situations have been studied in India since the early part of the 20th century. There is considerable heterogeneity in malaria transmission characteristics between and within the states of the country, and many ecotypes/paradigms of malaria have been recognized. They are discussed in detail on page 264 chapter 5. The vector control recommendations according to the classification, when ITNs have emerged as a vector control option are as shown in Table 2.

Presently, malaria burden in the country is highly concentrated in a few forest-tribal states and areas. In most of these states, vector control interventions are limited to villages with API ≥ 5 or other high risk criteria, due to resource constraints. The North-East has specific difficulties in implementation and monitoring due to various reasons, including difficulty of terrain and exorbitant cost of An. dirus. It is also possible that reductions in malaria burden in high burden areas will translate to a reduction of malaria risk in low burden areas in the country inspite of continued population movements.

**Behaviour change communication (BCC)**

BCC is a systematic process that motivates individuals, families and communities to change their inappropriate or unhealthy behaviour, or to continue a healthy behaviour. BCC is a key supportive strategy for malaria prevention and treatment under NVBDCP.

BCC is directed at: (a) early recognition of signs and symptoms of malaria; (b) early treatment seeking from appropriate provider; (c) adherence to treatment regimens; (d) ensuring protection of children and pregnant women; (e) use of ITNs/LLNs; (f) acceptance of IRS, etc.

**Anti-malaria month campaign**

Anti-malaria month is observed every month in the month of June throughout the country, prior to the onset of monsoon and transmission season, to enhance the level of awareness and encourage community participation through mass media campaign and inter-personal communication and consolidate Inter-sectoral collaborative efforts with other government departments, corporate and voluntary agencies at national, state and district levels.

**Interaction of malaria control with other health programmes**

The other main public health programmes related to malaria control are:

1. Integrated Disease Surveillance Project (IDSP): The project, with weekly fever alerts is increasingly providing the early warning signals on malaria outbreaks.

2. Other vector borne diseases. Dengue and malaria control activities overlap in many urban areas, malaria and kala-azar in a few districts of Jharkhand, and malaria and filariasis in some areas including a few districts of Odisha.

3. Reproductive and child health: Antenatal care services are utilized in distribution of LLNs to pregnant women

Source: (2)
in some areas of the country. Janani Sreeavas Sha Yojna also makes provision of bed-nets distribution to pregnant women. Changes in the malaria case management norms have been included in the Integrated Management of Neonatal and Childhood Illness.

The major externally supported projects (I)

Additional support for combating malaria is provided through external assistance in high malaria risk areas. There are two such externally funded projects which are currently being implemented for malaria control:

(i) Global Fund supported Intensified Malaria Control Project (IMCP II).
(ii) World Bank supported project on Malaria Control & Kala-azar Elimination.

The areas covered under these projects are as under:

(i) The Global Fund supported Intensified Malaria Control Project II (IMCP II) : Global Fund Round 9 supported IMCP II is being implemented since October 2010 for a period of five years in 7 North-East states. The project area covers a population of 46 million in 46 districts. The strategy of the project is early diagnosis and complete treatment, integrated vector control including promotion of ITNs (LLINs).

Additional support provided in project area is as follows:

a. Human resource such as consultants and support staff for project monitoring units at state and district level and malaria technical supervisor and laboratory technicians at sub-district level;

b. Capacity building of Medical Officers/Lab. Technicians/Fever Treatment Depots/volunteers etc.;

c. Commodities such as long-lasting insecticidal nets (LLINs), rapid diagnostic tests for quick diagnosis of malaria, alternate drugs (Artesunate Combination Therapy, in particular) for treating severe malaria cases; and

d. Planning and administration including mobility support, monitoring, evaluation and operational research (studies on drug resistance and entomological aspects).

(ii) The World Bank supported project on malaria control and kala-azar elimination : This project was approved for 5 years effective from March 2009 to December 2013. The total financial outlay for this project is Rs. 1000 crores. This project was initiated in 93 malarious districts of eight states, namely Andhra Pradesh, Chhattisgarh, Gujarat, Jharkhand, Madhya Pradesh, Maharashtra, Orissa & Karnataka and 46 kala-azar districts in three states namely Bihar, Jharkhand and West Bengal. The project is being implemented in two phases. Phase-I covered 50 most malaria endemic districts in five states, namely Andhra Pradesh, Chhattisgarh, Madhya Pradesh, Orissa and Jharkhand, and 46 kala-azar districts in Bihar, Jharkhand & West Bengal. From 3rd year, Phase-II is being implemented in remaining (43) malaria districts. Additional 31 high endemic districts from three states namely Jharkhand, Orissa and West Bengal have been included in Phase-II for malaria control making a total of 124 districts to be supported for malaria control and kala-azar elimination under the World Bank project.

Additional supports provided in this project are:

a. Provision of human resource like consultants and support staff at national, state, district and sub-district level for surveillance and monitoring;

b. Promotion and use of long lasting insecticidal nets (LLINs) in high malaria endemic areas;

c. Strong BCC/IEC activities at sub-district level;

d. Supply of rapid kits for malaria diagnosis and drug Artesunate Combination Therapy for treatment of P. falciparum cases.

- At least 80 per cent of those suffering from malaria get correct, affordable and appropriate treatment within 24 hours of reporting to the health system, by the year 2012.
- At least 80 per cent of those at high risk of malaria get protected by effective preventive measures such as ITNs/LLINs or IRS by 2012.

An overview of actions with tentative targets for reduced malaria in different areas of the country for the period up to 2017 are as shown in Table 3.

Source: (2)
ELIMINATION OF LYMPHATIC FILARIASIS

The disease is endemic in 250 districts in 20 states and UTs. According to recent estimates about 600 million people are exposed to the risk of infection (1).

The National Filariasis Control Programme has been in operation since 1965. In June 1978, the operational component of the NFCP was merged with the urban malaria scheme for maximum utilization of available resources. The training and research component, however, continues to be with the Director, National Institute of Communicable Diseases, Delhi.

Training in filariology is being given at three Regional Filaria Training and Research Centres situated at Calicut (Kerala), Rajahambudiy (A.P.) and Varanasi (U.P.) under the National Institute of Communicable Diseases, Delhi.

Besides, 12 headquarters bureaux are functioning at the state level.

Filariasis control strategy includes vector control through larval operations, source reduction, detection and treatment of microfilaria carriers, morbidity management and IEC. National Filariasis Control Programme is being implemented through 206 filaria control units, 199 filaria clinics and 27 survey units, primarily in endemic urban towns. In rural areas anti-filaria medicines and morbidity management services are provided through primary health care system.

In India, the National Health Policy (2002), envisages elimination of lymphatic filariasis (ELF) by 2015. The elimination is defined as lymphatic filariasis ceases to be a public health problem, when the number of microfilaria carriers is less than 1 per cent and the children born after initiation of ELF are free from circulating antigenemia (presence of adult filaria worm in human body).

The strategy of lymphatic filariasis elimination is through:

(a) Annual Mass Drug Administration (MDA) of single dose of DEC; and (b) monthly larval control.

To achieve elimination of lymphatic filariasis, during 2004 the Govt. of India launched annual MDA with single dose of DEC tablets in addition to scaling-up home based foot care and hydrocele operation. The co-administration of DEC + Albendazole has been upscaled since 2007. The programme covers 202 districts in 2004 whereas by the year 2007, all the 250 LF endemic districts were covered. The mass drug administration starts in the month of November and the coverage has improved from 72.4 per cent in the year 2004 to 87.5 per cent in 2012.

During the year 2012, two districts of Goa, Puducherry, Daman & Diu and 16 districts of Tamil Nadu stopped MDA as validation process was initiated through Transmission Assessment Survey (1).

The line listing of lymphoedema and hydrocele cases were initiated since 2004 by door-to-door survey in filaria endemic districts. The updated figure till December 2012 reveals about 12 lac cases with clinical manifestation of lymphoedema (8 lacs) and hydrocele (4 lacs). Initiation has also been taken to demonstrate the simple washing of foot to maintain hygiene for prevention of secondary bacterial and fungal infection in chronic lymphoedema cases, so that the patients get relief from frequent acute attacks.

The microfilaria survey in all the implementation units is being done through night blood survey before MDA. The survey is done in 4 sentinel and 4 random sites collecting total 4000 slides (500 from each site). There is definite evidence of microfilaria reduction in the MDA districts. However, the coverage of population with MDA should be above 80 per cent persistently for 5–7 years, which would reduce microfilaria load in the community, and thereby, interrupt the transmission (3).

(C) KALA-AZAR

Kala-azar is now endemic in 31 districts of Bihar, 4 districts of Jharkhand, 11 districts of West Bengal and 6 districts of Uttar Pradesh. Besides sporadic cases in few other districts of Uttar Pradesh. A centrally sponsored programme was launched in 1990–91. This has brought down the incidence of the disease from 77,102 cases in 1992 to 13,869 cases in 2013 (1).

The strategies for Kala-azar elimination are:

(a) Enhanced case detection and complete treatment including introduction of PR39 rapid diagnostic kits and oral drug Miltefosine for treatment of Kala-azar cases; (b) Interruption of transmission through vector control. It has been decided to replace DDT with synthetic pyrethroids for the purpose of fogging to eliminate sandfly, as the insect is becoming resistant to DDT; (c) Communication for behavioural impact and intersectoral convergence; (d) Capacity building; (e) Monitoring, supervision and evaluation; (f) Research guidelines on prevention and control of Kala-azar have been developed and circulated to the states.

ACTIVE CASE SEARCH: The frequency of case searches has been increased from a single annual case search to quarterly case searches. The active case searches are carried out during a fortnight designated as the "Kala-azar Fortnight", during which the peripheral health workers and volunteers are engaged to make door-to-door searches and refer the cases conforming to the case definition of kala-azar and PKDL to the treatment centres for definitive diagnosis and treatment (3).

An incentive amount of Rs. 300 is provided to ASHA for identifying each case of kala-azar and Rs. 100 for ensuring community support during insecticide spraying. Even the patient being treated in the hospital will be given Rs. 500 as compensation of daily wage for the time he spends in the hospital during the treatment. This revised strategy of total eradication of kala-azar was launched on 2nd September 2014.

The new strategy also includes introduction of Rapid Diagnostic Kit developed by ICMR into the programme and single dose treatment with Liposomal Amphotericin B, which is given intravenously in 10 mg dose. It is to reduce the human reservoir of infection. WHO will supply the drug free of cost (4).

(D) JAPANESE ENCEPHALITIS

Japanese encephalitis is a disease with high mortality rate and those who survive do so with various degrees of neurological complications. During the last few years it has become a major public health problem. States of Andhra Pradesh, West Bengal, Assam, Tamil Nadu, Karnataka,
For early diagnosis ELISA based NSI kits have been introduced under the programme which can detect the cases from 1st day of infection. IgM capture ELISA tests can detect the cases after 5th day of infection.

The GOI has taken the following steps for prevention and control of dengue (6):
- Monitoring the situation through reports received from state health authorities.
- A mid-term plan for prevention and control of dengue has been developed in 2011 and circulated to the states for implementation. The main components of mid-term plan for prevention and control of dengue are as follows:
  (a) Surveillance: Disease and entomological surveillance
  (b) Case management: Laboratory diagnosis and clinical management
  (c) Vector management: Environmental management for source reduction, chemical control, personal protection and legislation
  (d) Outbreak response: Epidemic preparedness and media management
  (e) Capacity building: Training, strengthening human resource and operational research
  (f) Behavioural change communication: Social mobilization, and information, education and communication (IEC)
  (g) Inter-sectoral coordination: with ministries of urban development, rural development, panchayat raj, surface transport and education sector
  (h) Monitoring and supervision: Analysis of reports, review, field visit and feedback

(F) CHIKUNGUNYA FEVER

Chikungunya fever is a debilitating non-fatal viral illness, re-emerging in the country after a gap of three decades. Govt. of India is continuously monitoring the situation. Guidelines for reporting and control of the disease have been prepared. Since same vector is involved in the transmission of dengue and chikungunya, strategies for transmission risk reduction by vector control are also the same. Support in the form of logistics and funds are provided to the states.

For carrying out proactive surveillance and enhancing diagnostic facilities for chikungunya, the 137 sentinel surveillance hospitals involved in dengue in the affected states also carry out chikungunya tests. The diagnostic kits are provided through National Institute of Virology, Pune by the central government.

NATIONAL LEPROSY "ERADICATION" PROGRAMME

The National Leprosy Control Programme (NLCP) has been in operation since 1955, as a centrally aided programme to achieve control of leprosy through early detection of cases and D2S (dapsone) monotherapy on an antimalarial basis. The NLCP moved ahead initially at a slow pace, presumably for want of clear-cut policies or operational objectives for nearly two decades (7). The programme gained momentum during the Fourth Five Year Plan after it was made a centrally-sponsored programme. In 1980 the Government of India declared its resolve to
“eradicate” leprosy by the year 2000 and constituted a Working Group to advise accordingly. The Working Group submitted its report in 1982 and recommended a revised strategy based on multi-drug chemotherapy aimed at leprosy “eradication” through reduction in the quantum of infection in the population, reduction in the sources of infection, and breaking the chain of transmission of disease. In 1983 the control programme was redesigned National Leprosy “Eradication” Programme with the goal of eradicating the disease by the turn of the century. The aim was to reduce case load to 1 or less than 1 per 1,000,000 population.

To strengthen the process of elimination of leprosy in the country, the first World Bank supported project was introduced in 1993. On completion of this project, the 2nd phase of project with World Bank support was started in 2001–02 which ended in December 2004. Since then, the programme is being continued with Government of India funds with technical support from WHO and International Federation of Anti-Leprosy Association (ILEP) organizations. The programme has been integrated with general health care system in 2002–03, since then leprosy diagnosis and treatment services are available at all PHCs and government hospitals.

The components of the programme are as follows:
1. Decentralized integrated leprosy services through general health care system;
2. Capacity building of all general health services functionaries;
3. Intensified information, education, and communication;
4. Prevention of disability and medical rehabilitation; and
5. Intensified monitoring and supervision.

After introduction of MDT, the recorded case load of leprosy came down from 57.6 cases per 10,000 population in 1981 to less than one at the national level in December 2005, and the country could achieve the goal of leprosy elimination at national level as set by the National Health Policy (2002). 33 states/UTs achieved the status of leprosy elimination. Only 2 States/UTs viz. Chattisgarh and Dadra & Nagar Haveli are yet to achieve elimination (1).

A total of 209 high endemic districts were identified for special action during 2012–13. 1792 blocks and 150 urban areas were identified for special activities, i.e., house to house survey using IEC and capacity building of the workers and volunteers (1). Major initiatives

Major initiatives taken are as follows:
1. More focus has now been given to new case detection than prevalence which only gives the number of cases on record at a point in time. The new case detection rate is the main indicator for programme monitoring.
2. Treatment completion rate has been taken as an important indicator to be calculated by states at yearly basis.
3. More emphasis is being given on providing disability prevention and medical rehabilitation (DPRM) services to leprosy affected persons. The aid provided is as follows:
   a. Dressing materials, supportive medicines and ulcer kits are provided to leprosy affected persons with ulcer and wounds. These services are also provided to leprosy affected persons residing in self settled colonies (b) Micro-cellular rubber footwear is provided for protection of insensitive feet. 41 NGOs in the country and 42 Government Medical Colleges have been strengthened for providing reconstructive surgery services to leprosy affected persons for correction of their disability.
   c. As an amount of Rs. 5000/- is provided as incentive to each leprosy affected person and their family undergoing reconstructive surgery in these identified institutions to compensate for loss of wages.
   d. Support is also provided to government institutions/ PMR centers in the form of Rs. 5000/- per reconstructive surgery conducted.
4. ASHA has been involved in bringing out suspected leprosy cases from their villages for diagnosis and treatment at PHC and follow-up of confirmed cases for their treatment completion. To facilitate the involvement of ASHA in the programme, they are being paid incentive money as below:
   a. On confirmed diagnosis of case brought by them – Rs. 200/-
   b. On completion of full course of treatment of the case within specified time – PB leprosy case – Rs. 200/-, and HB leprosy case – Rs 400/-.
5. There are 612 self settled colonies in the country where more than 50,000 leprosy affected persons reside. Free medical facilities like care of ulcers, self care training, counselling and MCR footwear are provided to leprosy affected persons residing in these colonies through para-medical workers/NGOs on weekly/monthly basis.
6. Intensive IEC campaign with a theme “Towards Leprosy Free India” has been carried out towards further reduction of leprosy burden in the community, early reporting of cases and their treatment completion, provision of medical services and reduction of stigma and discrimination against leprosy affected persons. Awareness generation activities are carried out through mass media and local media.

Urban leprosy control programme

The urban leprosy control programme was initiated in 2005 to address the complex problem of larger population size, migration, poor health infrastructure and increasing leprosy cases in urban areas.

Under this component, assistance is provided to urban areas having population size of more than 1 lakh. For the purpose of providing graded assistance, the urban areas are grouped in four categories i.e. Township I, Medium Cities I, Medium Cities II, and Mega Cities (3).

Disability prevention and medical rehabilitation (DPRM)

The main activities carried out under DPRM are as follows (8):

1. Implementation of DPRM activities as per guidelines and reporting its outcome etc. treatment of leprosy reaction, ulcers, physiotherapy, reconstructive surgery and providing MCR footwear.
2. Introducing DPRM services - There are provision of services to persons with disabilities by various departments under different ministries. Convergence of NLEPs services into NRHM facilitates this integration.
3) To develop a referral system to provide prevention of disability services to all leprosy disabled persons in an integrated set-up.

The DPMR activities are planned to be carried out in a three tier system i.e. the primary level care (First level), secondary level care (Second level) and the tertiary level care (Third level). The primary level care institutions are all PHCs, CHCs, Sub-divisional hospitals and urban leprosy centres/disinfectaries. The secondary level care institutions are all District Head Quarter Hospitals and District Nucleus Units. The tertiary level care institutions are:

1. Central Government Institutes (CLTRI, Chingleput and RLTRI at Asha/Gauripur/Raipur)
2. ICMAE Institute, Agra.
3. ILEP supported Leprosy Hospitals.
4. All PMR Institutes and departments of medical colleges.
5) All National Institutes under Ministry of Social Justice and Empowerment.
6) Contractual surgeons skilled in RCS and Rehabilitation Programmes.

The referral system in NLEP is as shown in Fig. 1.

Decentralisation and institutional development: Integration of leprosy services into the general health care system has been completed. Services are available from all PHCs and other health centres where a medical officer is available. District nucleus has been formed to supervise and monitor the programme. State leprosy societies formed will merge with the state health society under the National Rural Health Mission.

As the disease is still prevalent with moderate endemicity in about 25 per cent of the country, the plan objectives are set as follows (9).

a. Elimination of leprosy i.e. prevalence of less than 1 case per 10,000 population in all districts of the country.

Source: (8)
b. Strengthen disability prevention and medical rehabilitation of persons affected by leprosy.

c. Reduction in the level of stigma associated with leprosy.

**Targets (9)**

The plan targets are as shown in Table 4.

<table>
<thead>
<tr>
<th>Indicator</th>
<th>Baseline (2011-12)</th>
<th>Targets (by March 2017)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prevalence Rate (PR)</td>
<td>543 districts (84.6%)</td>
<td>642 districts (100%)</td>

</tbody>
</table>

* GII Disability rate among new cases per million population to be reduced by 35% i.e. from 3 (2011-12) to 2 per million population by end of the 12th Plan.
** Based on the National Sample Survey (NSS) report, 2010-11.

**Programme strategy (9)**

To achieve the objectives of the plan, the main strategies to be followed are:

- Integrated leprosy services through general health care system.
- Early detection and complete treatment of new leprosy cases.
- Carrying out house-held contact survey for early detection of cases.
- Involvement of Accredited Social Health Activist (ASHA) in the detection and completion of treatment of leprosy cases on time.
- Strengthening of disability prevention and medical rehabilitation (DPMR) services.
- Information, Education & Communication (IEC) activities in the community to improve self-reporting to Primary Health Centre (PHC) and reduction of stigma.
- Intensive monitoring and supervision at block primary health centre/community health centre.

**Case detection and management (9)**

It is expected that the new cases will continue to occur regularly but the people are still hesitant to come forward to get themselves diagnosed and treated due to the stigma associated with the disease. Detection of the new cases at the early stage is the only solution to curb down the transmission potential in the community, and also to provide relief to the leprosy affected persons by preventing disabilities. It is therefore suggested that the states will draw up innovative plans:

- (i) To involve women including leprosy affected persons in case detection.
- (ii) To organize skin camps for detecting leprosy patients while providing services for other skin conditions.
- (iii) To undertake contact survey to identify the source in the neighbourhood of each child or multibacillary case.
- (iv) To increase awareness through the ANM, AWW, ASHA and other health workers to trace and put people affected by leprosy to motivate leprosy affected persons for early reporting to the medical officer.

Integrated leprosy services through all the primary health care facilities will continue to be provided in the rural areas. However, for providing technical support to the primary health care system, to strengthen the quality of services being provided, a team of well-qualified and trained medical officer and para-medical workers are placed at district level. This will be known as "District Leprosy Cell".

**Services in the urban areas (9)**

The health services in the urban areas differ from the rural areas because of non-availability of infrastructure like PHC and manpower for providing services upto domiciliary level. The services in urban areas are provided mainly through institutional level. Multiple organizations provide health services in urban localities without much of coordination amongst them.

More number of cases are detected in urban localities due to migration of people, availability of good quality institutions with easy accessibility, but treatment completion rate is less as compared to rural areas.

For the implementation of special action under the plan, about 524 urban localities have been identified out of 4,338 urban areas (census 2011). These localities are having population more than 100,000. Remaining areas will be covered by PHC services as in rural areas (9). These urban areas are divided into 4 categories: (a) Town and city (population 1 lac to 5 lacs) – 432 areas; (b) Medium city (population >5 lac to 1 million) – 83 areas; (c) Mega city (population >1 million to 4.5 million) – 34 areas; and (d) Areas with >4.5 million population – 5 areas.

**Additional activities in urban areas:** Component wise wise activities under NLEP will be carried out in the urban areas as in case of rural areas. Thus training, IEC, procurement and supply of MDT and other required medicines, MCR footwear, aids and appliances, payments of incentive for RSC etc. will be covered under regular provision. However, it is necessary to carry out following additional activities, which are specific to the needs of the urban population:

1. Identify human resources available with Government, civil societies, NGOs and private medical practitioners for leprosy services like suspect and referral. Population groups may be allocated to each human resource, and for follow-up of the cases.
2. Build capacity of the identified human resources at the time of induction and periodically.
3. Examination of all household contacts of all new cases at least once before the completion of treatment of index case.
4. Identify one referral centre in each urban location for diagnosis and to manage leprosy with or without complications.
5. Supervision and monitoring of the programme is the responsibility of the district leprosy officer, and medical officer of the referral centre.
6. Mobile health clinics of general health services include leprosy services on their visit to slums, peri-urban areas.
7. Develop a system of record keeping and reporting by each participating centre.
8. Develop a system of regular MDT supply to each health centre.
9. Procure additional requirement of drugs, dressing material, aids and appliances for inhabitants of leprosy colony requiring regular care for their disabilities.
10. Organize sensitization meetings for IEC and advocacy, participate in exhibitions, quit competition for awareness to reduce stigma.

Out of these 524 urban areas, 150 areas reported Ancrdr of > 10 per lac population during the year 2011–12. As in case of rural blocks, these urban areas will also be provided with one para-medical officer on contractual basis for monitoring the leprosy services in the area.

ASHA involvement

Accredited Social Health Activists (ASHA) will be involved to bring out suspected cases from their villages for diagnosis at PHC and after confirmation of diagnosis, will follow up the patients for completion of treatment. Her duties will be monitored by the concerned PHC medical officer. She will be entitled to receive incentive as below:

(i) At confirmation of diagnosis – Rs. 250/-
(ii) On completion of full course of treatment in time – Ph-additional Rs. 400/-

Activities to be performed by ASHA are as follows:

1. Search for suspected cases of leprosy i.e. before any sign of disability appears. Such early detection will help in prevention of disability and also cut down transmission potential.
2. Follow-up all cases for completion of treatment in scheduled time. During follow up visit, also look for symptoms of any reaction due to leprosy and refer them to the health worker/PHC for treatment. This will again reduce chances of disability occurring in cases under treatment.
3. Advise and motivate self-care practices by disabled cases for proper care of their hands and feet during the follow-up period. This will improve quality of life of the affected persons and prevent deterioration of disabilities.
4. Spreading awareness.

SET scheme

Under the SET scheme, the NGOs are presently involved in disability prevention and ulcer care, IEC, referral of suspected cases, referral for reconstruction surgery (RCS), research and rehabilitation. NGO support is mainly required for follow-up of under treatment cases in urban locations and difficult to reach areas.

Disability prevention and medical rehabilitation (DPMR)

The services under DPMR will cover reaction management, self-care practices, provision of MCR footwear, aids and appliances, referral services at district hospital and medical college/central leprosy institutions/ NGO institutions, and reconstructive surgery.

Incentive to patient

An incentive of Rs. 8000/- will be paid to all patients affected by leprosy undergoing major reconstructive surgery irrespective of their financial status. The payment will be made by the district leprosy officer. As of January 2021, there were 94 recognized RCS centres in the country.

Information, education and communication (IEC/BCC)

The IEC strategy during the 11th plan period will focus on communicating for behavioural changes in general public against the stigma and discrimination against the leprosy affected persons. Making the public aware about the availability of MDT, the importance of completing the course and that the leprosy affected person can live a normal life with the family (9).

Research into the basic problems of leprosy is also part of the activities of the NLEP. This is mainly carried out in the Government sector, viz., the Central JALMA Institute of Leprosy at Agra and the Central Leprosy Teaching and Training Institute at Chingelput, Chennai supported by Regional Training and Referral Institutes at Koda (Orissa), Ratnagiri (Maharashtra) and Faridpur (West Bengal).

IYLEP Agencies

The International Federation of Anti-Leprosy Associations is actively involved as partner in NLEP in India. ILEP is constituted by 10 agencies viz. The Leprosy Mission, Damien Foundation of India Trust, Netherlands Leprosy Relief, German Leprosy Relief Association, Lepra India, ALES, AIF, Fonilles-India, AERF-India and American Leprosy Mission. ILEP is providing support in the form of planning, monitoring and supervision of the programme, capacity building of general health care staff, IEC, providing re-construction surgery services and socio-economic rehabilitation of persons affected with leprosy. 36 NGOs conducting re-constructive surgeries for disability correction in leprosy affected persons are also supported by ILEP (1).

Non Government Organizations have been involved in the programme for many decades and have provided valuable contribution in reducing the burden of leprosy. Presently, 43 NGOs are getting grant-in-aid from Government of India under SET scheme. NGOs serve in remote, inaccessible areas, urban slums, industrial/labour population and other marginalized population groups. IEC, prevention of disability, case detection and referral, and follow-up for treatments completion are some important activities taken up by NGOs (1).

The leprosy scene in India is passing through an important phase of transition – from a high burden country of leprosy to a relatively low burden country, from a partially vertical programme to a more integrated one, from a programme aimed at increase in cover for leprosy services to one of sustaining quality services, and from centralization to decentralization (10).

Recently WHO has announced "enhanced global strategy" for further reducing the disease burden due to leprosy (2011–2015). Please refer to page 315 for details.
REVISED NATIONAL TUBERCULOSIS CONTROL PROGRAMME

National Tuberculosis Programme (NTP) has been in operation since 1962. However, the treatment success rates were unacceptably low and the death and default rates remained high. Spread of multidrug resistant TB was threatening to further worsen the situation. In view of this, in 1992 Government of India along with WHO and SIDA reviewed the TB situation in the country and came up with following conclusions:

- NTP, though technically sound, suffered from managerial weaknesses
- Inadequate funding,
- Over-reliance on X-ray for diagnosis
- Frequent interrupted supplies of drugs
- Low rates of treatment completion

In 1993, in order to overcome these lacunae, the Government of India decided to give a new thrust to TB control activities by revitalizing the NTP with the assistance from international agencies. The Revised National TB Control Programme (RNTCP) thus formulated, adopted the internationally recommended Directly Observed Treatment Short-course (DOTS) strategy, as the most systematic and cost-effective approach to revitalize the TB control programme in India. Political and administrative commitment, to ensure the provision of organized and comprehensive TB control services was obtained. Adoption of smear microscopy for reliable and early diagnosis was introduced in a decentralized manner in the general health services. DOTS was adopted as a strategy for provision of treatment to increase the treatment completion rates. Supply of drugs was also strengthened to provide assured supply of drugs to meet the requirements of the system.

The objectives of the RNTCP are:

1. Achievement of at least 85 per cent cure rate of infectious cases of tuberculosis, through DOTS involving peripheral health functionaries; and
2. Augmentation of case finding activities through quality sputum microscopy to detect at least 70 per cent of estimated cases.

The revised strategy was introduced in the country in a phased manner as Pilot Phase I, Pilot Phase II and Pilot Phase III. By the end of 1998, only 2 percent of the total population of India was covered by RNTCP. Large-scale implementation began in late 1998. The RNTCP has expanded rapidly over the years and since March 2006, it covers the whole country. The RNTCP has now entered into its second phase in which the programme aims to consolidate the gains made to date, to widen services in terms of activities and access and to sustain the achievements. The new initiatives and the wider collaboration with other sectors aim to provide standardized treatment and diagnostic facilities to all TB patients irrespective of the health care facility from which they seek treatment. The RNTCP also envisages improved access to marginalized groups such as urban slum dwellers and tribal groups etc.

RNTCP is built upon infrastructure already established by the previous national tuberculosis programme, while incorporating the elements of the internationally recommended DOTS.

DOTS strategy adopted by Revised National TB Control Programme initially had the following five main components:

1. Political will and administrative commitment.
2. Diagnosis by quality assured sputum smear microscopy.
3. Adequate supply of quality assured short course chemotherapy drugs.
5. Systematic monitoring and accountability.

In 2006, STOP TB strategy was announced by WHO and adopted by RNTCP. The components are as follows:

- Pursuing quality DOTS - expansion and enhancement.
- Addressing TB/HIV and MDR-TB.
- Contributing to health system strengthening.
- Engaging all service providers.
- Empowering patients and communities.
- Enabling and promoting research (diagnosis, treatment, vaccine).

Many of the initiatives like developing and piloting the feasibility of National Airborne Infection Control Guidelines, developing and piloting strategy for Practical Approach to Lung Health are the examples of initiatives taken by RNTCP under the comprehensive strategy of STOP TB (11).

ORGANIZATION

1. The profile of RNTCP in a state is as follows:
   - State Tuberculosis Office - State Tuberculosis Officer
   - State Tuberculosis Training and Demonstration Centre - State Tuberculosis Officer
   - District Tuberculosis Centre - Medical Officer - TB Control
   - Tuberculosis Unit - Senior Treatment Supervisor
   - Microscopy Centres, Treatment Centres - Senior TB Laboratory Supervisor
   - DOTS Providers

LABORATORY NETWORK

Quality Assured Laboratory services : RNTCP has established a nationwide laboratory network, encompassing over 13,309 designated sputum microscopy centres (DMCs), which are being supervised by inter-mediate reference laboratories (IBL) at state level, and national reference laboratories (NRL) and central TB division at the National level. RNTCP aims to consolidate the laboratory network into a well-organized one, with a defined hierarchy for carrying out sputum microscopy with external quality assessment (EQA). The structure of laboratory network at different levels is as shown in Fig. 2.

- National Reference Laboratories (NRL) : The six NRLs under the programme are National Institute for Research in Tuberculosis (NIRT) Chennai, National Tuberculosis Institute (NTI), Bangalore, Lala Ram Sagar Institute of Tuberculosis and Respiratory diseases (LRSI), Delhi and JALMA Institute, Agra; Regional Medical Research Centre, Bhuj, Ahmedabad; and Regional Medical Research Centre, Bhopal (12). The NRLs work closely with the IRLs, monitor and

Supervise the IRL's activities and also undertake periodic
training for the IRL staff in EQA, Culture & DST activities.

Three microbiologists and four laboratory technicians have been provided by the RNTCP on contractual basis to each
NRL for supervision and monitoring of laboratory
activities. The NRL microbiologist and laboratory
supervisor/technician visits each assigned state at least once
a year for 2 to 3 days as a part of on-site evaluation under the
RNTCP EQA protocol.

Intermediate reference laboratory (IRL) : One IRL has
been designated in the state tuberculosis control and
demonstration centres (STDC)/public health laboratory/
medical college of the respective state. The functions of IRL
are supervision and monitoring of EQA activities,
mycobacterial culture and DST, and also drug resistance
surveillance (DRS) in selected states. The IRL ensures the
proficiency of staff in performing smear microscopy activities
by providing technical training to district and sub-
district laboratory technicians and senior TB laboratory
supervisors (STLSs). The IRLs undertake on-site evaluation and
panel testing to each district in the state, as least once a
year.

Designated microscopy centre (DMC) : The first
peripheral laboratory under the RNTCP network is the DMC
which serves a population of around 100,000 (50,000 in
tribal and hilly areas). Currently all the districts in the
country are implementing EQA. For quality improvement
purposes, the NRL on-site evaluation (OSE) recommendations
are made to IRLs and districts are discussed in the
RNTCP laboratory committee meetings, quarterly at CTD.
Quality improvement workshops for the state level TB
officers and laboratory managers are conducted at NRLs
based on the observations of the NRL-GSEs. These
workshops focus on issues such as human resources,
training, AMC for binocular microscopes, quality
specifications forZN stains, RSMC and coding issues, bio-medical waste disposal, infection control
measures etc.

The Quality Assurance activities include:

- On site evaluation,
- Panel testing and
- Random blinded rechecking.

Culture and DST laboratories (C & DST) (12)

In addition to IRLs, the RNTCP also involves the
microbiology department of medical colleges for providing
diagnostic services for the drug resistant TB, extra-
 pulmonary TB and researh. There are 51 RNTCP certified
C & DST laboratories in the country which includes
laboratories from public sector (IRLS and medical colleges,
private sector and operated by NGOs).

Solid culture certification : The RNTCP has certified
37 laboratories for solid C & DST. These include 4 NRLs,
18 IRLs, 6 medical colleges, 3 NGOs, 4 ICMR institutes
and 2 private laboratories.

Liquid culture certification : The RNTCP has certified 12
laboratories for liquid culture, which include 4 NRLs, 4 IRLs,
one NGO laboratory and 2 private laboratories.

Line Probe Assay (LPA) : The LPA is a molecular
diagnostic test, which can provide the DST results within
one day. The RNTCP has adopted the policy for rapid
diagnosis of MDR-TB by LPA. As on December 2013, about
41 laboratories have been certified by RNTCP, these include
4 NRLs, 24 IRLs, 8 medical colleges, 4 NGO laboratories
and one private medical college.

The molecular laboratories are equipped with clean room
facility and GT BLOT machines to perform up to 90 tests per
day for the diagnosis of MDR-TB.

Second line DST (SSL) : As on December 2013 five
laboratories which includes 3 NRLs, one IRL and one NGO
laboratory are performing second line DST in solid and
liquid culture.

RNTCP endorsed TB diagnostics (1)

1. Smear microscopy for acid fast bacilli.
   a. Sputum smear stained with Ziehl-Neelsen staining; or
   b. Fluorescence stains and examined under direct or indirect microscopy with or without LED.

2. Culture
   a. Solid (Lowenstein Jensen) media; or
   b. Liquid media (Middle Brook) using manual semi-
   -automatic or automatic machines, e.g., Bactec, MGIT
   etc.

3. Rapid diagnostic molecular test
   a. Conventional PCR based Line Probe Assay for MTB
   complex; or
   b. Real-time PCR based Nucleic Acid Amplification Test
   NAAT for MTB complex, e.g. GeneXpert.

New Initiatives

1. The RNTCP has completed the feasibility study
   of introducing GeneXpert in RNTCP in 18 Tuberculosis Units in
   12 states. RNTCP is currently using CB NAAT for the
diagnosis of tuberculosis and MDR-TB in high risk population like HIV positive and paediatric groups (12).

2. Nikshay: TB surveillance using case based web based IT system (12)

Central TB Division in collaboration with National Informatics Centre has undertaken the initiative to develop a case based web based application named Nikshay. This software was launched in May 2012 and has following functional components:

- Register management
- User details
- TB Patient registration and details of diagnosis, DOT provider, HIV status, follow-up, contact tracing, outcomes.
- Details of solid and liquid culture and DST, LPA, CBNAAT details.
- DR-TB patient registration with details.
- Referral and transfer of patient.
- Private health facility registration and TB notification.
- Mobile application for TB notification.
- SMS alerts to patients or registration.
- SMS alerts to programme officers.
- Automated periodic reports
  a. Case finding
  b. SpuM conversion
  c. Treatment outcome.

3. TB Notification

In order to ensure proper diagnosis and management of TB cases, and to reduce TB transmission and the emergence and spread of MDR-TB, it is essential to have comprehensive information of all TB cases. According to the Government of India notification dated 7th May 2012, it is now mandatory for all healthcare providers to notify every TB case to local authorities i.e. District Health Officer/Chief Medical Officer of a district and Municipal health officer, every month in a given format (14).

At present, 57,000 health facilities have been registered and 35,000 patients have been notified (1).

4. Ban on TB Serology

The serological tests are based or antibody response, which is highly variable in TB and may reflect remote infection rather than active disease. Currently available serological tests are having poor specificity and should not be used for the diagnosis of pulmonary or extra-pulmonary TB. Their import, manufacturing, sale, distribution and use is banned by the Government of India (12).

Initiation of treatment

Under the RNTCP active case finding is not pursued. Case finding is passive. Patients presenting themselves with symptoms suspicious of tuberculosis are screened through 2 sputum smear examinations. Sputum microscopic examination is done in designated RNTCP microscopy centres. They are located either in the CHC, PHC, Taluka Hospitals or in the TB dispensary. Each centre has a skilled technician to ensure quality control, a senior TB laboratory supervisor is appointed for every 5 microscopy centres. The senior TB laboratory supervisor rechecks all the positive slides and 10 per cent of the negative slides of these microscopy centres. Thus the error in diagnosing a patient is minimized. It is essential to examine 2 sputum specimens of each patient before a conclusive diagnosis can be made. One sputum sample is not sufficient for diagnosis as the chance of detecting smear positive case is only 80 per cent. Sputum microscopy not only confirms the diagnosis, but also indicates the degree of infectivity and response to treatment. Fig. 3 shows the criteria for diagnosis and initiation of treatment.

All patients are provided short-course chemotherapy free of charge. During the intensive phase of chemotherapy all the drugs are administered under direct supervision called Direct Observed Therapy Short-term (DOTS). DOTS is a community based tuberculosis treatment and care strategy which combines the benefits of supervised treatment, and the benefits of community based care and support. It ensures high cure rates through its three components: appropriate medical treatment, supervision and motivation by a health or non-health worker, and monitoring of disease status by the health services. DOTS is given by peripheral health staff such as MPWs, or through voluntary workers such as teachers, anganwadi workers, desk, ex-patients, social workers etc. They are known as DOT 'Agent' and paid incentive/honourarium of Rs 150 per patient completing the treatment.

Cough for 2 Weeks or more

- 2 Sputum smears
  - 1 or 2 Positive
    - Antibiotics 10-14 days
    - Repeat sputum examination
    - 1 or 2 Positive
  - 2 Negative
    - X-ray
    - Negative for TB
    - Positive
      - Anti-TB Treatment
      - Anti-TB Treatment

FIG. 3: Diagnosis of tuberculosis in RNTCP
The drugs are supplied in patient-wise boxes containing the full course of treatment, and packaged in blister packs. For the intensive phase, each blister pack contains one day’s medication. For the continuation phase, each blister pack contains one week’s supply of medication. The combination drugs for extension of intensive phase are supplied separately. The boxes are coloured according to the category of the regimen, red for category 1 patients, blue for category II patients.

Paediatric tuberculosis (12)
Please refer to page 295 for details.

Drug resistance surveillance (DRS) under RNTCP (11)

The prevalence of drug resistance to TB can be taken as an indicator of the effectiveness of the TB control activities over a period of time and, therefore, RNTCP has taken steps to measure this important indicator.

The aim of DRS is to determine the prevalence of antimycobacterial drug resistance among new sputum smear positive pulmonary tuberculosis (PTB) patients, and also amongst previously treated sputum smear positive PTB patients. Drug-resistant TB has frequently been ecountered in India, and its presence has been known virtually from the time anti-TB drugs were introduced for the treatment of TB.

To obtain a more precise estimate of Multi-Drug Resistant TB (MDR-TB) burden in the country, RNTCP carried our drug resistance surveillance (DRS) surveys in accordance with global guidelines in selected states. The results of these surveys indicate prevalence of MDR-TB to be about 2.2 (1.5-2.6) per cent in new cases and 11 (11-19) per cent in retreatment cases (16).

PROGRAMMATIC MANAGEMENT OF DRUG RESISTANT TB (PMDT)

DOTS-Plus

The PMDT services for quality diagnosis and treatment of drug resistant TB cases were initiated in 2007 in Gujarat and Madhya Pradesh. These services since then have been scaled up and currently these services are available across the country from March 2013. As of 2013, about 20,000 (17,000-24,000) among new pulmonary TB cases and 41,000 retreatment cases of MDR-TB have been reported in India, and of these 32,922 confirmed cases were put on standard regimen for MDR-TB under RNTCP (16).

For full details about the DOTS-Plus programme and patient regimen please refer to page 190 and 199.

TB-HIV coordination (15)

Since the advent of the collaborative efforts in 2001, TB-HIV activities have evolved to cover most of the recommendations as per the latest WHO policy statement issued in 2012. In 2007, the first national framework for joint TB-HIV collaborative activities was developed which endorsed a differential strategy reflective of the heterogeneity of TB-HIV epidemics. Coordinated TB-HIV interventions were implemented including establishment of a coordinating body at national and state level, dedicated human resources, integration of surveillance, joint monitoring and evaluation, capacity building and operational research.

The implementation of collaborative TB/HIV activities are as follows:

1. Intensified TB case finding has been implemented nationwide at all HIV testing centres (known as integrated counselling and testing centres, or ICTCs), and has now been extended to all ART centres.

2. HIV testing of TB patients is now routine through provider initiated testing and counselling (PITC), implemented in all states with the intensified TB-HIV package.

3. Persons living with HIV positive are eligible free HIV care at a network of antiretroviral treatment (ART) centres. ART centres are located in medical colleges, mainly staffed and operated by the state AIDS control societies, and a few are situated within the facilities of private or NGO partners. As of December 2012, there were 410 ART centres operating in the country, 91 link ART centres and 158 link ART centres. Ten Regional Centres of Excellence provide second-line ART services for PLHIV, and 24 centres provide second line ART (ART plus centres). HIV-infected TB patients who are on protease inhibitor-based second line ART are getting rifabutin-based TB treatment in place of Rifampicin.

4. Policy decision has been taken by National Technical Working Group on TB/HIV collaborative activities (NTWG on TB/HIV) to expand coverage of whole blood finger prick HIV screening test at all DMC without a stand-alone or F-ICTC.

5. Provider initiated HIV testing and counselling (PITC) among presumptive TB cases (TB suspects) is now a policy.

a. In high HIV prevalence states/settings – The implementation will be done in a phased manner, starting with high prevalent states and then in A and B category districts in rest of the country.

b. In low HIV prevalent states/settings – HIV testing among presumptive TB cases should be routinely implemented in the age-group of 20-44 years in low HIV prevalent districts (C & D) at places where there are co-located TB and HIV testing facilities.

6. Intensified case finding activities to be specifically monitored among HIV infected pregnant women and children living with HIV.

7. The National AIDS Control Programme (NACP) and RNTCP have taken the policy decision to adopt isoniazid prophylaxis therapy (IPT) as a strategy for prevention of TB among PLHIV. The implementation will be in a phased manner.

8. The RNTCP has prioritised presumptively TB cases among people living with HIV for diagnosis of TB and Rifampicin resistance with rapid diagnostic tools having high sensitivity e.g. Xpert MTB/RIF.

The treatment guidelines are discussed in detail on page 201.

Tuberculosis in pregnancy

Please refer to page 196 for details.

National Strategic Plan (2012–2017)

With progress in achieving objectives in the 11th Five Year Plan and defining newer targets of universal access to TB care, newer strategies have been developed as a comprehensive National Strategic Plan under the 12th Five
Year Plan. The following thrust areas were identified (15):
- Strengthening and improving the quality of basic DOTS and NRNM.
- Further strengthen and align with health system under NRNM.
- Deploying improved rapid diagnosis at the field level.
- Expand efforts to engage all care providers.
- Strengthen urban TB control.
- Expand diagnosis and treatment of drug resistant TB.
- Improve communication and outreach.
- Promote research for development and implementation of improved tools and strategies.

**Strategic vision to move towards universal access**

The vision of the Government of India is for a "TB-free India" with reduction of the burden of the disease until it is no longer a major public health problem. To achieve this vision, the programme has adopted the new objective of Universal Access for quality diagnosis and treatment for all TB patients in the community. This entails sustaining the achievements of the programme to date, and extending the reach and quality of services to all persons diagnosed with TB.

The objectives of the programme proposed in the plan are (15):

- Early detection and treatment of at least 90% of estimated all type of TB cases in the community, including drug resistant and HIV associated TB.
- Successful treatment of at least 90% of all TB patients, and at least 85% of previously-treated TB patients.
- Reduction in default rate of new TB cases to less than 5% and re-treatment TB cases to less than 10%.
- Initial screening of all re-treatment smear-positive till 2015, and all smear positive TB patients by year 2017 for drug-resistant TB and provision of treatment services for MDR-TB patients.
- Offer of HIV counselling and testing for all TB patients and linking HIV-infected TB patients to HIV care and support.
- Extend RNTCP services to patients diagnosed and treated in the private sector.

**Targets**

The targets proposed are:

1. Detection and treatment of about 87 lakh tuberculosis patients during the 12th Five Year Plan.
2. Detection and treatment of at least 2 lakh MDR-TB patients during the 12th Five Year Plan.
3. Reduction in delay in diagnosis and treatment of all types of TB cases.
4. Increase in access to services to marginalized and hard to reach populations, and high risk and vulnerable groups.

**Achievements of RNTCP**

The RNTCP covers the whole country since March 2006. Phase II of the RNTCP has been launched in the country from 1st October 2006. The treatment success rate has more than doubled from 25 per cent in 1998 to 84 per cent in 2013. Death rate has been brought down seven folds from 29 per cent to 4 per cent. 662 DTCs, 2,698 TB Units and 13,209 DMCs are functional in the country. The programme involves more than 2,708 NGOs, more than 13,311 private practitioners, over 319 medical colleges and more than 159 corporate health facilities. More than 13,309 peripheral laboratories/Designated Microscopy Centres have been established. More than 6 nos public health care providers have been trained under the programme. Master trainers on TB/HIV have been trained on TB/HIV related issues in 12 states. More than 16 million patients have been initiated in treatment, saving almost 2.5 million lives. Four urban DOTS projects have also been launched to solve the problems of inaccessibility of TB care faced by urban poor utilizing GFATM (Global Fund to fight AIDS, TB & Malaria) support in Mumbai, Hyderabad, Varanasi and Chennai.

The laboratory services provided are as follows (16):

**Laboratories 2013**

- Sputum (per 100,000 population): 1.0
- Culture (per 5 million population): 0.2
- Drug-susceptibility testing (per 5 million population): 0.2
- Sputum performances: Xpert MTB/RIF: 54

Is second-line drug susceptibility testing available? Yes, in country

For the incidence rate, prevalence rate and treatment outcome details, please refer to page 177.

**Financial resources**

The programme is being assisted by the World Bank and the Department for International Development (DFID) of the UK. In addition, the RNTCP is supported by the Global TB Drug Facility (GTDF). The Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM), the United States Agency for International Development (USAID) and DANIDA. Countries of India provide 100 per cent of their share in-aid to the implementing agencies i.e., states/UTs, besides free drugs. The states are expected to use the existing infrastructure and also to provide some manpower resources.

**NATIONAL AIDS CONTROL PROGRAMME**

National AIDS Control Programme was launched in India in the year 1987. The Ministry of Health and Family Welfare has set up National AIDS Control Organization (NACO) as a separate wing to implement and closely monitor the various components of the programme. The aim of the programme is to prevent further transmission of HIV, to decrease morbidity and mortality associated with HIV infection and to minimize the socio-economic impact resulting from HIV infection.

The milestones of the programme are summarized as follows (17):

1986 - First case of HIV detected.
- AIDS Task Force set up by the ICMR.
- National AIDS Committee established under the Ministry of Health.
1990 - Medium Term Plan launched for four states and the four metros.
1992 - NACP-I launched to slow down the spread of HIV infection.
- National AIDS Control Board constituted.
- NACO set-up.
1999 - NACP-II begins, focusing on behavioural change, increased decentralization and NGO involvement.
- State AIDS Control Societies established.
2004 – Anti-retroviral treatment initiated.
2006 – National Council on AIDS constituted under chairmanship of the Prime Minister.
- National Policy on Paediatric ART formulated.
The national strategy has the following components:
- establishment of surveillance centres to cover the whole country;
- identification of high-risk group and their screening;
- issuing specific guidelines for management of detected cases and their follow-up;
- formulating guidelines for blood bank, blood product manufacturers, blood donors and dialysis units; information, education, and communication activities by involving mass media and research for reduction of personal and social impact of the disease; control of sexually transmitted diseases; and condom programme.

The package of services under NACP-IV are as follows [15]:

1. Prevention services
- Targeted interventions for high-risk groups (female sex workers, men who have sex with men, transgenders/ hijras, injecting drug users) and bridge population (truckers and migrants).
- Needle-syringe exchange programme and opioid substitution therapy for IDUs.
- Prevention interventions for migrant population at source, transit and destination.
- Link worker scheme for HRGs and vulnerable population in rural areas.
- Prevention and control of sexually transmitted infections/reproductive tract infections.
- Blood safety.
- HIV counselling and testing services.
- Prevention of parent to child transmission.
- Condom promotion.
- Information, education and communication and behaviour change communication (RCC).
- Social mobilization, youth interventions and adolescence education programme.
- Mainstreaming HIV/AIDS response.
- Work place interventions.

2. Care, support and treatment services
- Laboratory services for CD4 testing and other investigations.
- Free first-line and second-line Anti-Retroviral Therapy (ART) through ART centres and Link ART Centres (LACs), Centres of Excellence (CoE) and ART plus.
- Paediatric ART for children.
- Early infant diagnosis for HIV exposed infants and children below 18 months.
- Nutritional and psycho-social support through Care and Support Centres (CSC).
- HIV/TB coordination (cross-referral, detection and treatment of co-infections).
- cascade of defaulting infections.
- Drop-in centres for PLHIV networks.

Country scenario
Based on sentinel surveillance data, the HIV prevalence in adult population can be broadly classified into three groups of States/UTs in the country.

Group I Moderate Prevalence States: includes states of Maharashtra, Tamil Nadu, Karnataka, Andhra Pradesh, Manipur and Nagaland where the HIV infection has crossed 5% or more among high risk groups but the infection is below 1% in antenatal women.

Group II Low Prevalence States: includes remaining states where the HIV infection in any of the high risk groups is still below 5% and ≤ 1% less than 1% among antenatal women.

Categories of Districts

In the country, the districts have been classified according to the epidemiological and vulnerability criteria using the sentinel surveillance data for the last 3 years (Table 5).

HIV surveillance

Different types of surveillance activities are being carried out in the country to detect the spread of the disease and to make appropriate strategy for prevention and control viz., area specific targeted intervention and best practice approach. The types of surveillance are: (a) HIV Sentinel Surveillance, (b) HIV Sero-Surveillance, (c) AIDS Case Surveillance, (d) STD Surveillance, (e) Behavioural Surveillance, and (f) Integration with surveillance of other diseases like tuberculosis etc.

HIV SENTINEL SURVEILLANCE: After the establishment of the fact that HIV infection is present in wide geographic areas, the aim of surveillance was redefined to monitor the trends of HIV infection. The objectives of the surveillance are as follows (20):

1. To determine the level of HIV infection among general population as well as high-risk groups in different states;
2. To understand the trends of HIV epidemic among general population as well as high-risk groups in different states;
3. To understand the geographical spread of HIV infection and to identify emerging pockets;
4. To provide information for prioritization of programme resources and evaluation of programme impact; and
5. To estimate HIV prevalence and HIV burden in the country.

The objective of the surveillance is best achieved by annual cross-sectional survey of the risk group, in the same place over few years by unlinked anonymous serological testing procedures by two ERS (i.e., when HIV testing is carried out without identification of name of samples collected for other purposes e.g., VDRL in STD clinics. The objective of surveillance may be fulfilled in this example whereas the positive person is not identified). The number of samples to be screened must represent the risk group under study and the sample size is determined accordingly. Clinical based approach for such collection has many advantages including the procedure for collection of samples which should be carried out on the above lines to avoid "selection bias" and "participation bias."

To start with, the HIV sentinel surveillance for HIV was taken up from 1994 in 55 sentinel sites attached to the existing surveillance centres and were increased to 180 in 1998. While the number of the high risk groups of HIV sentinel sites were increased every year, with change of sites, these 180 sites have remained consistent. Inclusion of data from high-risk population through targeted intervention sites and the additional sub-set of rural samples through ante-natal clinics are the key features of HIV sentinel surveillance. Pregnant women attending antenatal clinics are taken as proxy for general population. The number of HIV sentinel surveillance sites for different population groups during 2008-09 and 2010-11 are as shown in Table 6.

Counselling and HIV testing services

The Basic Service Division of the department of AIDS control provides HIV counselling and testing services for HIV infection. The national programme is offering these services since 1997 with the goal to identify as many people living with HIV as early as possible (after acquiring the HIV infection), and linking them appropriately and in a timely manner to prevention, care and treatment services. The introduction of ART services for people living with HIV/AIDS in 2004, gave a major boost to counselling and testing services in India. The HIV counselling and testing services include the following components:

1. Integrated Counselling and Testing Centres (ICTC)
2. Prevention of parent-to-child transmission of HIV (PPTCT)
3. HIV/tuberculosis collaborative activities.

INTEGRATED COUNSELLING AND TESTING CENTRES

Diverse models of HIV counselling and testing services are available to increase access to HIV diagnosis, these include testing services in health care facilities, standalone sites and community-based approaches at various levels of public health systems in India from state, district, sub-district and village/community levels as depicted in Fig. 4.

1. Fixed facility ICTCs are located within an existing healthcare facility/hospital/health centre, and are of two types - Standalone and Facility-integrated counselling and testing centres.
   a. Standalone ICTC (SA-ICTC): The client load is high in these centres, with flexible working hours and a technician who provide HIV counselling and testing services. SA-ICTC are located in medical colleges, RTH and other mid-level health care providers, NGOs, etc.
   b. Facility-integrated counselling and testing centres (F-ICTCs): Considering the need for rapid scale-up and sustainability of HIV counselling and testing services, F-ICTCs were established in private facilities for profit/not-for-profit hospitals, laboratories, non-governmental organizations (NGOs), and have been supported by DAC-SACs in supply of rapid HIV testing kits, training of existing staff, quality assurance, supply of protective kits and prophylactic drugs for post-exposure prophylaxis for staff, supply of IEC materials such as flip charts, posters etc. required for ICTC.

2. Mobile ICTC: Mobile counselling and testing centres are a van with a room to conduct general examination, counselling and space for collection and processing blood samples by a team of para-medical healthcare providers (a health education/ANM, counsellor and laboratory technican). Mobile ICTC are set up as temporary clinics in hard-to-reach remote health care facilities, and provide a wide range of services like counselling and testing services for HIV, syngromic management of STI/RTI and other minor ailments, along with regular health check-ups, antenatal, immunisation services etc.

Community based HIV screening: In order to offer HIV testing to every pregnant woman in the country, as to detect all HIV positive pregnant women and eradicate the transmission of HIV from parent to child, the community-based HIV screening is conducted by frontline health workers (Auxiliary Nurse Midwives) at the sub-centre level.

PREVENTION OF PARENT-TO-CHILD TRANSMISSION OF HIV

The prevention of parent-to-child transmission of HIV/AIDS (PPTCT) programme was started in the country in the year 2002. Currently, there are more than 15,000 ICTCs in the country which offer PPTCT services to pregnant women.

The aim of the PPTCT programme is to offer HIV testing to every pregnant woman (universal coverage) in the country, so as to cover all estimated HIV positive pregnant women and eliminate transmission of HIV from mother-to-child.

In India, PPTCT interventions under NACP was started in 2002, using SD-NVP prophylaxis for HIV positive pregnant women during labour and also for her newborn child immediately after birth. With the department of AIDS control adopting "Option B" of the World Health Organization recommendations (2010), India has also transitioned from the single dose Nevirapine strategy to that of multi-dose ARV prophylaxis from September 2012. This strategy was executed in the three southern high HIV
Prevention

1. Isoniazid preventive treatment
2. Airborne infection control
3. Awareness generation

Early detection of TB/HIV

1. 100% coverage of PTC in TB patients
2. PTC in presumptive TB cases
3. Rapid diagnostics for detection of TB and DIS-TB in PLHIV
4. ICF activities at all HIV settings – ICTC, ART, LAC and TJ settings

Prompt treatment of TB/HIV

1. Early initiation of ART
2. Prompt initiation of TB treatment

Management of special TB/HIV cases

1. TB/HIV patients on PI based ARV
2. TB/HIV in children
3. TB/HIV pregnant women
4. Drug resistant TB/HIV

FIG. 5

Activities to reduce HIV–TB mortality

Source: (23)

prevalence states of Andhra Pradesh, Karnataka and Tamil Nadu. The national strategic plan for PPTCT services using multi-drug ARVs in India was developed in May-June 2013 for nationwide implementation in a phased manner. Based on the new WHO guidelines (June 2013) and on the suggestions from the technical resource groups during December 2013, department of AIDS control has decided to initiate lifelong ART (using the triple drug regimen) for all pregnant and breast-feeding women living with HIV, regardless of CD4 count or WHO clinical stage, both for their own health and to prevent vertical HIV transmission, and for additional HIV prevention benefits.

The PPTCT services provide access to all pregnant women for HIV diagnostic, prevention, care and treatment services. As such, the key goal is to ensure the integrated PPTCT service delivery with the existing Reproductive and Child Health (RCH) programme.

The essential package of PPTCT services in India are as follows (22) :
1. Routine offer of HIV counselling and testing to all pregnant women enrolled into antenatal care, with an ‘opt out’ option.
2. Ensuring involvement of spouse and other family members, and move from an “ANC-Centric” to a “Family-Centric” approach.
3. Provision of life-long ART (TDF+3TC+EFV) to all pregnant and breast-feeding HIV infected women, regardless of CD4 count and clinical stage of HIV progression.
4. Promotion of institutional deliveries of all HIV infected pregnant women.
5. Provision of care for associated conditions (STI/RTI, TB and other opportunistic infections).
6. Provision of nutrition, counselling and psychosocial support for HIV infected pregnant women.
7. Provision of counselling and support for initiation of exclusive breast-feeds within 24 hour of delivery as the preferred option and continued for 6 months.
8. Follow up of ARV prophylaxis to infants from birth up to a minimum of 6 months.
9. Integrating follow-up of HIV-exposed infants into routine healthcare services including immunization.
10. Ensuring initiation of Co-trimoxazole Prophylactic Therapy (CPT) and Early Infant Diagnosis (EID) using HIV/DNA PCR at 6 weeks of age onwards, as per the EID guidelines.
11. Strengthening community follow-up and outreach through local community networks to support HIV-positive pregnant women and their families.

HIV TESTING OF TB PATIENTS

Detection of HIV by offering HIV tests to diagnosed TB patients is being implemented by NACP and RNTCP jointly since 2007–08. States with high HIV prevalence cover about 90% TB patients for HIV testing, but case fatality rate among HIV infected TB cases remains 13–14%, as compared to less than 4% in HIV negative TB cases, indicating delayed detection of HIV/TB inspite of good coverage. Therefore, NACP and RNTCP have jointly decided to offer HIV testing upstream during evaluation of patients for TB when they present with TB symptoms. This activity is expected to expedite detection of HIV within 2–4 weeks of TB positivity, leading to early linkage to HIV treatment and hence reduction in mortality. HIV testing in presumptive TB cases was rolled out in India in October 2012 in Karnataka, followed by Maharashtra, Andhra Pradesh and Tamil Nadu. It is planned to extend this strategy to high HIV prevalence districts i.e. A and B category districts. Further the NTWG has recommended implementation of this strategy among 25–54 years age group in the rest of the country.

The four pronged strategy for HIV–TB coordination activity to reduce mortality are summarised in Fig. 5.
Care, support and treatment

The care, support and treatment (CST) component of NACP aims to provide comprehensive services to people living with HIV (PLHIV) with respect to free Anti-Retroviral Therapy (ART), psychosocial support, prevention and treatment of opportunistic infections (OI) including tuberculosis, and facilitating home-based care and impact mitigation.

CST services are provided through ART centres established by DAC in health facilities across the country. These are linked to Centres of Excellence (CoE) and ART-Plus centres at selected institutions, while some of the services have been decentralized through Link ART Centres (LAC). ART centres are also linked to ICTCs, STI clinics, PPTCT services and other clinical departments in the institutions of their location, as well as with the Revised National Tuberculosis Programme (RNTCP), in order to ensure proper management of TB-HIV co-infected patients. Fig 6 gives a graphic view of this service delivery model.

![Model of HIV treatment services](image)

**FIG. 6**

As of March 2014, about 425 ART centres, 870 link ART centres, 19 centres of excellence, 7 paediatric centres of excellence, 37 ART Plus centres and 224 care and support centres are functioning in the country (22).

**Services provided**

1. **First-line ART:** First-line ART is provided free of cost to all eligible PLHIV through ART centres. Positive cases referred by ICTCs are registered in ART centres for pre-ART and ART services. The assessment for eligibility for ART is done through clinical examination and CD4 count. Patients are also provided counselling on treatment adherence, nutrition, positive prevention and positive living. Follow-up of patients on ART is done by assessing drug adherence, regularity of visits, periodic examination and CD4 count (every six months). Treatment for opportunistic infections is also provided through ART centres. Till March 2014, 7.68 lakh PLHIV were on first-line ART.

2. **Alternative first-line ART:** It has been observed that a small number of patients initiated on first-line ART experience acute/chronic toxicity/intolerance to first-line ARV drugs, thus necessitating change of ARV drugs to alternative first-line drugs. Presently, the provision of alternative first-line ART is done through Homoeo Centre of Excellence and ART-Plus centres across the country.

3. **Second-line ART:** The second-line ART began in January 2006 at two sites – G.M. Medical and JJ Hospital, Mumbai on a pilot basis, and was then further expanded to the other CoEs in January 2009. Further decentralization of second-line ART was done through capacitating and upgrading some well-functioning ART centres as ‘ART-Plus Centres’. Till March 2014, 8,897 patients were receiving second-line drugs at CoEs and ART-Plus centres. All ART centres are linked to CoE/ART-Plus centres. For the evaluation of patients for initiation on second-line and alternate first-line ART, a State AIDS Clinical Expert Panel (SACEP) has been constituted by DAC at all CoEs and ART-Plus centres. This panel meets once in a week for taking decisions on patients referred to them with treatment failure/major side effects.

**National paediatric HIV/AIDS initiative:** The national paediatric HIV/AIDS initiative was launched on 30 November 2006. Till March 2014, nearly 1,06,824 children living with HIV/AIDS (CLHIV) were registered in HIV care at ART centres, of whom 42,015 were receiving free ART. Paediatric formulations of ARV drugs are available at all ART centres.

**Paediatric second-line ART:** While the first-line therapy is efficacious, certain proportion of children do show evidence of failure. There is not much data available on the failure rate of Nevirapine-based ART in children. However, WHO estimates that the average switch rate from first to second-line ART is 2-3% per year for adults. It is likely that similar rates are acceptable for children as well. Currently, second-line ART for children has been made available at all CoE and ART-Plus centres.

**Early infant diagnosis:** In order to promote confirmatory diagnosis for HIV exposed children, a programme on Early Infant Diagnosis (EID) was launched by DAC. All children with HIV infection confirmed through EID have been linked to ART services.

**TARGETED INTERVENTIONS FOR HIGH RISK GROUPS:** The main objective of targeted interventions (TI) is to improve health-seeking behaviour of high risk groups (HRG) and reduce their risk of acquiring sexually transmitted infections (STI) and HIV infections. High risk groups under TI include female sex workers (FSW), men who have sex with men (MSM), transgenders (TG)/hijras and injecting drug users (IDU), and bridge populations include high risk behaviour migrants and long distance truckers. Targeted interventions provide the information, means and skills needed to prevent HIV transmission and improve their access to care, support and treatment services. These programmes also focus on improving sexual and reproductive health and general health of high-risk population.

The services offered through targeted interventions include:
- Detection and treatment for sexually transmitted infections
- Condom distribution (except in TIs for bridge population)
- Condom promotion through social marketing (for HRG and bridge population)
- Behavioural communication
- Creating an enabling environment with community involvement and participation
- Linkages with care and support services for HIV positive HRGs
- Community organization and ownership building
- Specific interventions for IDUs
  - Distribution of clean needles and syringes
  - Access prevention and management
  - Opioïd substitution therapy
- Linkage with detoxification/rehabilitation services
- Specific interventions for MSM/TGs
- Provision of lubricants
- Specific interventions for TG/hija populations
- Provision of project-based STI clinics

Link worker scheme: The link worker scheme is a community-based outreach strategy to address HIV prevention and care needs of HRG and vulnerable population in rural areas. The specific objectives of the scheme include reaching out to these groups with information and knowledge on prevention and risk reduction of HIV and STI, condom promotion and distribution, providing referral and follow-up linkages for various services. It includes counselling, testing and treatment of STI and opportunistic infections through link workers, creating an enabling environment for PLHIV and their families, and reducing stigma and discrimination against them. In partnership with various development partners, the link worker scheme has been expanded and is being implemented in 17 states covering 163 highly vulnerable districts.

Blood transfusion services: The division of blood safety has been renamed as the division of blood transfusion services. The change in nomenclature is to broaden the horizon of blood safety to include transfusion transmitted infections, immuno-hematology, quality management systems, logistics and other processes involved to improve confidence in the "safe blood".

Blood transfusion services have been considered as an integral part of the health care system. Blood Transfusion Councils have been set-up at national and state levels. Professional blood donation has been prohibited in the country since 1st January 1998. Only licensed blood banks are permitted to operate in the country and voluntary-blood donation is encouraged. The strategy is to ensure safe collection, processing, storage and distribution of blood and blood products. Zonal blood testing centres have been established to provide linkage with other blood banks affiliated to public, private and voluntary sectors. As per national blood safety policy, testing of every unit of blood is mandatory for detecting infections like HIV, hepatitis B, hepatitis C, malaria and syphilis.

Access to safe blood for the needy is the primary responsibility of NACO. It is supported by a network of 1,137 blood banks, including 258 Blood Component Separation Units (BCSU) and 34 Model Blood Banks. NACO supported the installation of BCSU and has given funds for modernization of all major blood banks at state and district levels. Besides enhancing awareness about the need to procure safe blood and blood products, NACO has supported the procurement of equipment, test kits and reagents, and in helping in the recurring expenditure of government blood banks and those run by voluntary/charitable organizations, that were modernized.

In order to ease the situation of shortage of availability of blood in the rural areas, where it is not feasible to operate a blood bank, Govt. has decided to establish blood storage centres at First Referral Units (FRUs), at sub-district levels, for wider availability of safe blood, particularly for emergency obstetric care and trauma care services.

Condom promotion: Condom promotion strategies will be strengthened through free distribution and social marketing channels, non-traditional outlets, female condoms, etc. aided by an effective communication strategy. The programme will continue to link prevention with care, support and treatment. This will promote positive prevention.

On the basis of HIV prevalence and family planning needs, the districts have been mapped and classified into four categories: (a) High prevalence of HIV and high fertility (HPHF); (b) High prevalence of HIV and low fertility (HPLF); (c) Low prevalence of HIV and low fertility (LPLF); and (d) Low prevalence of HIV and high fertility (LPFH). During 2013-14 the coverage of condom social marketing programme implementation was spread across 222 districts, i.e. 49 HPHF, 49 HPLF and 130 LPHF districts in 11 states (22).

STD CONTROL PROGRAMME: STD control is linked to HIV/AIDS control as behavioural risk in the transmission of STD and HIV are same. HIV is transmitted more easily in the presence of another STD. Hence, early diagnosis and treatment of STD is now recognized as one of the major strategies to control spread of HIV infection. The following approach is adopted for the STD control (24):

a. Management of STIs through syndromic approach (management of sexually transmitted diseases based on specific symptoms and signs and not dependent on laboratory investigations).

b. STDs among women, though highly prevalent, are suppressed because of the social stigma attached to the disease. It has, therefore, been decided to integrate services for treatment of reproductive tract infections (RTIs) and sexually transmitted diseases (STDs) at all levels of health care, Department of Family Welfare and NACO will coordinate their activities for an effective implementation of such integration. STDs Clinics at district / block level First Referral Unit (FRI) level would function as referral centres for treatment of STIs referred from peripheries. STDs clinics in all district hospitals, medical colleges and other centres would be strengthened by providing technical support, equipment, reagents and drugs. A massive orientation-training programme would be undertaken to train all the medical and paramedical workers engaged in providing STDs/RTIs services through a syndromic approach. All STDs clinics would also provide counselling services and good quality condoms to the STD patients. Services of NACOs would be utilized for providing such counselling services at the STDs clinics.

NACO has branded the STI/RTI services as "Suraksha Clinic" which has developed a communication strategy for generating demand for these services (2). PRE-PACKED STI/RTI COLOUR CODED KITS: Pre-packaged colour coded STI/RTI kits have been provided for free supply to all designated STI/RTI clinics. These kits are
being procured centrally and supplied to all State AIDS Control Societies.

The colour code is as follows (25):

Kt 1 - grey, for anal discharge, ano-rectal discharge and cervicitis.
Kt 2 - green, for vaginosis.
Kt 3 - white, for genital ulcers.
Kt 4 - blue, for genital ulcers.
Kt 5 - red, for genital ulcers.
Kt 6 - yellow, for lower abdominal pain.
Kt 7 - black, for scrotal swelling.

**Information, education and communication**

Communication is the key to generating awareness on prevention as well as motivating access to testing, treatment, care and support. With the launch of NACP-IV, the inputs is on standardizing the lessons learned during the third phase. Communication in NACP-IV is directed at:

a. To increase knowledge among general population (especially youth and women) on safe sexual behaviour;

b. To sustain behaviour change in high risk groups and bridge populations;

c. To generate demand for care, support and treatment services; and

d. To make appropriate changes in societal norms that reinforce positive attitude, beliefs and practices to reduce stigma and discrimination.

**Adolescence Education Programme:** This programme runs in secondary and senior secondary schools to built up life skills of adolescents to cope with the physical and psychological changes associated with growing up. Under the programme, 16 hour sessions are scheduled during the academic terms of class IX and XI. State AIDS control society have further adapted the modules after state level consultations with NGOs, academicians, psychologists and parent-teacher bodies. This programme is being implemented in 23 states and by March 2014, 49,000 schools have been covered.

**Red Ribbon Clubs:** The purpose of Red Ribbon Club formation in colleges is to encourage peer-to-peer messaging on HIV prevention and to provide a safe space for young people to seek clarifications of their doubts and myths surrounding HIV/AIDS. The RRCs also promote voluntary blood donation among youth.

**Year-wise targets of NACP-IV are as shown in Table 8.**

The National Programme for Control of Blindness was launched in the year 1976 as a 100 per cent centrally sponsored programme and incorporates the earlier trachoma control programme started in the year 1968. The programme was launched with the goal to reduce the prevalence of blindness from 1.4 to 0.3 per cent. As per 2006-07 survey the prevalence of blindness was 1.0 per cent (1).  

Main objectives of the programme in the 12th Five Year Plan period are:  
1. To reduce the backlog of avoidable blindness through identification and treatment of curable blind at primary, secondary and tertiary levels, based on removal of the overall burden of visual impairment in the country;  
2. Develop and strengthen the strategy of NPCB for “Eye Health for All” (eye protection/prevention) through vision care services and quality service delivery;  
3. Strengthening and upgradation of Regional Institutes of Ophthalmology (RIOs) to become centre of excellence in various subspecialties of ophthalmology and also other partners like Medical Colleges, District Hospitals, Sub-district Hospitals, Vision Centres, NGO Eye Hospitals;  
4. Strengthening the existing infrastructure facilities and developing additional human resources for providing high quality comprehensive eye care in all districts of the country;  
5. To enhance community awareness on eye care and lay stress on preventive measures;  
6. Increase and expand research for prevention of blindness and visual impairment, and  
7. To secure participation of voluntary organizations/private practitioners in delivering eye care.  

Salient features/strategies adopted to achieve the objectives are:  
1. Continued emphasis on free cataract surgery through the health care delivery system; as well as by the involvement of NGO sector and private practitioners.  
2. Emphasis on the comprehensive eye care programmes, by covering children rather than only cataract, the diabetic retinopathy, glaucoma, corneal transplantation, vitreoretinal surgery, treatment of childhood blindness etc. The growing diseases need immediate attention to eliminate avoidable blindness from the country.  
3. Reduction in the backlog of blind persons by active screening of population above 50 years age, organizing screening eye camps and transporting operable cases to fixed eye care facilities.  
4. Refractive error comprises a major part of avoidable blindness. Screening of children for identification and treatment of refractive errors and provision of free glasses to those affected and belonging to poor socio-economic strata.  
5. Coverage of underserved area for eye care services through public-private partnership.  
6. Capacity building of health personnel for improving their knowledge and skill in delivery of high quality eye services.  
7. Information Education Communication (IEC) activities for creating awareness on eye care within the community.  
8. Regional Institutes of Ophthalmology and Medical Colleges of the states to be strengthened in a phased manner with latest equipments and training of manpower so that they can be upgraded as Centres of Excellence in the regions.  
9. Randomized district hospitals to be strengthened by upgrading infrastructure, equipment and providing adequate manpower like ophthalmologists and PMOs on contract out and provide earmarked funds for basic medicines and drugs.  
10. Continuing emphasis on primary healthcare (eye care) by establishing vision centres in all PHCs with a PMO in position.  
11. Multipurpose District Mobile Ophthalmic Units for better coverage.  

To avoid duplication of work, State Ophthalmic Cell has been merged with State Blindness Control Society, and after the launch of NRHM, State Blindness Control Societies have been further merged with State Health Society. Likewise, District Blindness Control Societies have also been merged with District Health Societies. Facilities for intra-ocular lens implantation have been expanded to taluka level.  

The problem of blindness is acute in rural areas, and hence the programme has tried to expand the accessibility of eye services in these areas. At present there are 80 central mobile units attached to medical colleges and 541 district mobile units to provide eye care in mobile eye camps. These units have a vehicle, ophthalmic surgeon and other paramedical staff. Most of the cataract surgeries in rural population are conducted through these mobile camps. Primary health centres are the basic units in the rural areas.  

The findings of the survey conducted during 2001–2002, in 120 randomly selected districts of the states covered by World Bank Project shows that dependence on cataract camps has reduced, except in remote and tribal areas; involvement of PHCs/CHCs, doctor in the programme has increased; higher percentage of cataract operated persons consult the doctor at an early stage; there is an increase in demand for modern techniques like intraocular lenses and cataractless surgeries; and about 84 per cent of cataract operated persons receive two spectacles from the health facility.  

The organizational structure for the national programme for control of blindness is as shown in Fig. 7.  

SCHOOL EYE SCREENING PROGRAMME: 6–7 per cent of children aged 10–14 years have problem with their eye sight affecting their learning at school. Children are being followed by health teachers. Children expected to have refractive error are seen by ophthalmic assistants and corrective spectacles are prescribed or given free for primary school children.  

COLLECTION AND UTILIZATION OF DONATED EYES: During 2013–14 nearly 34,452 donated eyes were collected for corneal implantation (1). Hospital retrieval programme is the major strategy for collection of donated eyes, which envisage motivation of relatives of terminally ill patients, accident victims and others with severe disabilities to donate eyes. Eye donation fortnight is organized from 25th August to 9th September every year to promote eye donation/eye banking. Gujarat, Tamil Nadu, Maharashtra and Andhra Pradesh are leading states in this activity (1).  

The voluntary organizations such as Lions International and its branches, Rotary International and its branches, NSPB India etc. are encouraged to organize eye camps in
remote rural and urban areas as per guidelines, with the permission from the state authorities. They have been active in providing eye health education, preventive, rehabilitative and surgical services for control of blindness.

Community health education is a built-in component at all levels of implementation of National Blindness Control Programme. The programme also includes regular eye check-up and provision of vitamin A prophylaxis and service facilities in rural areas.

WHO assistance for prevention of blindness: This includes intra-county fellowships in corneal transplantation, vitreo-retinal surgery, lasers in ophthalmology and paediatric ophthalmology; pilot survey on childhood blindness in Delhi; training in district programme management study, on situational analysis of eye care infrastructure and human resources in India; high quality workshops in eye care for faculty of medical colleges; and development of a plan of action for "Vision 2020: The Right to Sight" initiative.

Vision 2020: The Right to Sight

It is a global initiative to reduce avoidable (preventable and curable) blindness by the year 2020. India is also committed to this initiative. The plan of action for the country has been developed with following main features:

1. Target diseases are cataract, refractive errors, childhood blindness, corneal blindness, glaucoma, diabetic retinopathy.
2. Human resource development as well as infrastructure and technology development at various levels of health system. The proposed four-tier structure includes Centre of Excellence (20); Training Centres (200), Service Centres (2000), and Vision Centres (20,000).

Fig. 8 shows the proposed structure for primary, secondary and tertiary eye care.

---

Universal eye health: a global action plan 2014–2019 (26A)

WHO estimates that in 2010 there were 285 million people usually impaired, of which 39 million were blind. If just the two major causes of visual impairment were considered priorities and control measures were implemented consistently by providing refractive services and offering cataract surgery to the visually impaired, in need, two-thirds of the visually impaired people could recover good eye sight.

Protection of effective and accessible eye care services is the key to control measures. The preference should be given to strengthening eye care services through their integration into the primary health care and health system development, as almost all causes of visual impairment are avoidable, e.g., diabetes mellitus, smoking, premature birth, rubella, vitamin A deficiency, etc., and visual impairment is frequent among older age groups. Improvements in the areas of maternal, child and reproductive health and the provision of safe drinking water and basic sanitation are important. Eye health should be included in the broader non-communicable and communicable disease frameworks, as well as those addressing ageing populations. There are three indicators to measure progress at the national level. They are:

1. The prevalence and causes of visual impairment. As a global target, reduction in prevalence of avoidable visual impairment by 25 per cent by 2019 from the baseline of 2010 has been selected for this action plan,
2. The number of eye care personnel; and
3. Cataract surgical service delivery. The cataract surgical rate (number of surgeries performed per year, per million population) and cataract surgical coverage (number of individuals with bilateral cataract causing visual impairment, who have received cataract surgery on one or both eyes).
IODINE DEFICIENCY DISORDERS (IDD) PROGRAMME

India commenced a goitre control programme in 1962, based on iodized salt. At the end of three decades, the prevalence of the disease still remained high.

As a result, a major national programme — "The IDD Control Programme" — was initiated in which nation-wide, rather than area-specific use of iodized salt is being promoted. It was decided as a national policy to fortify all edible salt in a phased manner by end of 5th Plan. The essential components of a national IDD programme are use of iodized salt in place of common salt, monitoring and surveillance, manpower training and mass communication.

The objectives of the programme are (1):
1. Surveys to assess the magnitude of the Iodine Deficiency Disorders in districts.
2. Supply of iodized salt in place of common salt.
3. Resurveys to assess iodide deficiency disorders and the impact of iodized salt after every 5 years in districts.
4. Laboratory monitoring of iodized salt and urinary iodine excretion.
5. Health education and publicity.

Significant achievements

Consequent upon liberalization of iodized salt production, Salt Commissioner has issued licenses to 824 salt manufacturers out of which 532 units have commenced production. These units have an annual production capacity of 129 lakh metric tonnes of iodized salt.

The production/supply of iodized salt from April 2013 to March 2014 was 56.64 lakh tonnes and 55.08 lakh tonnes. Notification banning the sale of non-iodized salt for different human consumption in the entire country is already issued under "Food Safety & Standards Act 2006 and Regulations 2011".

For effective implementation of National Iodine Deficiency Disorders Control Programme 33 States/UTs have established Iodine Deficiency Disorders Control Cells in their State Health Directorates.

UNIVERSAL IMMUNIZATION PROGRAMME

Experience with smallpox eradication programme showed the world that immunization was the most powerful and cost-effective weapon against vaccine-preventable diseases. In 1974, the WHO launched its "Expanded Programme on Immunization" (EPI) against six, most common, preventable childhood diseases viz. diptheria, pertussis (whooping cough), tetanus, polio, tuberculosis and measles. From the beginning of the programme UNICEF has been providing significant support to EPI.

"Expanded" in the WHO definition meant adding more disease controlling antigens of vaccination schedules, extending coverage to all corners of a country and spreading services to reach the less privileged sectors of the society (27). The primary health care concept as enunciated in the 1978 Alma-Ata Declaration included immunization as one of the strategies for reaching the goal of "Health For All" by the year 2000. While the WHO's programme is called EPI, the UNICEF in 1985 renamed it as "Universal Child Immunization" (UCI). There was absolutely no difference between these two. The goal was the same, i.e., to achieve universal immunization by 1990. EPI is regarded as the instrument of UCI (28).

The Government of India launched its EPI in 1978 with the objective of reducing the mortality and morbidity resulting from vaccine-preventable diseases. Although aimed to achieve self-sufficiency in the production of vaccines, Universal Immunization Programme was started in India in 1985. It has two vital components: immunization of pregnant women against tetanus, and immunization of children in their first year of life against the six EPI target diseases. The aim was to achieve 100 per cent coverage of pregnant women with 2 doses of tetanus toxoid (or a booster dose), and at least 85 per cent coverage of infants with 3 doses each of DPT, OPV, one dose of BCG and one dose of measles vaccine by 1990. Universal immunization was first launched in 30 selected districts and catchment areas of 50 Medical Colleges in November 1985. The programme has now been extended to all the districts and practice areas of all the 242 Medical colleges, thus creating a base for wider coverage (29). A "Technology Mission on Vaccination and Immunization of Vulnerable Population, specially Children" was set up to cover all aspects of the immunization activity from research and development to actual delivery of services to the target population (30).

The immunization services are being provided through the existing health care delivery system (i.e., MCH centres, primary health centres and subcentres, hospitals, dispensaries and EPI units). There is no separate cadre of staff for EPI. The recommended immunization schedule is on page 123.

Although the target was "universal" immunization by 1990, in practice, no country, even in the industrialized world, has ever achieved 100 per cent immunization in children. "Universal" immunization is, therefore, best interpreted as implying that no child should be denied immunization against tuberculosis, diptheria, whooping cough, tetanus, polio and measles. It is, however, generally agreed that when immunization coverage reaches a figure of 80 per cent or more, then disease transmission pattern are so severely disrupted as to provide a degree of protection even for the remaining children who have not been immunized, because of "herd immunity" (31). It is also important that children are immunized during the first year of life and that levels of immunization are sustained so that each new generation is protected.

Significant achievements have been made in India. At the beginning of the programme in 1985–86, vaccine coverage varied between 29 per cent for BCG and 41 per cent for DPT. By the end of 2012, coverage levels had gone up significantly to about 87 per cent for tetanus toxoid for pregnancy (from about 67 per cent for BCG, 72 per cent for DPT 3 doses, 74 per cent for measles, 70 per cent for OPV 3 doses and 70 per cent for HepB). Since then, there is a significant decline in the reported incidence of the vaccine preventable diseases as compared to their incidence in 1987, as shown in Table 9.

To strengthen routine immunization, Government of India has planned the State Programme Implementation Plan (PIP) part C. It consists of: (a) Support received from PHC to sub-centre and outreach sessions; (b) Deploying retired manpower to carry out immunization activities, when the usual immunization services are deficient; (c) Mobility support to district immunization officer as per state plan for monitoring and supportive supervision; (d) Review meeting at the state level with the districts at 6 monthly intervals; (e) Training of ANM, cold chain handlers, mid-level managers, refrigeration mechanics etc.; (f) Support for motoring of children to immunization session sites by ASHA, women self-help groups etc.; (g) Printing of immunization cards, monitoring sheet, cold chain chart vaccine inventory charts etc.

In addition, central government is supporting in supplies of auto-disposable syringes, downsizing the BCG vial from 20 doses to 10 doses to ensure that BCG vaccine is available in all immunization session sites, strengthening and maintenance of the cold chain system in the states, and supply of vaccines and vaccine van.

**PULSE POLIO IMMUNIZATION PROGRAMME**

Pulse Polio Immunization Programme was launched in the country in the year 1995. Under this programme children under five years of age are given additional oral polio drops in December and January every year on fixed days. From 1999–2000, house to house vaccination of missed children was also introduced. The NIDS rounds covered approximately 172 million children and SNIDS rounds cover 40–60 million children. In addition, large scale multi-district mop-ups have been conducted [4]. As a result only one case of polio was reported in 2011 i.e. the month of January. As on 25th Feb 2012, India was removed from the list of polio endemic countries, and on 27th March 2014, India was certified as polio-free country. Please see page 209 for more details.

**INTRODUCTION OF HEPATITIS-B VACCINE**

In 2018–2011, Government of India universalized hepatitis B vaccination to all States/UTs in the country. Monovalent hepatitis B vaccine is given as intramuscular injection to the infant at 6th, 10th and 14th week alongwith primary series of DPT and polo vaccines. In addition one dose of hepatitis B is given at birth for institutional deliveries within 24 hours of birth.

**INTRODUCTION OF JAPANESE ENCEPHALITIS VACCINE**

The programme was introduced in 2006 to cover 104 endemic districts in phased manner, using SA 14-14-2 vaccine. Imported from China. Single dose of JE vaccine was given to all children between 1 to 15 years of age through campaigns [3]. The JE vaccine is being integrated into routine immunization in the districts where campaign had already been conducted to immunize the new cohort of children by vaccinating with two doses at 9–12 months and 16–24 months [1].

**INTRODUCTION OF MEASLES VACCINE SECOND DOSE (OPVD)**

In order to accelerate the reduction of measles related morbidity and mortality, second opportunity for measles vaccination is being implemented. The National Advisory Group on immunization recommended introduction of 2nd dose of measles vaccine to children between 9 months and 10 years of age through supplementary immunization activity (SIA) for states where evaluated coverage of first dose of measles vaccination is less than 80 per cent. In states, with coverage of measles vaccination more than 80 per cent, the second dose of measles vaccine is given through routine immunization at 16–24 months [1].

**INTRODUCTION OF PENTAVALENT VACCINE (DPT + Hep-B + Hib)**

India introduced pentavalent vaccine containing DPT, hepatitis-B and Hib vaccines in 2002 with catch-up vaccination and other donor supports to Rajasthan and Tamil Nadu under routine immunization programme from December 2011. DPT and hepatitis B vaccination require 6 injections to deliver primary doses. With the introduction of pentavalent vaccine, a new antigen, i.e., Hib has been added which protects against haemophilus influenzae type B (associated with pneumonia and meningitis) and the number of injections are reduced to 3. The vaccine has been expanded to 6 more states, i.e., Haryana, Jammu and Kashmir, Gujarat, Karnataka, Goa and Puducherry in 2012–13. Further expansion is planned to 11 states in October 2014 and rest of 16 states from April 2015 [1].

**MISSION INDRADHANUSH**

The Government of India launched Mission Indradhanush on 25th December 2014, to cover children who are either unvaccinated or partially vaccinated against seven vaccine preventable diseases, i.e., diphtheria, whooping cough, tetanus, polo, tuberculois, measles and hepatitis B. The goal is to vaccinate all under-fives by the year 2020. Under the programme, four special vaccination campaigns will be conducted between January and June 2015. Intensive planning and monitoring experience of pulse polo immunization programme will be used. 201 high focus districts will be covered in the first phase. Of these 82 districts were from Uttar Pradesh, Bihar, Madhya Pradesh and Rajasthan. These 201 districts have nearly 50 per cent of all unvaccinated children of the country. The drive will be through a "catch-up" campaign mode. The mission will be technically supported by WHO/UNICEF/ Rotary and other donor partners. Very frequently queries come up about the vaccines and the vaccination schedule. It is important to have the exact answer to these questions.

**Questions about all vaccines (32)**

Q. If the mother/caregiver permits administration of only one injection during an infant's first visit at 9 months of age, which vaccine should be given?
   A. At 9 months of age, the priority is to give measles vaccine with OPV and Vitamin A.

Q. Which vaccines can be given to a child between 1–5 years of age, who has never been vaccinated?
   A. The child should be given DPT1, OPV1, measles and 2 ml of vitamin A solution. It should then be given the second and third doses of DPT and OPV at one month intervals. Measles second dose is also to be given as per the schedule. The booster dose of OPV/DPT can be given at a minimum of 6 months after administering OPV/DP/DPT3.

Q. Which vaccines can be given to a child between 5–7 years of age, who has never been vaccinated?
   A. The child should be given first, second and third doses of DPT can be given at a minimum of 6 months after administering DPT3 upto 7 years of age.

Q. Should one re-start with the first dose of e vaccine if a child is brought late for a dose?
   A. Do not start the schedule all over again even if the child is brought late for a dose. Pick up where the schedule
UNIVERSAL IMUNIZATION PROGRAMME

was left off. For example: If a child who has received BCG, HepB-1, DPT-1 and OPV-1 at 5 months of age, returns at 11 months of age, vacinate the child with DPT-2, HepB-2, OPV-2 and measles and do not start from DPT-1, HepB-1 again.

Q. Why is it not advisable to clean the injection site with a spirit swab before vaccination?
A. This is because some of the live components of the vaccine are killed if they come in contact with spirit.

DPT vaccine
Q. If a child could not receive DPT1, 2, 3 and OPV 1, 2, 3 according to the schedule, up to what age can the vaccine be given?
A. The DPT vaccine can be given up to 7 years of age and OPV can be given up to 5 years of age. If a child has received previous doses but not completed the schedule, do not restart the schedule and instead administer the remaining doses needed to complete the series.
Q. Why should there be a minimum gap of 4 weeks between two doses of DPT?
A. This is because decreasing the interval between two doses may not obtain optimal antibody production for protection.
Q. Why give the DPT vaccine in the antero-lateral mid thigh and not the gluteal region?
A. DPT is given in the antero-lateral mid-thigh and not the gluteal region to prevent damage to the sciatic nerve. Moreover, the vaccine deposited in the fat of gluteal region does not invoke the appropriate immune response.
Q. What should one do if the child is found allergic to DPT or develops encephalopathy after DPT?
A. If a child who is allergic to DPT or develops encephalopathy after DPT should be given the HepB/PDT vaccine instead of DPT for the remaining doses, as it is usually the P (whole cell Pertussis) component of the vaccine which causes the allergic/encephalopathy. It may be purchased with locally available resources.
Q. Why is DT replaced by DPT vaccine for children above 2 years of age?
A. As pertussis cases were reported in higher age group children and the risk of AEFs were not found to be more after DPT vaccine as compared to DT vaccine.

Measles vaccine
Q. Why give the measles vaccine only on the right upper arm?
A. The measles vaccine is given on the right upper arm to maintain uniformity and to help surveyors in verifying the receipt of the vaccine.
Q. If a child has received the measles vaccine before 9 months of age, is it necessary to repeat the vaccine later?
A. Yes, the measles vaccine needs to be administered, according to the National Immunization Schedule i.e. after the completion of 9 months until 12 months of age and at 16–24 months, if not administered in the ideal age for travel to susceptible areas.
Q. What is measles catch-up campaign?
A. A measles catch-up campaign is a special campaign to vaccinate all children in a wide age group to a state or a district with one dose of measles vaccine. The catch-up campaign dose is given to all children, both unimmunized and un-immunized, who belong to the target age group of 9 months to 10 years. The goal of a catch-up campaign is to quickly make the population immune from measles and reduce deaths from measles. A catch-up campaign must immunize nearly 100% of target age group children.
Q. Why 2nd dose of measles vaccine is introduced in the National Immunization Programme?
A. Measles is highly infectious disease causing illness and death due to complications such as diarrhea, pneumonia or brain Infection. One dose of measles vaccine at 9 months of age protects 85% of infants. With 2nd dose the aim is to protect all the children who remain unprotected after first-dose.
Q. If a child comes late for the first dose, can it get the second dose?
A. All efforts should be made to immunize the children at the right age i.e., first dose at completed 9 months to 12 months and second dose at 16–24 months. However if a child comes late then give two doses of measles vaccine at one month interval until 5 years of age.
Q. If a child received one dose of measles vaccine during an SIA campaign, should it receive the routine dose of measles vaccine?
A. Yes, the child should receive routine doses of measles vaccine according to the Immunization Schedule irrespective of the measles SIA dose.

BCG vaccine
Q. Why give BCG vaccine only on the left upper arm?
A. BCG is given on the left upper arm to maintain uniformity and for helping surveyors in verifying the receipt of the vaccine.
Q. Why do we give 0.05 ml dose of BCG to newborns (below 1 month of age)?
A. This is because the skin of newborns is thin and an intra-dermal injection of 0.1 ml may break the skin or penetrate into the deeper tissue and cause local abscesses and enlarged axillary lymph nodes. Dose of 0.05 ml is sufficient to elicit adequate protection.
Q. Why is BCG given only up to one year of age?
A. Most children acquire natural clinical/sub-clinical tuberculosis infection by the age of one year. This too protects against severe forms of childhood tuberculosis e.g. TB meningitis and miliary disease.
Q. If no scar appears after administering BCG, should one re-vaccinate the child?
A. There is no need to re-vaccinate the child, even if there is no scar.

OPV
Q. Till what age can a child be given OPV?
A. OPV can be given to children till 5 years of age.
Q. Can OPV and vitamin A be given together with DPT-booster dose?
A. Yes.
Q. Can an infant be breast-fed immediately after OPV?
A. Yes.

TT vaccine
Q. If a girl has received all doses of DPT and TT as per the NIS till 16 years of age and she gets pregnant at 20 years, should she get one dose of TT during pregnancy?
A. Give one dose of TT during the pregnancy as per the schedule.
Q. Is TT at 10 years and 16 years meant only for girls?
A. No, it is to be given to both boys and girls.
Q. Can TT be given in the first trimester of pregnancy?
A. Yes, it should be given as soon as pregnancy is diagnosed.

Hepatitis A vaccine
Q. Up to what age can hepatitis A vaccine be given?
A. According to the National Immunization Schedule, Hepatitis B vaccine should be given with the first, second and third doses of DPT1 till one year of age.

Q. Why give the birth dose of hepatitis B vaccine only within 24 hours of birth?

A. The birth dose of Hepatitis B vaccine is effective in preventing perinatal transmission of Hepatitis B if given within the first 24 hours.

**JE vaccine**

Q. If a child 16-24 months of age has been immunized with JE vaccine during an SIA, can it receive the JE vaccine again, as part of routine immunization?

A. No, currently this is a single dose vaccine and should not be repeated.

Q. If a child above 2 years (24 months) of age has not received the JE vaccine through either RI or an SIA, should he/she be given the JE vaccine?

A. Yes, the child is eligible to receive a dose of the JE vaccine, through RI, till the age of 15 years.

Following are some Do's and Don'ts during immunization sessions (32)

<table>
<thead>
<tr>
<th>Do's</th>
<th>Don'ts</th>
</tr>
</thead>
</table>
| Vaccination schedule  
- It is safe and effective to give BCG, DPT, OPV and measles vaccines at the same time to a child who has completed 9 months and never been vaccinated.  
- Give BCG to infants less than 1 year of age.  
- Give BCG to children above 1 year of age.  
- If a child is brought late for a dose, pick up where the schedule was left off.  
- For example, if a child left with DPT2 and comes after 3 months give DPT3.  
| Withhold the vaccine in case of illness such as cold, cough, diarrhoea or fever.  |
| Cold chain  
- Check expiry date and VVM label of vaccine vial before immunizing every child.  
- Keep the vaccines and diluents in a sterile bag/zipper bag in the centre of vaccine carrier with 4 conditioned ice-packs. Make sure that the diluents are also at ≤ 2 to + 8 centigrade before reconstitution.  
- Take one ice pack from vaccine carrier and keep reconstituted BCG & Measles vaccines only on the top of the ice pack.  
| Leave vaccine carrier in sunlight; this spoils vaccines that are sensitive to heat and light.  |
| Vaccine handling and administration  
- Welcome beneficiaries.  
- Wash hands before conducting the session.  
- Verify beneficiary's record and age of the child.  
- Screen for contraindications.  
- Check label of the vial and expiry date.  
- Lightly shake the vial of T.Series Vaccine before drawing the dose.  
- Use a new 10-seringe for each injection and new disposable syringe for each reconstitution.  
- Use correct diluent for reconstitution of vaccine.  
- Give appropriate vaccine.  
- Inject vaccine using the correct site and route for the vaccine e.g. Intradermal in left arm for BCG, subcutaneous in right arm for Measles; intramuscular in anterolateral aspect of mid thigh for DPT and Hepatitis B.  
- Allow dose to self-disperse instead of massaging.  
- Explain potential adverse events following immunization and what to do.  
- Discuss with beneficiaries/parents about next visit.  
| Use un-sterile syringe or needle for immunization.  |
| Recording and reporting  
- Fully document each immunization in the immunization card, tally sheet and immunization register. Ask parents/guardians to bring the card on next visit.  
- Retain the card.  
| Turn away beneficiaries for not bringing the card.  |
| Adverse events following immunization (AEFI)  
- In case of serious AEFI refer the patient to appropriate health facility, inform your supervisor immediately – document the type of vaccine(4), batch number, expiry date, and full address of the child.  
- Report all serious AEFI's to the MOH.  
| Report minor reaction following vaccination. (mild fever of less than three days, redness and pain).  |
| Social mobilization  
- Use vaccination card to remind parents when to return with their child.  
- Extend community term like AWI, ARHA, IGOs and other community-based workers to remind parents of the importance of full immunization.  
| Leave any community meeting without communicating about immunization session days.  |

Source: (32)
The Ministry of Health and Family Welfare is implementing various schemes and programmes and national initiatives to provide universal access to quality health care. The approach is to increase access to the decentralized health system by establishing new infrastructure in deficit areas and by upgrading the infrastructure in existing institutions. As part of the plan process, many different programmes have been brought together under the overarching umbrella of National Health Mission (NHM), with National Rural Health Mission (NRHM) and National Urban Health Missions (NUHM) as its two sub-Missions. The National Health Mission was approved in May 2013. The main programmatic components include health system strengthening in rural and urban areas; Reproductive - Maternal - Newborn - Child and Adolescent Health (RMNCH+A); and control of communicable and non-communicable diseases. An important achievement of NHM has been considerable reduction in out of pocket expenses from 72 per cent to 60 per cent (1).

The Government of India has introduced a series of programmes over the past two decades to address maternal and newborn health. The major milestones so far include (3):

a. 1992 - Child Survival and Safe Motherhood Programme (CSSM):

b. 1997 - RCH I

c. 1997 - RCH II

d. 2005 - National Rural Health Mission
e. 2013 - RMNCH + A Strategy
f. 2013 - National Health Mission

g. 2014 - India Newborn Action Plan (INAP)

The RMNCH + A strategy is based on a continuum of care approach and defines integrated packages of services for different stages of life. This approach brings focus on adolescents as a critical life stage and linkages between child survival, maternal health and family planning efforts. It aims to strengthen the referral linkages between community and facility based health services and ensure the various levels of the health system itself. These packages provide a framework for delivering services at the state and district level. For details please refer to page 461.

Recently, new initiatives have been launched under NHM. Rashtriya Bal Swasthya Karyakram (RBSK) was launched to provide comprehensive care and improve the quality of life of children through early detection of birth defects, diseases, deficiencies, and development delays including malnutrition. Another initiative, Rashtriya Kishor Swasthya Karyakram (RKSK) was launched to comprehensively address the health needs of the 253 million adolescents, who account for over 21% of the country’s population, by bringing in several new dimensions like mental health, nutrition, substance misuse, injuries and violence, and non-communicable diseases.

In addition to these initiatives, the Weekly Iron Folic Acid Supplementation Programme (WIFSP) was launched to address adolescent anaemia. In this programme supervised iron-folic acid (IFA) tablets are given to adolescent population between 10–19 years of age in both rural and urban areas throughout the country. NHM is a step towards realising the objective of universal health coverage in the country (1).

NUHM seeks to improve the health status of the urban population particularly slum dwellers and other vulnerable section by facilitating their access to quality health care. NUHM would cover all state capitals, district headquarters and about 779 other cities/towns with a population of 50,000 and above (as per census 2011) in a phased manner. Cities and towns below 50,000 population will be covered by NRHM. The NUHM will focus on (27):

1. Urban poor population living in listed and unlisted slums;
2. All other vulnerable population such as homeless, rag-pickers, street children, rickshaw pullers, construction and brick and lime-kiln workers, sex workers and other temporary migrants;
3. Public health threat on sanitation, clean drinking water, vector-borne diseases;
4. Strengthening public health capacity of urban local bodies.

The treatment of seven metropolitan cities, viz., Mumbai, New Delhi, Chennai, Kolkata, Hyderabad, Bengaluru and Ahmedabad will be different. These cities are expected to manage NUHM through their Municipal Corporation directly.

The NUHM will provide flexibility to the states to choose which model suits the needs and capacities of the states to best address the healthcare needs of the urban poor. Models will be decided through community led action. All the services delivered under the urban health delivery system through the urban PHCs and urban CWCs will be universal in nature, whereas the outreach services will be targeted to the target group (slum dwellers and other vulnerable groups). Outreach services will be provided through the Female Health Workers (FHWs), essentially ANMs with an induction training of three to six months, who will be placed at the Urban PHCs. These ANMs will report at the UPHC and then move to their respective areas for outreach services on designated days. On other days, they will conduct immunization and ANC clinics etc. at the UPHC itself.

The NUHM would encourage the effective participation of the community in planning and management of health care services. It would promote a community health volunteer – Accredited Social Health Activist (ASHA) or Link Worker (LW) in urban poor settlement (one ASHA for 1000–1500 urban poor population covering about 200 to 500 households); ensure the participation by creation of community based institutions like Mahila Arogya Samiti (MAS) (50–100 households) and Rogi Kalyan Samiti. However, the states will have the flexibility to either engage ASHA or entrust her responsibilities to MAS. In that case, the incentives accruing to ASHA would accrue to MAS (34). The NUHM would provide annual grant of Rs. 5000/- to MAS every year.

Essential services to be rendered by the ASHA may be as follows (34):

(i) Active promoter of good health practices and enjoying community support.

(ii) Facilitate awareness on essential RCH services, sexuality, gender equality, age at marriage/pregnancy; motivation on contraception adoption, medical termination of pregnancy, sterilisation, spacing methods. Early registration of pregnancies, pregnancy care, clean and safe delivery, nutritional care during...
pregnancy, identification of danger signs during pregnancy; counselling on immunisation, ANC, PNC etc., act as a depot holder for essential provisions like oral re-hydration therapy (ORS), Iron Folie Acid Tablet (IFA), chloroquine, oral pills and condoms, etc.; identification of target beneficiaries and support the ANM in conducting regular monthly outreach sessions and tracking service coverage.

(iii) Facilitate access to health related services available at the Anganwadi/Primary Urban Health Centres/Urban Local Body (ULBs) and other services being provided by the ULB, State and Central Government.

(iv) Formation and promotion of Mahila Aroga Samitis in her community.

(v) Arrange escort/accompany pregnant women and children requiring treatment to the nearest Urban Primary Health Centre, secondary/tertiary level health care facility.

(vi) Reinforcement of community action for immunization, prevention of water borne and other communicable diseases like TB (DOTS), Malaria, Chikungunya and Japanese Encephalitis.

(vii) Carrying out preventive and promotional health activities with ANM/Mahila Aroga Samiti.

(viii) Maintenance of necessary information and records about births and deaths, immunization, antenatal services in her assigned locality as also about any unusual health problem or disease outbreak is the slum, and share it with the ANM in charge of the area.

In return for the services rendered, she would receive a performance based incentive. For this purpose a revolving fund would be kept with the ANM in the PHC (in the PHC account), which would be replenished from time to time.

The urban health care facilities are as shown in Fig. 9.

Urban Primary Health Centre

Functional for a population of around approximately 50,000-60,000, the U-PHC may be located preferably within a slum or near a slum within half a kilometer radius, catering to a slum population of approximately 25,000-30,000, with provision for OPD. The cities, based upon the local situation may establish a U-PHC for 75,000 for areas with very high density and also establish one for around 5,000-10,000, slum population for isolated slum clusters.

At the U-PHC level services provided will include OPD (consultation), basic laboratory diagnosis, drug/contraceptive dispensing, apart from distribution of health education material and counselling for all communicable and non-communicable diseases. In order to ensure access to the urban slum population at convenient timings, the U-PHC may provide services from 2 pm to 8 pm. It will not include in-patient care. The staff pattern will be as shown in Fig. 9.

Referral unit

Urban Community Health Centre (U-CHC) may be set up as a satellite hospital for every 4-5 U-PHCs. The U-CHC would cater to a population of 2,50,000. It would provide in-patient services and would be a 30-50 bedded facility. U-CHCs would be set up in cities with a population of above 5 lakhs, wherever required. These facilities would be in addition to the existing facilities (SDH/DH) to cater to the urban population in the locality.

For every 2.5 lakh population (5 lakhs for metropolis) U-CHC

In-patient facility, 30-50 bedded (100 bedded in metros) Only for cities with a population of above 5 lakhs

For every 50,000 population

U-PHC:
- MO IC - 1
- 2nd MO (par time) - 1
- Nurse - 1
- LHV - 1
- APM - 1
- Public Health Manager, Mobilisation Officer - 1
- Security Staff - 1

M & E Unit - 1

For every 10,000 population

1 ANM

Outreach sessions in area of every ANM on weekly basis

FIG. 9

Urban Health Care Facilities

Source: (35)

For the metro cities, the U-CHCs may be established for every 5 lakh population with 100 beds.

For setting up the U-CHCs the Central Government would provide only a one time capital cost, and the recurrent costs including the salary of the staff would be borne by the respective state governments.

The U-CHC would provide medical care, minor surgical facilities and facilities for institutional delivery.

Referral linkages

Existing hospitals, including ULB maternity homes, state government hospitals and medical colleges, apart from private hospitals will be empanelled/accredited to act as referral points for different types of healthcare services like maternal health, child health, diabetes, trauma care, orthopaedic complications, dental surgery, mental health, critical illnesses, cancer management, tuberculosis counselling/cessation, critical illness, surgical cases etc.

The services provided at different levels are as shown in Table 10 (35).

* Year 2013-14 bring the baseline year, the indicators for these NUHM components would be zero. For other indicators, the figure for 2012-13 will be the base line.

Source : (34)

Impact level targets of NUHM are as follows:

1. Reduce IMR by 40% (in urban areas) - National Urban IMR down to 20 per 1,000 live births by 2017
2. Reduce MMR by 50%
3. Achieve universal access to reproductive health including 100% institutional delivery
4. Achieve replacement level fertility (TFR 2.1)
5. Achieve all targets of disease control programmes

Source : (75)

NATIONAL RURAL HEALTH MISSION

Recognizing the importance of health in the process of economic and social development and to improve the quality of life of its citizens, the government of India launched "National Rural Health Mission" (NRHM) on 5th April, 2005 for a period of 7 years (2005-2012) and recently extended up to year 2017. The mission seeks to improve rural health care delivery system. It is operational in the whole country with special focus on 18 states viz. 8 Empowered Action Group states (Bihar, Jharkhand, Madhya Pradesh, Chhattisgarh, Uttar Pradesh, Uttarakhand, Orissa and Rajasthan), 8 North East states (Assam, Arunachal Pradesh, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura), Himachal Pradesh and Jammu and Kashmir. By making necessary changes in the basic health care delivery
system the mission adopts a synergic approach by relating health to determinants of good health viz. nutrition, sanitation, hygiene and safe-water and also brings the Indian system of medicine (AYUSH) to the mainstream of health care (5).

The main aim of NRHM is to provide accessible, affordable, accountable, effective and reliable primary health care, and bridging the gap in rural health care through creation of a cadre of Accredited Social Health Activist (ASHA). The mission is an instrument to integrate multiple vertical programmes alongwith their funds at the district level. The programmes integrated into NRHM are existing programmes of health and family welfare including RCH I; national vector borne disease control programmes against malaria, filaria, kala-azar, dengue fever/DF/HF and Japanese encephalitis; national leprosy eradication programme; revised national tuberculosis control programme; national programme for control of blindness; iodine deficiency disorder control programme, and integrated disease surveillance project (5).

PLAN OF ACTION TO STRENGTHEN INFRASTRUCTURE

1. Creation of a cadre of Accredited Social Health Activist (ASHA).

2. Strengthening sub-centres by: (a) Supply of essential drugs both allopathic and AYUSH to the sub-centre; (b) In case of additional outlay, provision of multipurpose worker (male)/additional ANMs wherever needed, sanction of new sub-centres and upgrading existing sub-centres; and (c) Strengthening sub-centres with unified funds of Rs. 10,000 per annum in all 18 states.

3. Strengthening Primary Health Centres: Mission aims at strengthening PHCs for quality preventive, promotive, curative, supervisory and outreach services through: (a) Adequate and regular supply of essential drugs and equipment to PHCs (including supply of auto-disabled syringes for immunisation); (b) Provision of 24 hours service in at least 50 per cent PHCs by including an AYUSH practitioner; (c) Following standard treatment guidelines; (d) Upgradation of all PHCs for 24 hours referral service and provision of second doctor at PHC level (one male and one female) on the basis of felt need; strengthening the ongoing communicable disease control programmes and new programmes for control of non-communicable diseases.

4. Strengthening Community Health Centres for First Referral care by: (a) Operating all existing CHCs (30–50 beds) as 24 hours first referral units, including posting of an anaesthetist; (b) Codification of new ‘Indian Public Health Standards’ (refer to chapter 20 for more details) by setting up norms for infrastructure, staff, equipment, management etc. for CHCs; (c) Promotion of ‘Rogi Kalyan Samiti’ for hospital management; (d) Developing standards of services and costs in hospital care.

The NRHM infrastructure is as shown in Fig. 10.

District is the core unit of planning, budgeting and implementation of the programme. All vertical health and family welfare programmes at district level have merged into one common ‘District Health Mission’ and at state level into ‘State Health Mission’. There is provision of a ‘mobile medical unit’ at district level for improved outreach services.

Since almost 75 per cent of health services are being currently provided by the private sector, it is contemplated that involving the private sector as part of the RCH I initiatives will provide more effective health care delivery system. Thus setting up of ‘Public Private Partnership’ (PPP) is to help to make the RCH I programme better, and ensure availability of preventive and curative reproductive and child health services in the community.

Major initiatives under NRHM

1. Selection of ASHA: ASHA must be the resident of the village – a woman (married / widow / divorced) preferably in the age group of 25 to 45 years with formal education up to eighth class, having communication skills and leadership qualities. Adequate representation from the disadvantaged populations group will ensure to serve such groups better.

The general norm of selection is one ASHA for 1000 population. In tribal, hilly and desert areas the norm could be relaxed to one ASHA per habitation.

Role and responsibilities of ASHA

ASHA will be a health activist in the community who will create awareness on health. Her responsibilities will be as follows (36):

1. ASHA will take steps to create awareness and provide information to the community on determinants of health such as nutrition, basic sanitation and hygiene practices, healthy living and working conditions, information on existing health services, and the need for timely utilization of health and family welfare services.

2. She will counsel women on birth preparedness, importance of safe delivery, breast-feeding and complementary feeding, immunization, contraception

Fig 10

The NRHM Infrastructure
and prevention of common infections including reproductive tract infection/sexually transmitted infection and care of the young children.

3. ASHA will mobilize the community and facilitate them in accessing health and health related services available in the anganwadi and primary health centres, such as immunization, antenatal check-up, postnatal check-up, supplementary nutrition, sanitation and other services being provided by the government.

4. She will work with the village health and sanitation committee of the gram panchayat to develop a comprehensive village health plan.

5. She will arrange escort/accompany pregnant women and children requiring treatment and admission to the nearest pre-identified health facility i.e. primary health centre/community health centre/first Referral Unit.

6. ASHA will provide primary medical care for minor ailments such as diarrhoea, fevers, and first-aid for minor injuries. She will be a provider of directly observed treatment short-course (DOTS) under revised national tuberculosis control programme.

7. She will also act as a depot holder for essential provisions being made available to every habitaiton like oral re-hydration therapy, iron folic acid tablet, chloroquine, disposable delivery kits, oral pills and condoms etc. A drug kit will be provided to each ASHA. Contents of the kit will be based on the recommendations of the expert/technical advisory group set up by the government of India, and include IACYSHUS and all other essential items.

8. Her role as a provider can be enhanced subsequently. Strees can explore the possibility of graded training to her for providing newborn care and management of a range of common elements, particularly childhhood illnesses.

9. She will inform about the births and deaths in her village and any unusual health problems/disease outbreaks in the community to the sub-centre/primary health centre.

10. She will promote construction of household toilets under total sanitation campaign.

Role and integration with Anganwadi (36)

Anganwadi worker will guide ASHA in performing following activities: (a) Organizing Health Day once/twice a month. On health day, the women, adolescent girls and children from the village will be mobilized for orientation on health and nutrition, the importance of nutritious food, personal hygiene, care during pregnancy, importance of antenatal check-up and institutional delivery, home remedies for minor ailments and importance of immunization etc. AWWs will inform ANM to participate and guide organizing the Health Days at anganwadi centre; (b) AWWs and ANMs will act as resource persons for the training of ASHA; (c) IEC activity through display of posters, folk-songs etc. on these days can be undertaken to sensitize the beneficiaries on health related issues; (d) Anganwadi workers will be depot holder for drug kits and will be issuing it to ASHA. The replacement of the consumed drugs can also be done through AWW; (e) AWW will update the list of elgible couples and also the children less than one year of age in the village with the help of ASHA; and (f) ASHA will support the AWW in mobilizing pregnant and lactating women and infants for nutrition supplement. She would also take initiative for bringing the beneficiaries from the village on specific days of immunization, health check-ups/health days etc. to anganwadi centres.

Role and integration with ANM (36)

The committee guide ASHA in performing following activities: (a) She will hold weekly/fortnightly meeting with ASHA and discuss the activities undertaken during the week. She will guide her in case ASHA had encountered any problem during the performance of her activity; (b) AWWs and ANMs will act as resource person for the training of ASHA; (c) ANMs will inform ASHA regarding date and time of the outreach session and will also guide her for bringing the beneficiary to the outreach session; (d) ANM will participate and guide in organizing the Health Days at anganwadi centre; (e) She will take the help of ASHA in updating eligible couple register of the village concerned; (f) She will utilize ASHA in motivating the pregnant women for taking full course of iron and folic acid tablets and tetanus toxoid injections etc.; (g) ANMs will orient ASHA on dose schedule and side effects of oral pills; (h) ANMs will educate ASHA on danger signs of pregnancy and labour so that she can timely identify and help beneficiary in getting further treatment; and (i) ANMs will inform ASHA on date, time and place for initial and periodic training schedule. She will also ensure that during the training ASHA gets the compensation for performance and also TADA for attending the training.

2. Rogi Kalyan Samiti (Patient Welfare Committee) Hospital Management Society. It is a simple yet effective management structure. The committee is a registered society whose members act as trustees to manage the affairs of the hospital and is responsible for upkeep of the facilities and ensure provision of better facilities to the patients in the hospital. Financial assistance is provided to these committees through unit fund to undertake activities for the benefit of the patients. 31,109 Rogi Kalyan Samiti (RKS) have been set up involving the community members in almost all District Hospitals (DHs), Sub-District Hospitals (SDHs), Community Health Centres (CHCs) and Primary Health Centres (PHCs) till March 2014.

3. The union grants to sub-centres (SCs): The SCs are far better equipped now with blood pressure measuring equipment, haemoglobin (hb) measuring equipment, stethoscope, weighing machine etc. This has facilitated provision of quality antenatal care and other health care services.

4. The Village Health Sanitation and Nutrition Committee (VHSNC): It is an important tool of community empowerment and participation at the grassroots level. The VHSNC reflects the aspirations of the local community, especially the poor households and children. Upto 31st March 2014, 5,12 lakh VHSNCs have been set up across the country.

5. Janani Suraksha Yojana (JAY): aims to reduce maternal mortality among pregnant women by encouraging them to deliver in government health facilities. Under the scheme, cash assistance is provided to eligible pregnant women for giving birth in a government health facility. Since the inception of NRHM, 7.94 crore women have benefited under this scheme. For details please refer to page 405.
6. Janani Shishu Suraksha Karyakram (JSSK): Launched on 1st June, 2011, the JSSK entitles all pregnant women delivering in public health institutions to certain free and no expense delivery, including caesarean section. This marks a shift to an entitlement based approach. Please refer to the relevant figures and tables.

7. National Mobile Medical Units (NMIMU): Support has been provided in 418 out of 640 districts for 2127 MMUs under NRHM in the country. To increase visibility, awareness, and accountability, all Mobile Medical Units have been repositioned as ‘National Mobile Medical Unit Service’ with universal colour and design.

8. National Ambulance Services: NRHM has supported free ambulance services to provide patients transport in every nook and corner of the country connected with a toll free number. Over 16,000 basic and emergency patient transport vehicles have been provided under NRHM. Besides these, over 4,769 vehicles have been revamped to transport pregnant women and sick infants from home to public health facilities and back. 38 states have set up 6,738 call centres for effective patient transport systems.

9. Web-enabled Mother and Child Tracking System (MCTS): The name-based tracking of pregnant women and children has been initiated under NRHM with an intention to track every pregnant woman, infant and child up to the age of twelve years by name, for ensuring delivery of services like timely ante-natal care, institutional delivery and postnatal care for the mother, and immunization and other related services for the child. The MCTS is to be fully updated for regular and effective monitoring of service delivery, including tracking and monitoring of severely anaemic women, low birth weight babies and sick neonates. In the long run it could be used for tracking the health status of the girl child and school health services. A more recent initiative is to link MCTS with AADHAR in order to track subsidiaries to eligible women (57).

New initiatives (6)

- Home delivery of contraceptives (condoms, oral contraceptive pills, emergency contraceptive pills) by ASHA.
- Conducting District Level Household Survey (DLHS) - 4 in 26 States/UTs where the Annual Health Survey (AHS) is not being done.
- Modifications in the scheme for promotion of menstrual hygiene covering 152 districts and nearly 1.5 crores of adolescent girls in 20 states.
- Differential financial approach for comprehensive health care by which allocation of Unified Funds and Rogi Kalan Samiti grants will be made based on the case load and services provided by the health facility.
- Involving ASHA in Home Based Newborn Care.
- Revision in the criteria of allocation of funds to the states under JRBHM based on the performance of the states against the monitorable targets and implementation of specific reform agenda in the health sector.
- Expansion of Village Health and Sanitation Committees to include nutrition in its mandate and renaming it as Village Health, Sanitation and Nutrition Committee (VHNSC);
- Partial modification of the centrally sponsored scheme for development of AVUSH hospitals and dispensaries for maintaining AVUSH under NRHM in the country.
- Rashtrirah I Swastiya Karyakram (RISBK): This initiative was launched in February 2013 and provides for Health Screening and Early Intervention Services through early detection and management of 4 Di I.e., Defects at birth, Diseases, Deficiencies, and Disability. For details please refer to page 460.
- Rashtriya Kishor Swastiya Karyakram (RKSK): This is a new initiative, launched in January 2016 to reach out to 253 million adolescents in the country in their own spaces and introduces peer-led interventions at the community level, supported by augmenting the facility based services. This initiative broadens the focus of the adolescent health programme beyond reproductive and sexual health to health in focus on life skills, suicide, injuries and violence (including gender based violence), non-communicable diseases, mental health and substance misuse (71).
- Mother and Child Health Wings (MCHWings): 100/50/30 bedded Maternal and Child Health (MCH) Wings have been sanctioned in public health facilities with high bed occupancy to cater to the increased demand for services. More than 28,000 additional beds have been sanctioned across 470 health facilities across 18 states.
- Free drugs and free diagnostic service.
- National Iron+ Initiative is another new initiative launched in 2013, to prevent and control iron deficiency anaemia among pregnant women under NRHM in India. Besides pregnant women and lactating mothers, it aims to provide IFA supplementation for children, adolescents and women in reproductive age group. Iron and Folic Acid Supplementation (WIFS) for adolescents is an important strategy under this initiative. WIFS (for 10-19 years age) has already been rolled out in 32 states and UTs under the National Iron Plus Initiative. WIFS covered around 3 crore beneficiaries in December 2013 (1).
- Reproductive, Maternal, Newborn, Child and Adolescent Health Services (RMNCH+A): A continuum of care approach has now been adopted under NRHM with the articulation of strategic approach to Reproductive Maternal, Newborn, Child and Adolescent Health (RMNCH+A) in India. This approach brings focus on adolescents as a critical life stage and linkages between child survival, maternal health and family planning efforts. It aims to strengthen the referral linkages between community and facility based health services and between the various levels of health system itself. Please refer to page 461 for details.
- Delivery Points (DPs): Health facilities that have a high demand for services and performance above a certain benchmark have been identified as “Delivery Points” with the objective of providing comprehensive reproductive, maternal, newborn, child and adolescent health services (RMNCH+A) at these facilities. Funds have been allocated to strengthen these DPs in terms of infrastructure, human resource, drugs, equipment etc. Around 17,000 health facilities have been identified as “Delivery Points” for focussed support under NRHM.
- Universal Health Coverage (UHC): Moving towards Universal Health Coverage (UHC) is a key goal of the 12th Five Year Plan. The National Health Mission is the primary vehicle to move towards this goal.
Achievements: The achievements of NRHM as on 30th June 2013 are as follows (1):

(1) 8.89 lakh ASHAs have been selected in the entire country of which 8.06 lakh ASHAs have been trained and provided with drug kits.
(2) 1,47 lakh sub-centres in the country are provided with untied funds of Rs 10,000 each. 40,426 sub-centres are functional with second ANM.
(3) 31,109 Rogi Kalyan Samitis have been registered at different level of facilities.
(4) 8,129 doctors and specialists, 70,608 ANMs, 34,665 staff nurses, 13,725 paramedics have been appointed on contract to fill critical gaps in services.
(5) 1,691 professionals (CA/MBA/MCA) have been appointed to support NRHM.
(6) 2,127 Mobile Medical Units are operational under NRHM in states.
(7) Emergency transport system operational in 12 states.
(8) Accelerated immunization programme launched in 7 North-East states and EAG (Empowered Action Group) states. Progress made in pulse polio immunization (India declared polio free country); neonatal tetanus declared eliminated in 7 states in the country; JE vaccination completed in 11 districts in 4 states.
(9) Janani Suraksha Yojana is operational in all the states. 106.57 lakh women were benefited in the year 2012-13.
(10) Integrated Management of Neonatal and Childhood Illness (IMNCI) started in 310 districts.
(11) Monthly Health and Nutrition Days being organized at village level in various states.
(12) The states have constituted 5.12 lakh Village Health Sanitation and Nutrition Committees.
(13) School health programme have been initiated in over 26 states.

Monitoring and evaluation under NRHM

A baseline survey is to be taken up at the district level incorporating facility survey (including private facilities) as well as survey of the households. The baseline survey is to help the mission in fixing decentralized measurable goals and indicators. There would be community monitoring at the village level. The panchayat raj institutions, rogi kalyan samitis, quality assurance committees at the state level and district level, state and districts health missions, mission steering group at the central level. Planning commission is to be the eventual monitor of the outcomes. External evaluation is also to be taken up at frequent intervals.

REPRODUCTIVE AND CHILD HEALTH PROGRAMME

Reproductive and child health approach has been defined as "people have the ability to reproduce and regulate their fertility, women are able to go through pregnancy and child birth safely, the outcome of pregnancies is successful in terms of maternal and infant survival and well being, and couples are able to have sexual relations, free of fear of pregnancy and of contracting disease" (38).

The concept is in keeping with the evolution of an integrated approach to the programme aimed at improving the health status of young women and young children which has been going on in the country namely family welfare programme, universal immunisation programme, oral rehydration therapy, child survival and safe motherhood programme and acute respiratory infection control etc. It is obviously sensitive that integrated RCH programme would help in reducing the cost inputs to some extent because overlapping of expenditure would not be necessary and integrated implementation would optimise outcomes at field level.

The RCH phase-I programme incorporated the components relating child survival and safe motherhood and included two additional components, one relating to sexually transmitted disease (STD) and other relating to reproductive tract infection (RTI).

The RCH programme was based on a differential approach. Inputs in all the districts were not kept uniform. While the core components was same for all districts, the weaker districts got more support and sophisticated facilities were proposed for relatively advanced districts. On the basis of crude birth rate and female literacy rate, all the districts were divided into three categories. Category A having 58 districts, category B having 184 districts and category C having 265 districts. All the districts were covered in a phased manner over a period of three years. The programme was formally launched on 15th October 1997.

RCH phase-I interventions at district level were as follows:

Interventions in all districts

- Child Survival interventions i.e. Immunization, Vitamin A (to prevent blindness), oral rehydration therapy and prevention of deaths due to pneumonia.
- Safe Motherhood interventions e.g. antenatal check up, immunization for tetanus, safe delivery, anaemia control programme.
- Implementation of Target Free Approach.
- High quality training at all levels.
- IEC activities.
- Specially designed RCH package for urban slum and tribal areas.
- District sub-projects under Local Capacity Enhancement.
- RTI/STD Clinics at District Hospitals (where not available)
- Facility for safe abortions as PHCs by providing equipment, contractual doctors etc.
- Ensured community participation through Panchayats, Women's Groups and NGOs.
- Adolescent health and reproductive hygiene.

Interventions in selected States/Districts

- Screening and treatment of RTI/STD at sub-divisional level.
- Emergency obstetric care at selected FRUs by providing drugs.
- Essential obstetric care by providing drugs and PHN/ Staff Nurse at PHCs.
- Adolescent ANM at sub-centres in the weak districts for ensuring MCH care.
- Improved delivery services and emergency care by providing equipment kits, IUD insertions and ANM kits at sub-centres.
- Facility of referral transport for pregnant women during emergency to the nearest referral centre through Panchayat in weak districts.
The major interventions under RCH – Phase I

Essential obstetric care (39)

Essential obstetric care intends to provide the basic maternity services to all pregnant women through (1) early registration of pregnancy (within 12-16 weeks), (2) provision of minimum three prenatal check ups by ANM or medical officer to monitor progress of the pregnancy and to detect any risk/complication so that appropriate care including referral could be taken in time. (3) provision of safe delivery at home or in an institution, and (4) provision of some postnatal check ups to monitor the postnatal recovery and to detect complications.

Emergency obstetric care

Complications associated with pregnancy are not always predictable, hence, emergency obstetric care is an important intervention to prevent maternal morbidity and mortality. Under the CSSM programme 1748 Referral Units were identified and supported with equipment kit E to kit P. However, these FRUs were not fully operational because of lack of manpower and adequate infrastructure. Under the RCH programme the FRUs were strengthened through supply of emergency obstetric kit, equipment kit and provision of skilled manpower on contract basis etc. Traditional Birth Attendant still plays an important role during deliveries in our society.

24-Hour delivery services at PHCs/CHCs

To promote institutional deliveries, provision has been made to give additional honorarium to the staff to encourage round the clock delivery facilities at health centers.

Medical Termination of Pregnancy

MTP is a reproductive health measure that enables a woman to opt out of an unwanted or unintended pregnancy in certain specified circumstances without endangering her life, through MTP Act 1971. The aim is to reduce maternal morbidity and mortality from unsafe abortions. The assistance from the Central Government is in the form of training of manpower, supply of MTP equipment and provision for engaging doctors trained in MTP to visit PHCs on fixed dates to perform MTP.

Control of reproductive tract infections (RTI) and sexually transmitted diseases (STD)

Under the RCH programme, the component of RTI/STD control is linked to HIV and AIDS control. It has been planned and implemented in close collaboration with National AIDS Control Organization (NACO). NACO provides assistance for setting up RTI/STD clinics upto the district level. The assistance from the Central Government is in the form of training of the manpower and drug kits including disposable equipment. Each district is assisted by two laboratory technicians on contract basis for testing blood, urine and RTI/STD tests.

Immunization

The Universal Immunization Programme (UIP) became a part of CSSM programme in 1992 and RCH programme in 1997. It will continue to provide vaccines for polio, tetanus, DPT, DT, measles and tuberculosis. The cold chain established so far will be maintained and additional items will be provided to new health facilities.

Essential newborn care

The primary goal of essential newborn care is to reduce perinatal and neonatal mortality. The main components are resuscitation of newborn with asphyxia, prevention of hypothermia, prevention of infection, exclusive breast feeding and referral of sick newborn. The strategies are to provide a medical and other facilities in essential newborn care, provide basic facilities for care of low birth weight and sick newborns in FRUs and district hospitals etc.

Diarrhoeal disease control

In the districts not implementing Integrated Management of Neonatal and Childhood Illness, the vertical programme for control of diarrhoeal disease will continue. India is the first country in the world to introduce the low osmolality Oral Rehydration Solution. Zinc is to be used as an adjunct to ORS for the management of diarrhoea. Addition of Zinc would result in reduction of the number and severity of episodes and the duration of diarrhoea. De-worming guidelines have been formulated. The incidence of diarrhoea is reduced by provision of safe drinking water.

Acute respiratory disease control

The standard case management of ARI and prevention of deaths due to pneumonia is now an integral part of RCH programme. Peripheral health workers are being trained to recognize and treat pneumonia. Cotrimoxazole is being supplied to the health workers through the drug kit.

Prevention and control of vitamin A deficiency in children

It is estimated that large number of children suffer from sub-clinical deficiency of vitamin A. Under the programme, doses of vitamin A are given to all children under 5 years of age. The first dose (1 lakh units) is given at nine months of age along with measles vaccination. The second dose (2 lakh units) is given after 9 months. Subsequent doses (2 lakh units each) are given at six months intervals upto 5 years of age (3). All cases of severe malnutrition to be given one additional dose of vitamin A.

Prevention and control of anemia in children

Iron deficiency anaemia is widely prevalent in young children. To manage anaemia, the policy has been reviewed. Infants from the age of 6 months onwards upto the age of 5 years are to receive iron supplements in liquid formulation in doses of 20 mg elemental iron and 100 mcg folic acid per day for 100 days in a year. Children 6 to 10 years of age will receive iron in the dose of 30 mg elemental iron and 250 mcg folic acid for 100 days in a year. Children above this age group would receive iron supplement in the adult dose (3).

Introduction of Hepatitis B Vaccination

Introduction of Hepatitis B in the National Immunization Programme has been approved by the Government. Under this project hepatitis B vaccine will be administered to infants alongwith the primary doses of DPT vaccine.

Training of dais

A scheme for training of dais was initiated during 2001-02. The scheme is being implemented in 156 districts in 15 states/UTs of the country. The districts have been selected on the basis of the safe delivery rates being less
than 30 per cent. The scheme was extended to all the districts of EAG states. The aim was to train at least one Dai in every village, with the objective of making deliveries safe.

**Empowered Action Group (EAG)**

An Empowered Action Group has been constituted in the Ministry of Health and Family Welfare, with Union Minister for Health and Family Welfare as chairman on 20th March 2001. At 55 per cent of the increase in the population of India is anticipated in the states of Uttar Pradesh, Bihar, Madhya Pradesh, Rajasthan, Odisha, Chhattisgarh, Jharkhand and Uttarakhand, these states are perceived to be most deficient in critical socio-demographic indices. Through EAG, these states will get focussed attention for different health and family welfare programmes.

**District Survey**

There is no regular source of data to indicate the reproductive health status of women. The RCH programme conducts district based rapid household survey to assess the reproductive health status of women. The key indicators are:

a. Percentage of pregnant women with full ANC;

b. Percentage of institutional deliveries and home deliveries;

c. Percentage of home deliveries by trained birth attendant;

d. Current contraceptive prevalence rate;

e. Percentage of children fully immunized;

f. Percentage of unmet need for family planning; and

g. Percentage of household reported visits by health worker in previous 3 months.

**RCH–PHASE II**

RCH–phase II began from 1st April 2005. The focus of the programme is to reduce maternal and child morbidity and mortality with emphasis on rural health care.

The major strategies under the second phase of RCH are:

- Essential obstetric care
  a. Institutional delivery
  b. Skilled attendance at delivery
- Emergency obstetric care
  a. Operationalising First Referral Units
  b. Operationalising PHCs and CHCs for round the clock delivery services
- Strengthening referral system

The Government of India has given some broad guidelines and strategies for achieving the reduction in maternal mortality rate and infant mortality rate. The initiatives which have been planned are:

**Essential obstetric care**

- Institutional delivery – To promote institutional delivery in RCH Phase II, it was envisaged that fifty percent of the PHCs and all the CHCs would be made operational as 24-hour delivery centres, in a phased manner, by the year 2010. These centres would be responsible for providing basic emergency obstetric care and essential newborn care and basic newborn resuscitation services round the clock. The experience of RCH phase-I indicates that giving incentive to health workers for providing round the clock services did not function well in most of the states. On the contrary there is the experience from government of Andhra Pradesh and Tamil Nadu, where round the clock delivery and newborn care services could be ensured by providing 3 to 4 staff nurses/ANM at the PHCs.
- Skilled attendance at delivery – it is now recognized globally that the countries which have been successful in bringing down maternal mortality are the ones where the provision of skilled attendance at every birth and its linkage with appropriate referral services for complicated cases have been ensured. The WHO has also emphasized that skilled attendance at every birth is essential to reduce the maternal mortality in any country. Guidelines for normal delivery and management of obstetric complications at PHC/HC for medical officers and for ANC and skilled attendance at birth for ANMs/LHWs have been formulated and disseminated to the states.
- The policy decisions: ANMs/LHWs/ SNs have now been permitted to use drugs in specific emergency situations to reduce maternal mortality. They have also been permitted to carry out certain emergency interventions when the life of the mother is at stake.

**Emergency obstetric care**

Operationalization of FRUs and skilled attendance at birth are the two activities which go hand in hand. In view of this, simultaneous steps have been taken to ensure tackling obstetric emergencies. It has been decided that all the First Referral Units be made operational for providing emergency and essential obstetric care during the second phase of RCH. The minimum services to be provided by a fully functional FRU are:

1. 24 hour delivery services including normal and assisted deliveries;
2. Emergency obstetric care including surgical interventions like vacuum suction sections;
3. Newborn care;
4. Emergency care of sick children;
5. Full range of family planning services including IUCD services;
6. Safe abortion services;
7. Treatment of STIs/RTIs;
8. Blood storage facility;
9. Essential laboratory services; and
10. Referral (transport) services.

There are three critical determinants of a facility being "declared" as a FRU. They are: availability of surgical interventions, newborn care and blood storage facility on a 24 hours basis.

To be able to perform the full range of FRU function, a health facility must have the following facilities:

(a) A minimum bed strength of 20–30. However, in difficult areas, as in the North-East states and the undererved areas of EAG states, this could initially be relaxed to 16–12 beds
(b) A fully functional operation theatre
(c) A fully functional labour room
(d) An area earmarked and equipped for newborn care in the labour room, and in the ward
(e) A functional laboratory (f) Blood storage facility
(g) 24 hour water supply and electricity supply
(h) Arrangement for waste disposal, and
(i) Ambulance facility.
Strengthening referral system

During RCH phase-I, funds were given to the Panchayat for providing assistance to poor people in the case of obstetric emergencies. Feedback from the states indicate that there was no active involvement of Panchayats in running the scheme. Based on these experiences different states have proposed different modes of referral linkage in RCH Phase II. Some of them have indicated to involve local self help groups, whereas few others have indicated to outsource it.

New initiatives

1. Training of MBBS doctors in life saving anaesthetic skills for emergency obstetric care: Provision of adequate and timely emergency obstetric care (EmOC) has been recognized as the most important intervention for saving lives of pregnant women who may develop complications during pregnancy or childbirth. The operationalisation of First Referral Unit at sub-district/CHC level for providing EmOC to pregnant women is a crucial strategy of RCH-II, which needs focused attention. The training of MBBS doctors will be undertaken for only such numbers who are required for the functioning of FRUs and CHCs, and shall be limited to the requirement of tackling emergency obstetric situations only. It is not the replacement of the specialist anaesthetist. Government of India is also introducing training of MBBS doctors in obstetric management skills. Federation of Obstetric and Gynaecology Society of India has prepared a training plan for 16 weeks in all obstetric management skills, including caesarean section operation.

2. Setting up of blood storage centres at FRUs according to guidelines of India.

JANANI SURAKSHA YOJANA

The National Maternity Benefit scheme has been modified in the new scheme called Janani Suraksha Yojana (JSY). It was launched on 12th April, 2005. The objectives of the scheme are – reducing maternal mortality and infant mortality through encouraging delivery at health institutions, and focusing at institutional care among women in below poverty line families.

The salient features of Janani Suraksha Yojana are as follows (5):

a. It is a 100 per cent centrally sponsored scheme;

b. Under National Rural Health Mission, it integrates the benefit of cash assistance with institutional care during ante-natal, delivery and immediate post-partum care. This benefit will be given to all women, both rural and urban, belonging to below poverty line household and aged 19 years or above, or up to first two live births. However, with a view to give special focus in 10 low performing states (states having low institutional delivery rate), namely Uttar Pradesh, Uttarakhand, Madhya Pradesh, Jharkhand, Bihar, Rajasthan, Chhattisgarh, Orissa, Assam and Jammu & Kashmir, the benefit will be extended up to the third child if the mother, of her own accord, chooses to undergo sterilization in the health facility where she delivered, immediately after delivery. The other states are called high performing states. The Accredited Social Health Activist (ASHA) would work as a link health worker between the poor pregnant women and public sector health institution in the low performing states. ASHA would be responsible for making available institutional antenatal as well as postnatal care. She would also be responsible for escorting the pregnant women to the health centre. The scale of assistance under the scheme from 2012-13 would be as follows:

<table>
<thead>
<tr>
<th>Rural Area</th>
<th>Urban Area</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category</td>
<td>Mother’s</td>
</tr>

</tr>
</tbody>
</table>

LPS: Low performing states, HPS: High performing states

* ASHA incentive of Rs. 600/- in rural areas includes Rs. 500/- for ANC component and Rs. 300/- for accompanying pregnant woman for institutional delivery.

** ASHA incentive of Rs. 400/- in urban areas includes Rs. 200/- for ANC component and Rs. 200/- for accompanying pregnant woman for institutional delivery.

Source: (1)

The eligibility of cash assistance is as follows (1):

1. In low performing states (LPS): All women, including those from SC and ST families, delivering in government health centres like sub-centre, primary health centre, community health centre, first referral unit, general wards of district and state hospitals or accredited private institutions.

2. In high performing states (HPS): Below poverty line women aged 19 years and above and the SC and ST pregnant women.

The limitation of cash assistance for institutional delivery is as follows:

1. In low performing states: All births, delivered in health centre, government or accredited, private health institutions will get the benefit.

2. In high performing states the benefit is only up to 2 live births.

ASHA package is available in all low performing states. North-east states and in tribal districts of all states and UTs in rural areas it includes the following components:

(a) Cash assistance for referral transport for pregnant women to go to the nearest health centre for delivery (should not be less than Rs. 200/-
(b) Cash incentive - This should not be less than Rs. 200/- per delivery. ASHA should get her money after her post-natal visit to the beneficiary, and when the child has been immunized for BCG; and (c) Balance amount to be paid to ASHA in lieu of her services rendered by her. The payment should be made at the hospital/health institution itself.

The Yojana subsidizes the cost of caesarean section and for management of obstetric complications, up to Rs. 1500 per delivery to the government institutions, where government specialists are not in position.

In low performing and high performing states, all below poverty line pregnant women preferring to deliver at home, are entitled to cash assistance of Rs. 500 per delivery, regardless of age and number of children (1).

The year 2006-07 was declared as the year for institutional deliveries. During the year scope of the scheme was extended to the urban areas of high performing states and restriction of age and birth order were removed in the low performing states. The benefits of the scheme was also extended to all women belonging to 9C/ST families for institutional deliveries.

During the year 2012-13, about 1.66 crore pregnant women were benefitted from the scheme (1).
Vandemataram scheme

This is a voluntary scheme wherein any obstetric and gynaec specialist, maternity home, nursing home, lady doctor/MBBS doctor can volunteer themselves for providing safe motherhood services. The enrolled doctors will display Vandemataram logo at their clinic. Iron and Folic Acid tablets, oral pills, TT injections etc. will be provided by the respective District Medical Officers to the Vandemataram doctors. Clinical for free distribution to beneficiaries. The cases needing special care and treatment can be referred to the government hospitals, who have been advised to take due care of the patients coming with Vandemataram cards.

Safe abortion services

In India, abortion is a major cause of maternal mortality and morbidity and accounts for nearly 8.9 per cent maternal deaths. Majority of abortions take place outside authorized health services and/or by untrained and unskilled persons. Whether spontaneous or induced, abortion is a matter of concern as it may lead to complications. Under RCH-II following facilities are provided:

a. Medical method of abortion: Termination of early pregnancy with two drugs – Mifepristone (RU 486) followed by Misoprostol. They are considered safe under supervision, with appropriate counselling. Currently its use in India is recommended up to 7 weeks (49 days) of amenorrhea in a facility with provision for safe abortion services and blood transfusion. Termination of pregnancy with RU 486 and Misoprostol is offered to women under the preview of the MTP Act, 1971.

b. Manual Vacuum Aspiration (MVA): The department of family welfare has introduced Manual Vacuum Aspiration (MVA) technique in the family welfare programme. Manual Vacuum Aspiration is a safe and simple technique for termination of early pregnancy, makes it feasible to be used in primary health centers or comparable facilities, thereby increasing access to safe abortion services. The project of introducing the MVA technique has been piloted in coordination with FOCSI, WHO and respective state governments before being accepted for implementation by the Ministry of health and family welfare.

Village Health and Nutrition Day

Organizing Village Health and Nutrition Day once a month at anganwadi centre to provide antenatal/post-partum care for pregnant women, promote institutional delivery, health education, immunization, family planning and nutrition services etc.

Maternal death review

Maternal death review as a strategy has been spelt out clearly in the RCH-II. Maternal death audit, both facility and community based, is an important strategy to improve the quality of obstetric care and reduce maternal mortality and morbidity. Guidelines and tools for initiating maternal death review have been formulated.

Pregnancy tracking

The link between pregnancy related care and maternal morbidity is well established. RCH-II stresses the need for universal screening of pregnant women and providing essential and emergency obstetric care. Focussed antenatal care, birth preparedness and complication readiness, skilled attendance at birth, care within the first seven days etc. are the factors that can reduce the maternal mortality (3).

JANANI-SISHU SURAKSHA KARYAKRAM (JSSK)

Government of India launched the Janani-Shishu Suraksha Karyakram (JSSK) on 1st June 2011, a new national initiative, to make available better health facilities for women and child. The new initiatives provide the following facilities to the pregnant women (42):

- All pregnant women delivering in public health institutions have been granted free and pre-emptive delivery, including caesarean section. The entitlements include free drugs and consumables, free diet upto 5 days during normal delivery and up to 7 days for C-section free diagnostics, and free blood wherever required. This initiative would also provide for free transport from home to institution, between facilities in case of a referral and drop back home. Similar entitlements have been put in place for all aikshewains accessing public health institutions for treatment till 30 days after birth. The scheme has now been extended to cover the complications during ANC, PNC and also sick infants.

- The scheme is estimated to benefit more than 12 million pregnant women who access government health facilities for their delivery. Moreover, it will motivate those who still choose to deliver at their homes to opt for institutional deliveries.

Child health components

The strategy for child health care, aims to reduce under-five child mortality through interventions at every level of service delivery and through improved child care practices and child nutrition.

Nutritional rehabilitation centres (NRCs)

Severe acute malnutrition is an important contributing factor for most deaths among children suffering from common childhood illnesses such as diarrhoea and pneumonia. Deaths among these malnourished children are preventable, provided timely and appropriate actions are taken. NRCs are facility based units providing medical and nutritional care to severe acute malnourished (SAM) children under 5 years of age who have medical complications. In addition special focus is on improving the skill of mothers on child care and feeding practices so that the child continues to get adequate care at home. The services provided at the NRCs include (1):

- a. 24 hours care and monitoring of the child;
- b. Treatment of medical complication;
- c. Therapeutic feeding;
- d. Sensory stimulation and emotional care;
- e. Counselling on appropriate feed, care and hygiene; and
- f. Demonstration and practice-by-doing on the preparation of energy dense food using locally available, culturally acceptable and affordable food items.

Presently 872 NRCs are functional across 17 states/UTs with 9377 dedicated beds (1).

Integrating Management of Neonatal and Childbirth Illness (IMNCI)

IMNCI strategy is one of the main interventions under the RCH II/ NRHM. The strategy encompasses a range of interventions to prevent and manage the commonest major childhood diseases.
### Pre-service IMNCI
Pre-service IMNCI has been accepted as an important strategy to scale up IMNCI by Govt of India and is being included in the curriculum of medical colleges of the country. This will help in providing the much needed trained IMNCI manpower in the public and private sector.

### Facility based IMNCI (F-IMNCI)
F-IMNCI is the integration of the facility based care package with the IMNCI package, to empower the health personnel with the skill to manage new born and childhood illness at the community level as well as the health facility. It focuses on providing appropriate infant feeding management of the major causes of neonatal and childhood mortality such as asphyxia, sepsis, low birth weight, pneumonia, diarrhoea, malaria, meningitis and severe malnutrition in children. The master trainers at state and district level are paediatricians from tertiary hospitals and medical colleges.

### Facility based newborn care (43)
As more sick children are screened at the peripheries through IMNCI and referred to the health facilities, care of the sick newborn and child at CHCs, FRUs, district hospitals and medical college hospitals assumes priority. Equipping the facilities to provide the website level of care and simultaneously enhancing the capacity of the medical officers at these facilities to handle such cases thus becomes important. The setting up of SNCUs at district hospitals, stabilization units at CHCs, and newborn care corners at all facilities offering delivery facilities, is thus a key activity (3).

In the overall planning of facility based care it is important to understand the level of care that is provided at the various facility levels. The newborn care facilities at different levels are as follows:

<table>
<thead>
<tr>
<th>Health facility</th>
<th>All newborns at birth</th>
<th>Sick newborns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary health centre (PHC)/Sub-centre (SC)</td>
<td>Newborn care corner in labor rooms</td>
<td>Prompt referral identified at MCH level I</td>
</tr>
<tr>
<td>Community health centre (CHC)/First referral (FRU) identified at MCH Level II</td>
<td>Newborn care corner in labor rooms and in stabilization unit</td>
<td>Newborn care corner in operation theatre (SNRU)</td>
</tr>
<tr>
<td>District hospital identified as MCH Level III</td>
<td>Newborn care corner in labor room and in stabilization unit</td>
<td>Special newborn care unit</td>
</tr>
</tbody>
</table>

**Neonatal Care Corner (NBCC)**

NBCC is a space within the delivery room in any health facility where immediate care is provided to all newborns at birth. This area is MANDATORY for all health facilities where deliveries are conducted. As of March 2014, about 13,663 NBCCs are operational in the country (1).

**Newborn Stabilization Unit (NBSU)**

NBSU is a facility within or in close proximity of the maternity ward where sick and low birth weight newborns can be cared for during short periods. All FRUs/CHCs need to have a neonatal stabilization unit, in addition to the newborn care corner. It requires space for 4 bedded unit and two beds in post-natal ward for rooming-in. As of March 2014, 1,737 NBSUs are functional in the country.

### Special Newborn Care Unit (SNCU)
SNCU is a neonatal unit in the vicinity of the labor room which is to provide specialized care (all care except assisted ventilation and major surgery) for sick newborns. Any facility with more than 3,000 deliveries per year should have a special unit for district hospitals and some sub-district hospitals would fulfill this criteria.

The minimum recommended number of beds for an SNCU at a district hospital is 12. However, if the district hospital conducts more than 3,000 deliveries per year, 4 beds should be added for each 1,000 additional deliveries. A 12 bedded unit will require 4 additional auxiliary beds for the step down. As of March 2014, 507 SNCUs are functional in the country.

### Tracheal of sick newborns (43)
Tracheal is sorting of neonates to rapidly screen sick neonates for prioritizing management. Fig. 11 summarizes the process. An SNCU AND A PRF ARE FOR REFERRAL TO NBSU (43).

Newborn presenting with any of the following signs to a facility with neonatal stabilization unit requires admission for initial stabilization and transfer to SNCU:

- Apnea or gasping
- Respiratory distress (rate >70/min with severe retractions/grunt)
- Hypothermia <35.4°C
- Hyperthermia >37.5°C
- Cephalic cyanosis
- Shock (cold periphery with capillary filling time [CFT] 3 seconds and weak and fast pulse)
- Significant bleeding that requires blood or component transfusion

Newborns who after assessment and stabilization, can be managed at stabilization unit:

- Newborns with respiratory distress, having respiratory rate 60-70/min without grunting or retractions (for observation and oxygen therapy)
- Newborns with gestation less than 34 weeks or weight <1800 g (for observation and assisted feeding)
- Newborns with hypothermia and hyperthermia who are haemodynamically stable after initial stabilization
- Newborns with jaundice requiring phototherapy
- Neonates with sepsis who are haemodynamically stable, for observation and antibiotic therapy.

* Others would require referral to an SNCU after stabilization, if an SNCU and appropriate referral is available in the district.

### B. CRITERIA FOR ADMISSION TO SNCU (43)
Criteria for admission to SNCU and criteria for transfer to step-down unit and discharge are as follows:

1. Any newborn with following criteria should be immediately admitted to the SNCU:
   - Birth weight <1800 g or gestation <34 weeks
   - Large baby (>4.0 kg)
   - Perinatal asphyxia
   - Apnea or gasping
   - Failure to feed
   - Respiratory distress (rate >60/min or grunt/ retractions)
   - Severe jaundice (appears <24 hr/stains palms and soles/lasts>2 weeks)
   - Hypothermia <35.4°C, or hyperthermia (>37.5°C)
   - Central cyanosis
Triage of a sick or at-risk newborn who presents at SNCU

- Hypothermia (temp <36°C)
- Apnea or gasping respiration
- Severe respiratory distress (rate >70, severe retractions, grunting)
- Central cyanosis
- Shock (cold periphery, CFT>3 secs, weak and fast pulse)
- Coma, convulsions or encephalopathy

Classify as emergency signals
Initiate emergency treatment

- Cold stress (temp 36.4°C-36°C)
- Respiratory distress (rate >60, no retractions)
- Irritable/irritable/littery
- Abdominal distension
- Severe jaundice
- Severe pallor
- Bleeding from any sites
- Major congenital malformations
- Weight less than 1800 g or more than 4 kg

Classify as priority signals
Assess and act rapidly

- Transitional crises
- Possetting
- Minor birth trauma
- Superficial infections
- Minor malformations
- Jaundice
- All cases not categorized as emergency or priority

Classify as non-urgent signals
Assess and counsel

Newborns classified as "Emergency" require urgent intervention and emergency measures. All such newborns will be admitted to SNCU after initial stabilization.

Newborns classified as "Priority" are sick and need rapid assessment and admission to SNCU.

Newborns classified as non-urgent do not require urgent attention, but require further assessment and counseling.

FIG. 11

II. Criteria for transfer from SNCU to the Step-Down
- Newborn whose respiratory distress is improving and does not require oxygen supplementation to maintain saturation
- Newborn on antibiotics for completion of duration of therapy
- Low birth weight newborn (less than 1860 g), who are otherwise stable (for adequate weight gain)
- Newborn with jaundice requiring phototherapy but otherwise stable
- Newborn admitted for any condition, but are now thermodynamically and hemodynamically stable

III. Criteria for discharge from SNCU
- Newborn is able to maintain temperature without radiant warmer
- Newborn is thermodynamically stable (normal CFT, strong peripheral pulse)
- Newborn accepting breast feeds well
- Newborn has documented weight gain for 3 consecutive days; and the weight is more than 1.5 kg
- Primary illness has resolved

In addition to the above, mother should be confident of taking care of the newborn at home.

HOME BASED NEWBORN CARE (HBNC) (44):

Home based newborn care is aimed at improving newborn survival. The strategy of universal access to home based newborn care must complement the strategy of institutional delivery to achieve significant reduction in postpartum and neonatal mortality and morbidity. The providers of service include anganwadi workers, ANM, ASHA and the medical officer. However, ASHA is the main person involved in home based newborn care.

The major objective of HBNC is to decrease neonatal mortality and morbidity through:
1. The provision of essential newborn care to all newborns and the prevention of complications.
2. Early detection and special care of preterm and low birth weight newborns.
3. Early identification of illness in the newborn and provision of appropriate care and referral.
4. Support the family for adoption of healthy practices and build confidence and skills of the mother to safeguard her health and that of the newborn.

The responsibilities of ASHA for home based newborn care are as follows (49):

1. Mobilize all pregnant mothers and ensure that they receive the full package of antenatal care.

2. Undertake birth planning and birth preparedness with the mother and family to ensure access to safe delivery.

3. Provide newborn care through a series of home visits which include the skills for:
   a. Weighing the newborn,
   b. Measuring newborn temperature,
   c. Ensuring warmth
   d. Supporting exclusive breast-feeding by teaching the mother proper positioning and attachment for breastfeeding and ensuring that the breastfed baby is given a warm and comfortable environment.
   e. Diagnosing and counselling in case of problems with breast-feeding,
   f. Promoting hand-washing,
   g. Providing skin, cord and eye care,
   h. Health promotion and counselling mothers and ismilies on key messages on newborn care which includes discouraging unhealthy practices such as easy bathing, and bottle feeding.
   i. Ensuring prompt identification of sepsis or other illnesses.

4. Assessing if the baby is high-risk (preterm or low birth weight), through the use of protocols and managing such LBW or preterm babies through:
   a. Increasing the number of home visits,
   b. Monitoring weight gain,
   c. Supporting and counselling the mother and family to keep the baby warm and enabling frequent and exclusive breast-feeding.

5. Detect signs and symptoms of sepsis, provide first level care and refer the baby to an appropriate centre. If the family is unable to go, ASHA should ensure that the ANM visits sick newborn on a priority basis.

6. Recognize postpartum complications in the mother and refer appropriate care.

7. Counsel the couple for family planning.

8. Provide immediate newborn care, in case of those deliveries that do not occur in institutions (home deliveries and deliveries occurring on the way to the institution).

ASHA will make visits to all newborns according to specified schedule up to 42 days of life. The schedule of visit is as follows:

b. Seven visits in the case of home delivery (Day 1, 3, 7, 14, 21, 28 and 42).

c. In cases of Caesarean section delivery, where the mother returns home after 5-6 days, ASHAs are entitled to full incentive of Rs. 250 if she completes all five visits starting from Day 7 to Day 42.

d. In cases when a newborn is discharged from SNCU, ASHAs are eligible to full incentive amount of Rs. 250 for completing the remaining visits. In addition, ASHAs are also eligible for an incentive of Rs. 50 for monthly follow-up of low birth weight babies and newborns discharged from SNCU as approved by M O S of the National Health Mission on December 6th, 2013). The low birth weight are followed up for two years and SNUC discharged babies for one year.

e. In cases where the woman delivers at her maternal house and returns to her husband’s house, two ASHAs undertake the HBNC visits, i.e., one at maternal house immediately after delivery, and another one at husband’s house when the newborn returns home or vice versa. In such cases the HBNC incentive of Rs. 250 can be divided into two parts in a way that each ASHA who completes 3 visits or more is entitled to Rs. 125. In these instances, if an ASHA undertakes less than 3 visits, she would not be entitled to HBNC incentive.

f. In cases of twin or triple the incentive amount for ASHA would be two times of the regular HBNC incentive of Rs. 250/- (i.e., Rs. 500/-) or three times of Rs. 250/- (i.e., Rs. 750/-) respectively.

The incentive paid is paid to ASHA on 45th day subject to the following:

a. Record of birth weight in the mother and child protection card;

b. Immunization of newborn with BCG, first dose of OPV, Hep B and DPT/pentavalent vaccine and entry into the mother and child protection card;

c. Registration of birth;

d. Both mother and newborn are safe until 42nd day of delivery.

Navjot Shishu Suraksha Karyakram (NNSK)

NNSK is a programme aimed to train health personnel in basic newborn care and resuscitation. It has been launched to address care at birth issue i.e. prevention of hypothermia, prevention of infection, early initiation of breast-feeding and basic newborn resuscitation. The focus of the new initiative is to have a trained health person in basic newborn care and resuscitation unit at every delivery point (6).

Integrated management of neonatal and childhood illness (IMNCI)

Integrated management of childhood illness (IMCI)

The extent of childhood morbidity and mortality caused by diarrhoea, ARI, malaria, measles and malnutrition is substantial. Most sick children prevent with signs and symptoms of more than one of these conditions. This overlap means that a single diagnosis may not be possible or appropriate, and treatment may be complicated by the need to combine for several conditions. An integrated approach to manage sick children is, therefore, necessary. IMCI is a strategy for an integrated approach to the management of childhood illness as it is important for child health programmes to look beyond the treatment of a single disease. This is cost effective and emphasizes prevention of disease and promotion of child health and development besides provision of standard case management of childhood illness.

In the Indian context this strategy is quite pertinent considering the recent evidence from NFHS-III report highlighting that ARI (17 percent), diarrhoea (13 percent), fever (27 percent) and under-nutrition (43 percent) were the commonest morbidities observed in the children aged under 3 years. Coverage of measles vaccination in children between 12-23 months is also low. An integrated approach to address these major childhood illnesses seems to be an effective strategy to promote child health in this country. The line of action is as shown in Fig. 12.
The Indian version of IMCI has been renamed as Integrated Management of Neonatal and Childhood Illness (IMNCI). It is the central pillar of child health interventions under the RCH II strategy. The major highlights of the Indian adaptation are:

- Inclusion of 0–7 days age in the programme;
- Incorporating national guidelines on malaria, anaemia, vitamin A supplementation and immunization schedule;
- Training of the health personnel begins with sick young infants up to 2 months;
- Proportion of training time devoted to sick young infant and sick child is almost equal; and
- Skill based.

For more details please refer to page 576, chapter 9.

IMNCI strategy is one of the main interventions under RCH II/ERHM. It focuses on preventive, promotive and curative aspects of the programme. The objective is to implement the IMNCI package at the level of household, and through ANMs at sub-centre level; through medical officers, nurse and LHWs at PHCs level.

Rashtriya Bal Swasthya Karyakram (RBK) (46)

RBK is a new initiative launched in February 2013. It includes provision for Child Health Screening and Early Intervention Services through early detection and management of 4 Ds, prevalent in children. These are defects at birth, diseases in children, deficiency conditions and development delays including disabilities. An estimated 27 crore children in the age group of 0–18 years are expected to be covered across the country in a phased manner.

Child Health Screening and Early Intervention Services under NRHM envisage to cover 30 identified health conditions for early detection, free treatment and management. Based on the high prevalence of diseases like hypothyroidism, sickle cell anaemia and beta thalassaemia in certain geographical pockets of some states/UTs, and availability of testing and specialized support facilities, these states and UTs may incorporate them as part of this initiative. The health conditions are as shown in Table 12.

Source: (46)
Programme Implementation

1. For newborn:
   - Facility based newborn screening at public health facilities, by established health teams.
   - Community based newborn screening at home through ASHA for newborn till 6 weeks of age during home visits.

2. For children 6 weeks to 6 years:
   - Anganwadi center based screening by dedicated Mobile Health Teams.

3. For children 6 years to 18 years:
   - Government and Government aided school based screening by dedicated Mobile Health Teams.

Facility based newborn screening

This includes screening of birth defects in institutional deliveries at public health facilities, especially at the designated delivery points by ANMs, Medical Officers/ Gynecologists. Existing health service providers at all designated delivery points will be trained to detect, register report and refer birth defects to the District Early Intervention Centre in District Hospitals.

Community based newborn screening (age 0–6 weeks) for birth defects

Accredited Social Health Activists (ASHAs) during home visits for newborn care will use the opportunity to screen the babies born at home and the institutions till 6 weeks of age. ASHAs will be trained with simple tools for detecting gross birth defects. Further ASHAs will mobilize caregivers of children to attend the local Anganwadi Centers for screening by the given Mobile Health Teams. For performing the above additional tasks, she would be equipped with a tool kit consisting of a pictorial reference book having self-explaining figures for identification of birth defects. Suitable performance based incentive may also be provided to ASHAs. In order to ensure improved outcome of the screening programme by Mobile Health Teams, ASHAs will give priority to the children with low birth weight, underweight and children from households known to have any chronic illness (e.g., tuberculosis, HIV, haemoglobinopathy etc.). Line lists maintained by the ANMs and ANMs would also be used to mobilize children.

Screening of children aged 6 weeks to 6 years attending Anganwadi Centres

Children in the age group 6 weeks to 6 years of age will be examined in the Anganwadi Centres by dedicated Mobile Health Teams.

Screening of children enrolled in Government and Government aided schools

For children in the age group 6 to 18 years, who will be screened in Government and Government aided schools, the block will be the hub of activity for the programme. At least three dedicated Mobile Health Teams in each block will be engaged to conduct screening of children. Villages within the jurisdiction of the blocks would be distributed amongst the mobile health teams. The number of teams may vary depending on the number of Anganwadi Centres, difficult to reach areas and children enrolled in the schools. The screening of children in the Anganwadi Centres would be conducted at least twice a year and at least once a year for school children to begin with.

In RCH Phase II the other interventions of RCH Phase I, e.g., additional ANMs, public health nurse, private anesthetists, safe motherhood consultants, 24 hours delivery services as PHCs and CHCs, referral transport, integrated financial envelope, RCH camps, training of Dari, border district cluster strategy, and intervention for newborn care and child health (immunization, control of ARI and diarrhoea, vitamin A and iron supplementation etc.) will continue.

The quality indicators used to monitor and evaluate RCH programme through monthly reports are:

1. Number of antenatal cases registered — total and at least 12 weeks;
2. Number of pregnant women who had 3 antenatal check-ups;
3. Number of high-risk pregnant women referred;
4. Number of pregnant women who had two doses of tetanus toxoid injection;
5. Number of pregnant women under prophylaxis and treatment for anaemia;
6. Number of deliveries by trained and untrained birth attendant;
7. Number of cases with complications referred to PHC/ FBU;
8. Number of newborn born with birth weight recorded;
9. Number of newborn given 3 postnatal check-ups;
10. Number of RUTF cases detected, treated and referred;
11. Number of children fully immunized;
12. Number of adverse reactions reported after immunization;
13. Number of cases of ARI and diarrhoea under 5 years treated, referred PHC/ FBU and deaths; and
14. Number of cases motivated and followed up for contraception.

REPRODUCTIVE, MATERNAL, NEWBORN, CHILD AND ADOLESCENT HEALTH (RMNCH+A) STRATEGY, 2013

In June 2012, the Government of India, Ethiopia, USA and the UNICEF convened the Global Child Survival Call to Action: A Promise to Keep! summit in Washington, DC to energize the global fight to end preventable child deaths through targeted interventions in effective, life-saving services for children. More than 80 countries gathered at the Call to Action to endorse a commitment to reduce child mortality by 20% by 2015 (48). Eight months after the event, in February 2013, the Government of India held its own historic Summit on the Call to Action for Child Survival, where it launched “A Strategic Approach to Reproductive, Maternal, Newborn, Child, and Adolescent Health (RMNCH+A) in India.” Since that time, RMNCH+A has become the heart of the Government of India’s flagship public health programme, the National Health Mission (49).

With support from USAID and its Maternal Child Health Integrated Programme (MCHIP), as well as from UNICEF, UNFPA, NPI and other development partners, the Government of India has taken important steps to introduce and support RMNCH+A implementation. This approach is likely to succeed given that India already has a community based programme with presence of 8.7 lakh ASHA workers, as well as the three tiered health system in place. These provide a strong platform for delivery of services. This integrated strategy can potentially promote greater efficiency while reducing duplication of resources and efforts in the ongoing programme.
The RMNCH+A strategy is based on provision of comprehensive care through the five pillars, or thematic areas, of reproductive, maternal, newborn, child, and adolescent health, and is guided by central tenets of equity, universal care, entitlement, and accountability. The 'plus' within the strategy focuses on:

- Including adolescence for the first time as a distinct life stage;
- Linking maternal and child health to reproductive health, family planning, adolescent health, HIV, gender, preconception and prenatal diagnostic techniques;
- Linking home and community-based services to facility-based care;
- Ensuring linkages, referrals, and counter-referals between and among health facilities at primary (primary health centre), secondary (community health centre), and tertiary levels (district hospital) and, also, in the community.

In developing the RMNCH+A strategy, the aim is to reach the maximum number of people in the remotest corners of the country through a continuum of services, in a constant innovation, and routine monitoring of interventions. In rolling out the new strategy, the emphasis is on high impact interventions in each of the five thematic areas of reproductive, maternal, newborn, child, and adolescent health, and then to focus its efforts, and those of its development partners, on improving the coverage and quality of those interventions in 184 high-priority districts (HPDs) across India. Guidelines and tools were developed and policies were adjusted.

1. High-Priority Districts: The RMNCH+A strategy addresses India’s inter-state and intra-district variations. The districts with relatively weak performance against RMNCH+A indicators were identified. Uniform and clearly defined priorities were used to identify 166 high-priority districts across all 29 states. The RMNCH+A approach is a conscious articulation of the GOI’s commitment to tailoring programmes to meet the needs of previously underserved groups, including adolescents, urban poor, and tribal populations.

2. Management tools and job aids: The RMNCH+A 5x5 matrix identifies five high-impact interventions across each of the five thematic areas, five cross-cutting and health systems strengthening interlinkages, and, the minimum essential commodities across each of the thematic areas. The 5x5 matrix as shown in Fig. 13 is an important tool for explaining the strategy in simple terms, organizing technical support, and monitoring progress with the states and high-priority districts.

Reproductive Health
- Focus on spacing methods, particularly PP/EDC at high risk and last facility.
- Focus on intrauterine SCID at all facilities including subcentres on fixed days.
- Home delivery/ Continuation (HDC) and Ensuring Staging at Birth (ESB) through ASHAs.
- Ensuring access to Pregnancy testing kits (PTK, 'Newbirth Kit') and strengthening comprehensive abortion care services.
- Maintaining quality sterilization services.

Maternal Health
- Use NICST to ensure early registration of pregnancy and full ANC.
- Detect high risk mothers; create a list including severely anaemic mothers and ensure appropriate management.
- Equip delivery points with highly trained HR and ensure equitable access to emergency obstetric care (EOC) facilities; Add MCH wings as per need.
- Review maternal, infant, and child deaths for corrective actions.
- Identify villages with high numbers of home deliveries and distribute Misoprostol to selected women in 8th month of pregnancy/or consumption during 3rd stage of labour; Incentive ASMs for home deliveries.

Newborn Health
- Early initiation and exclusive breast-feeding.
- Home based newborn care through ASHA.
- Essential Newborn Care and resuscitation services at all delivery points.
- Special Newborn Care Units with highly trained human resources; and other infrastructure.
- Community level use of Gentamicin by ANMs.

Child Health
- Complimentary feeding, IFA supplementation and focus on nutrition.
- Diarrhoea management at community level using ORS and Zinc.
- Management of tuberculosis.
- Full Immunization coverage.
- Ration, nutrition and health benefits.
- BSBI (RBSK); screening of children for 4D (birth defects, development delays, deficiencies and disease) and its management.

Adolescent Health
- Address teenager pregnancy and increase contraceptive prevalence in adolescents.
- Introduce community based services through peer educators.
- Strengthen ARSH Clubs.
- Roll out National IEC Plus Initiative including weekly IFA supplementation.
- Promote menstrual hygiene.

Health System Strengthening
- Case load based deployment of HR at all levels.
- Ambulances, drugs, diagnostics, reproductive health commodities.
- Health education, demand promotion & behavioural change communication.
- Supportive supervision and use of data for monitoring and review, including feedbacks based on MMS.
- Public grievance redressal mechanism, client satisfaction and patient safety through all Lady Health and quality assurance.

Cross Cutting Interventions
- Being down out of pocket expenses by ensuring ISSK, RBSK and other free entitlements.
- ANMs & Nurses to provide specialised and quality care to pregnant women and children.
- Address social determinants of health through convergence.
- Focus on un-served and underserved villages, urban slums and blocks.
- Introduce difficult area and performance based Incentives.

FIG. 13

5 x 5 matrix for high impact RMNCH+A interventions
To be implemented with High Coverage and High Quality
Goals and Targets (37)

Taking into account the progress made so far in maternal and child health, it is pertinent to establish the goals and targets for the implementation phase 2012-2017, after considering the main reasons for mortality and interventions proven to have an impact on them. The 12th Five Year Plan has defined the national health outcomes and the three goals that are relevant to RMNCH+A strategic approach are as follows:

- Reduction of Infant Mortality Rate (IMR) to 25 per 1,000 live births by 2017.
- Reduction in Maternal Mortality Ratio (MMR) to 100 per 100,000 live births by 2017.
- Reduction in Total Fertility Rate (TFR) to 2.1 by 2017.

For achieving these goals, variable increase in the coverage level for key interventions are required. These are defined in the Table 13.

While the country aims to set one collective goal towards reducing preventable maternal, newborn and child deaths by 2017, it is increasingly becoming apparent that there is a varied and unequal rate of progress within the states and districts. Therefore, state specific coverage targets should be established against existing baselines. The national and state 'scorecard' is being introduced as a tool to increase transparency and track progress against reproductive and maternal health and child survival indicators related with intervention coverage. For more details about the score cards please refer to page 466.

The implementation strategies of RMNCH+A (37)

The key interventions of RMNCH+A as a 'Continuum of Care' are as shown in Fig. 14. The set of interventions are those that have high impact on reducing mortality and improving survival. Most of these interventions have been part of the previous phase of NRHM. The effectiveness of these will be determined by the coverage achieved among the affected fraction of population as also the availability, acceptability, actual utilization of services and quality of services delivered.

Adolescent Health Programme (1, 37)

Taking cognizance of the diverse nature of adolescent health needs, a comprehensive adolescent health strategy has been developed. The priority under adolescent health include nutrition, sexual and reproductive health, mental health, addressing gender-based violence, non-communicable diseases and substance use. The strategy proposes a set of interventions (health promotion-prevention, diagnosis, treatment and referral) across levels of care. These inter-ventions and approaches work towards building protective factors that can help adolescents and young people develop 'resilience' to resist negative behaviours and operate at four major levels: individual, family, school and community by providing a comprehensive package of 'information, commodities and services'.

The priority interventions are as follows:

1. Adolescent nutrition; iron and folic acid supplementation.
2. Facility-based adolescent reproductive and sexual health services (ARSH) (Adolescent health clinics).
3. Information and counselling on adolescent sexual reproductive health and other health issues.
4. Menstrual hygiene.
5. Preventive health check-ups.

A. Adolescent Reproductive and Sexual Health programme (ARSH)

Adolescent Reproductive and Sexual Health programme (ARSH) focuses on reorganizing the existing public health system in order to meet service needs of adolescents. Steps

**TABLE 13**

Coverage targets for key RMNCH+A interventions for 2017

- Increase facilities equipped for perinatal care (designated as 'delivery points') by 100%.
- Increase proportion of all births in government and accredited private institutions at annual rate of 5.6% from the baseline of 61% (SRMS 2010).
- Increase proportion of pregnant women receiving antenatal care at annual rate of 6% from the baseline of 53% (CES 2009).
- Increase proportion of mothers and newborns receiving postnatal care at annual rate of 7.5% from the baseline of 45% (CES 2009).
- Increase proportion of deliveries conducted by skilled birth attendants at annual rate of 2% from the baseline of 76% (CES 2009).
- Increase exclusive breast-feeding rates at annual rate of 5.6% from the baseline of 35% (CES 2009).
- Reduce prevalence of under-five children who are underweight at annual rate of 5.5% from the baseline of 45% (NFHS-3).
- Increase coverage of these doses of combined diphtheria-tetanus-pertussis (DTPs) (2-23 months) at annual rate of 3.5% from the baseline of 7% (CES 2009).
- Increase ORS use in under-five children with diarrhea at annual rate of 7.2% from the baseline of 43% (CES 2009).
- Reduce unmet need for family planning methods among eligible couples. married and unmarried, at annual rate of 8.8 from the baseline of 21% (DHS 3).
- Increase met need for modern family planning methods among eligible couples at annual rate of 4.5% from the baseline of 47% (DHL 3).
- Reduce anemia in adolescent girls and boys (15-19 years) at annual rate of 6% from the baseline of 56% and 30%, respectively (NFHS-3).
- Decrease the proportion of total fertility contributed by adolescents (15-19 years) at annual rate of 3.8% per year from the baseline of 16% (NFHS-3).
- Raise child sex ratio in the 0-6 years age group at annual rate of 0.6% per year from the baseline of 914 (Census 2011).
Clinical

- Comprehensive abortion care
- RTI/STI care management,
- Perinatal (IU/TOC and
- Neonatal care)
- Postpartum (IU/TOC
- procedures)
- Adolescent health
- services

Pregnancy and child birth care
- Skilled obstetric care, immediate
delivery care and
- neonatal care
- Emergency obstetric care
- Preventing Perinatal-to-Child
- Transmissibility (PTICT) of HIV
- Puerperal sterilisation

Neonatal and child care
- Essential neonatal care
- Care of sick neonatal (NICU, NICU)
- Facility-based care of childhood illnesses (IMNCI)
- Care of children with acute
- malnutrition (MNC)
- Immunisation

Outreach/Sub-centre

Reproductive health care
- Family planning (including
- IUCD insertion, OCP and
- condoms)
- Prevention and
- management of STIs
- Pre-conception folic acid
- supplementation

Antenatal care,
- Full antenatal care package
- PPCTC

Postnatal care
- Early detection and
- management of illnesses
- in mother and newborn
- Immunisation

Child health care
- First level assessment
- care for newborns and
- childhood illnesses
- Immunisation
- Micro-nutrient
- supplementation

Family & Community

- Weekly IFA supplementation
- Information and counselling
on sexual reproductive
health and family planning
- Community-based promotion
and delivery of contraceptives
- Menstrual hygiene

- Counselling and preparation for
newborn care, breastfeeding,
and postnatal care
- Demand generation for
antenatal care and
institutional delivery
(JUS, JSSK)

- House-based newborn care and prompt referral
- (BNMC scheme)
- Antenatal care
- Infant and young Child Feeding (ICF)
- including exclusive breastfeeding and complementary feeding.
- Child health screening and early
- intervention services (0-18 years)
- Early childhood development
- Danger signs recognition and care-seeking for illness
- Use of ORS and Zinc in case of diarrhoea

Intersectional: Water, sanitation, hygiene, nutrition, education, empowerment

Adolescence/Pre-pregnancy Pregnancy Birth Newborn/postnatal Childhood

FIG. 14

Continuum of care across life cycle and different levels of health system

are being taken to ensure improved service delivery for adolescents during routine sub-centre clinics and also to ensure service availability on fixed days and timings at the Primary Health Centre, Community Health Centre and District Hospital levels. Core package of services includes promotive, preventive, curative and counselling services being made available for all adolescents – married and unmarried, girls and boys through adolescent friendly health clinics. ARSH programme envisages creating an enabling environment for adolescents to seek health care services through a spectrum of programmatic approaches:

- Facility based health services- Adolescent Friendly Health Clinics;
- Counselling-Dedicated ARSH and ICTC counselling;
- Community based interventions- Outreach activities,
- Capacity building for service providers.

1. Adolescent Friendly Health Clinics (AFHC): Though Adolescent Friendly Health Clinics, routine check-up at primary, secondary and tertiary levels of care is provided on fixed day clinics. At present 6,302 AFHCs are functional across the country providing services, information and commodities to more than 2.5 million adolescents for varied health related needs such as contraceptives provision, management of menstrual problems, RTI/STI management, antenatal care and anaemia.

ii. Facility based counselling services: Counselling services for adolescents on important issues such as nutrition, puberty, RTI/STI prevention and contraception, delaying marriage and childbearing, and concerns related to contraception, abortion services, pre-marital concerns, substance misuse, sexual abuse and mental health problems are being provided through recruitment and training of dedicated counsellors. At present 581 dedicated ARSH counsellors are providing comprehensive counselling services to adolescents across the country. In 23 States/UTs, 1439 ICTC counsellors have been enrolled to provide sexual and reproductive health counselling to adolescents.

iii. Outreach activities Outreach activities are being conducted in schools, colleges, teen clubs, vocational training centres, during Village Health Nutrition Day (VHND), health melas and in collaboration with self-
help groups to provide adequate and appropriate
information to adolescents in spaces where they	normally congregate.

B. Regular Iron and Folic Acid Supplementation (WIFS)
Ministry of Health and Family Welfare has launched the
Weekly Iron and Folic Acid Supplementation (WIFS)
Programme to meet the challenge of high prevalence and
incidence of anaemia amongst adolescent girls and boys.
The long-term goal is to break the intergenerational cycle of
anaemia, the short-term benefit is of a nutritionally
improved human capital. The programme, implemented
cross the country, both in rural and urban areas, will cover
10.25 crore adolescents. The key interventions under this
programme are as follows:
- Administration of supervised weekly iron-folic acid
supplements of 100 mg elemental iron and 500 µg folic acid
using a fixed day approach.
- Screening of target groups for moderate/severe anaemia
and referring these cases to an appropriate health facility.
- Biannual de-worming (Albendazole 400 mg), six months
apart, for control of helminths infestation.
- Information and counselling for improving dietary intake
and for taking actions for prevention of intestinal worm
infestation.

C. Menstrual Hygiene Scheme (MHS)
The Ministry of Health and Family Welfare has launched
scheme for promotion of menstrual hygiene among
adolescent girls in the age group of 10-19 years in rural
areas. This programme aims at ensuring that girls have
adequate knowledge and information about menstrual
hygiene and have access to high quality sanitary napkins
along with safe disposal mechanisms. Key activities under the
scheme include:
- Community-based health education and outreach in
the target population to promote menstrual health;
- Ensuring regular availability of sanitary napkins to the
adolescents;
- Sourcing and procurement of sanitary napkins;
- Storage and distribution of sanitary napkins to the
adolescent girls;
- Training of ASHA and nodal teachers in menstrual
health, and
- Safe disposal of sanitary napkins.

CARE DURING PREGNANCY AND CHILDBIRTH (37)
Pregnancy and childbirth are physiological events in the
life of a woman. Though most pregnancies result in normal
birth, it is estimated that about 15% percent may develop
complications, which cannot be predicted. Most of these
complications can be averted by preventive care, skilled care
at birth, early detection of risk, appropriate and timely
management of obstetric complications and postnatal care.
The delivery of services during pregnancy and childbirth
requires a strong element of continuum of care from
community to facility level and vice versa. While the
antenatal package, counselling and preparation for newborn
care, breastfeeding, birth and emergency preparedness
will mainly be delivered through community outreach; skilled
birth attendance one to be provided at health facilities,
primarily 24x7 PHC and FRU. These facilities are most likely
to be the one that have been designated as "delivery points" and
therefore have provision for full complement of RMCH
services. Following discharge from the health facilities,
mothers and newborns will be provided postnatal care
customized visits. Most of these services are already in
place.

The priority interventions are as follows (37):
1. Delivery of antenatal care package and tracking of
high-risk pregnancies.
2. Skilled obstetric care.
3. Immediate essential newborn care and resuscitation.
4. Emergency obstetric and newborn care.
5. Postpartum care for mother and newborn.
6. Postpartum IUCD and sterilisation.

NEWBORN AND CHILD CARE
The interventions in this phase of life mainly focus on
children under 5 years of age. Given below are the priority
child health interventions that are already in place under
NRHM.

Priority Interventions (37):
1. Home-based newborn care and prompt referral.
2. Facility-based care of the sick newborn.
3. Integrated management of common childhood
illnesses (diarrhoea, pneumonia and malaria).
4. Child nutrition and essential micronutrients
supplementation.
5. Immunization.
6. Early detection and management of defects at birth,
deficiencies, diseases and disability in children
0-18 years of age (Rashtriya Bal Swasthya Karyakram).

CARE THROUGH THE REPRODUCTIVE YEARS
Reproductive health needs to exist across the
reproductive years and therefore access to these services is
required in various life stages starting from the adolescence
phase. Reproductive health services include the provision
for contraceptives, access to comprehensive and safe
abortion services, diagnosis and management of sexually
transmitted infections, including HIV.

A new strategic direction has been developed for the
family planning programme, wherein it has been
repositioned to not only achieve population stabilisation but
also to reduce maternal mortality as also infant and child
mortality. A target-free approach based on unmet needs for
contraception; equal emphasis on spacing and limiting
methods; and promoting 'children by choice' in the context of
reproductive health are the key approaches to be adapted for
the promotion of family planning and improving
reproductive health.

These services will be delivered at home through
community outreach and at all levels of health facilities and
include adolescents and adults in the reproductive age
group.

Priority interventions (37):
1. Community-based promotion and delivery of
contraceptives.
2. Promotion of spacing methods (interval IUCD).
3. Sterilization services (vasectomies and tubectomies).
4. Comprehensive abortion care (includes MTP Act).
5. Prevention and management of sexually transmitted and reproductive infections (ST/RTI).

Delivery Points (37)

The provision of services for delivery care in a health facility generally serves as an important indicator to assess whether the facility is optimally functional or not. The concept of 'delivery point' emerges from this presumption. Among the health facilities designated as L1, L2 and L3, there are some facilities which are conducting deliveries above a minimum benchmark (minimum 1 normal delivery per month at L1; minimum 10 deliveries per month, including management of complications, at L2; minimum 20-50 deliveries per month including C-section at L3). These are designated as delivery points. According to the government mandate, these facilities should be the first to be strengthened for providing comprehensive RMNCH+ Services. This should be supported by a referral transport system that reaches the patient within 30 minutes of receiving a call and the health facility within the next 30 minutes. The long-term goal should be to establish and operationalize Basic Emergency Obstetric Care and Comprehensive Emergency Obstetric Care Centres as per the expected delivery load in the state and districts.

Maternal and Child Health (MCH) Wing (37)

Most health facilities, especially those at secondary and tertiary level are having high case load of pregnant women and newborn due to increase in institutional deliveries following launch of JSY and JSSR. Therefore, it has been decided that dedicated Maternal and Child Health Wigs will be established in high case load facilities with adequate provision of beds. The new MCH wings will be comprehensive units (30/50/100 bedded) with antenatal waiting rooms, labour wing, essential newborn care room, SNCU, operation theatre, blood storage units and a postnatal ward and an academic wing. This will ensure provision of emergency maternal and newborn care services as well as 48 hours stay, i.e. quality postnatal care to mothers and newborns (37).

SCORE CARD (37)

A. Health Management Information System – based dashboard monitoring system:

The choice of indicators for dashboard monitoring system are based on life cycle approach, and are as shown in Fig. 15.

1. Steps underway to include proportion

   - Pregnant women <19 yrs old to total women registered for ANC.
   - Home Based New born Care (HBNC) visit by ASHA to planned visits.
   - Children 9–11 months fully immunized to children 9–11 months due for immunization.
   - Children with diarrhoea who were treated with ORS to children reported with diarrhoea.
   - Children with diarrhoea who were treated with ORS and Zinc to children reported with diarrhoea.
   - Children discharged live from SNCUs to number of admissions in SNCUs.
   - Children with ARIs who received treatment to children reported with ARIs.

Proportion of:

- 1st Trimester registration to total ANC registration
- Pregnant women received 3 ANC to total ANC registration
- Pregnant women given 100 IFA to total ANC registration
- Cases of pregnant women with obstetric complications and attended to reported deliveries
- Pregnant women receiving TT2 or Booster to total ANC registration

Proportion of:

- Postpartum sterilization to total female sterilization
- Male sterilization to total sterilization
- IUD insertions in public plus private accredited institutions to all family planning methods (IUD plus permanent)

Proportion of:

- Neonates breast-fed within 1 hour to total live births
- Women discharged in less than 48 hours of delivery in public institutions to total number of deliveries in public institutions
- Newborn weighing less than 2.5 kg to newborns weighed at birth
- Newborns visited within 24 hrs of home delivery to total reported home deliveries
- Infants 0 to 11 months old who received measles vaccine to reported live births

FIG. 15
Choice of indicators for dash board
2. All India average for each indicator will be taken as the reference point.

3. States scores will be determined on the basis of the national average:
   - Positive scores from 1 to 4 for those above the national average (for positive indicators) and for those below the national average (for negative indicators).
   - Negative scores -1 to -4 for those below national average (for positive indicators) and for those above national average (for negative indicators).

4. All the indicator scores for each state will be consolidated as state score (all indicators have the same weightage).

5. States have been classified into four categories based on the state scores.

B. Survey based score card (37)

19 survey based outcome and coverage indicators related to health, nutrition and sanitation will be used for the score card. The indicators are as shown in Table 14.

<table>

</table>

Latest available data from national surveys will be taken into consideration including Sample Registration System, Comprehensive Rural Helath Survey, National Family Health Survey, Census, State Health Survey, Annual Health Survey.

All India average for each indicator will be taken as a reference point. States will be colour coded based on:
- Mortality indicators, nutrition, fertility: Green – less than 20% of the national average, Yellow – 20% below and above national average, Red – more than 20% of the national average.
- Remaining indicators: Green – more than 20% of the national average, Yellow – 20% below and above the national average, Red – less than 20% of the national average.

The scorecard will be updated as and when (every 1-2 years) new survey data is available.

INDIA NEWBORN ACTION PLAN (INAP)

In the past two decades, there has been remarkable progress in the survival of mother and children beyond the newborn period. Presently, the newborn health has captured the attention of the policy makers and two important milestones in this direction have been the National Rural Health Mission and the Reproductive, Maternal, Newborn, Child and Adolescent Health Strategy. RMNCH+A Strategy, INACH has provided unprecedented attention and resources for newborn health. By adopting RMNCH+A strategy in 2013, the country observed a paradigm shift in its approach towards health care. Newborn health occupies a central stage in the overall strategy as all the inter-linkages between various components have the greatest impact on the mortality and morbidity rates of the newborn.

In India, Newborn Action Plan (INAP) developed in response to the global Every Newborn Action Plan (ENAP), was launched in June 2014. The plan outlines a targeted strategy for accelerating the reduction of preventable newborn deaths and stillbirths in the country. INAP defines the latest evidence on effective interventions which will not only help in reducing the burden of stillbirths and neonatal mortality, but also maternal deaths. The goal is to attain “Single Digit Neonatal Mortality rate by 2030” and “Single Digit Stillbirth rate by 2030.”

The INAP will be implemented within the existing RMNCH+A framework, and guided by the principles of integration, equity, gender, quality of care, convergence, accountability and partnerships. Its strength is built on six pillars of intervention packages impacting stillbirths and newborn health, which includes: (a) Pre-conception and antenatal care; (b) Care during labour and childbirth; (c) Immediate newborn care; (d) Care of the healthy newborn; (e) Care of small and sick newborn; and (f) Care beyond newborn survival. For effective implementation, a systematic plan of monitoring and evaluation has been developed with a list of dashboard indicators (33).

The interventions under the National Health Mission focussing on newborns are shown in Table 15.

### Strategic Intervention Packages (33)

The interventions are grouped in six packages, corresponding to the various life stages of the newborn. It is estimated that high coverage of available intervention packages can prevent almost three-quarters of the newborn deaths, one-third of stillbirths and half of the maternal deaths by 2025.

The interventions have been categorized as:

- **Essential (E), to be implemented universally;**
- **Situational (S), implementation dependent on epidemiological context;**
- **Advanced (A), implementation based on health-system capacity of the state/district.**

The states are urged to develop their own action plans based on the six packages described below:

1. **Pre-conception and antenatal care**

   Health interventions must start well before conception and their impact on the neonatal and stillbirth outcome requires equivalent consideration. The importance of antenatal care for improved neonatal and perinatal outcome is well established; however, coverage of a few salient interventions needs increased attention (e.g., use of long lasting insecticide treated nets and intermittent preventive treatment of malaria, antenatal syphilis screening combined with treatment and increased emphasis on early detection, and prompt treatment of complications in pregnancy such as pre-eclampsia, type-2 diabetes).

The strategic interventions for pre-conception and antenatal care for newborns are given below.
Pre-conception and antenatal care interventions package

Family and community
1. Reproductive health & family planning (E)
   - Adolescent reproductive health
   - Delaying age of marriage and first pregnancy
   - Birth spacing
2. Nutrition-related interventions (E)
   - Balanced protein and calorie supplementation
   - Peri-conceptional folic acid
   - Maternal calcium supplementation
   - Multiple micronutrient supplementation
   - Nutrition counseling
3. Counselling and birth preparedness (E)
4. Prevention against malaria (S)

Outreach/Sub-centre
5. Antenatal screening for anaemia and hypertensive disorders of pregnancy (PIH, pre-eclampsia, eclampsia) (E)
6. Antenatal screening for malaria (S)
7. Prevention and management of mild to moderate anaemia (E)
8. Maternal tetanus immunization (E)
9. Adolescents friendly health services (nutrition and reproductive health counseling) (E)
10. Infant I&D insertion (E)

Health facility
11. Antenatal screening and management of severe anaemia, hypertensive disorders of pregnancy (PIH, pre-eclampsia, eclampsia), genital diabetes, syphilis (E)
12. Antenatal screening and management of hyperemesis, hepatitis E, HIV, malaria (S)
13. Adolescent friendly health clinics (as per RRSK guideline) (E)
14. Postpartum family planning services including IPPF/IUD insertion (E)
15. Prevention of Rh disease using anti-D immunoglobulin (S)

2. Care during labour and childbirth

Intrapartum complications and preterm births remain a challenge to the neonatal survival. Care during labour and childbirth have the potential to reduce stillbirths by 3rd. It is important to emphasize that BEmOC can reduce intrapartum-related neonatal deaths by 40% and CEmOC can also reduce newborn mortality by 40%, whereas skilled attendance at birth alone without access to the emergency component has a smaller effect at 25%. Care at childbirth also has additional benefits on child survival, improved growth, reduced disability and non-communicable diseases.

Antenatal corticosteroids use to manage preterm labour not only reduces neonatal deaths by 31%, but this intervention is also associated with reduced need of specialized care for newborns, such as ventilators, etc. Antibiotics administration for pre-mature rupture of membranes (PROM) reduces early-onset postnatal sepsis. Clean birth practices especially hand-washing with soap and water by birth attendant has been found to reduce mortality due to sepsis in births at home (10%), facilities (27%), and during postnatal period (40%).

The strategic interventions for care during labour and child birth are given below:

Family and community
1. Skilled birth attendance (E)
2. Clean birth practices (E)

Outreach/Sub-centre
3. Identification of complications and timely referral (E)
4. Pre-emptive dose by ANM (E)
   - Antenatal corticosteroids in preterm labour
   - Antibiotics for premature rupture of membranes

Health facility
5. Emergency obstetric care (E)
   - Basic and comprehensive
6. Management of preterm labour (E)
   - Antenatal corticosteroids in preterm labour
   - Antibiotics for premature rupture of membranes

3. Immediate newborn care

Immediate care is the basic right of every newborn baby. This package includes interventions such as immediate drying and stimulation, provision of warmth, hygienic care, early initiation of breast-feeding, and administration of vitamin K. For babies who do not breathe at birth, neonatal resuscitation is a crucial life-saving intervention. Resuscitation training of providers in facilities reduces intrapartum-related neonatal deaths and early neonatal deaths substantially. Hyperthermia is a risk factor for neonatal mortality, especially in cases of preterm and low birth weight babies. All steps should be taken to prevent and manage hyperthermia, and rooming-in of babies with mother must be universally practiced. Delayed cord clamping in newborns, including pre-term babies is associated with decreased risk of anemia and intraventricular haemorrhage. Administration of vitamin K at birth prevents haemorrhagic disease of newborn.

The strategic interventions for immediate newborn care are given below:

Immediate newborn care

Family and community
1. Delayed cord clamping (E)
2. Interventions to prevent hypothermia (E)
   - Immediate drying
   - Head covering
   - Skin-to-skin care
   - Delayed bathing
3. Early initiation and exclusive breast-feeding (E)
4. Hygiene to prevent infection (E)

Outreach/Sub-centre
5. Vitamin K at birth (E)
6. Neonatal resuscitation (E)

Health facility
7. Advanced neonatal resuscitation (E)
4. Care of healthy newborn

Evidence shows that community-based interventions can significantly improve child survival. A large number of ASHAs have been trained to perform various preventive and promotive health activities, such as counselling of mothers on breast-feeding, complementary feeding, immunization, care-seeking, promoting nutrition, sanitation, and safe drinking water, etc. Despite the significant increase in institutional deliveries, home deliveries persist to about 25% to 40% in pockets across states. Even in cases of institutional deliveries, most women tend to return home within a few hours after delivery. For women who stay at the institution for 48 hours or more, it is also important to provide care to the neonate at home for the remaining critical days of the first week and up to the 42nd day of life. Home visitation by ASHAs can contribute significantly to delivery of interventions with focus on the newborn period. Regular and timely contacts with the newborn are essential for ensuring continued exclusive breast-feeding, appropriate immunization, and care-seeking of children at danger signs.

The interventions for care of healthy newborn are given below:

Care of healthy newborn

5. Care of small and sick newborn

Specific interventions for small and sick newborns include Kangaroo mother care (KMC). KMC involves package of early and continuous skin-to-skin contact, breast-feeding support, and supportive care in stable newborns weighing less than 2000 gm. KMC can be practiced even at home, thus improving chances of newborn survival.

Strategic interventions for care of small and sick newborn include:

- Care of small and sick newborn

<table>

</tbody>
</table>
For sake of better understanding, we have divided the content into two sections.
The major objectives of the programme are as follows (4):
- Prevent and control common NCDs through behaviour and lifestyle changes.
- Expand early diagnosis and management of common NCDs.
- Build capacity at various levels of health care for prevention, diagnosis and treatment of common NCDs.
- Train human resource within the public health set-up with doctors, paramedics and nursing staff to cope with the increasing burden of NCDs, and
- Establish and develop capacity for palliative & rehabilitative care.

The programme is to be implemented in 26,000 sub-centres and 700 community health centres (CHCs) in 100 districts across 21 States/UTs and the strategies include promoting healthy lifestyle through massive health education and mass media efforts at country level, opportunistic screening of persons above the age of 30 years, establishment of Non-Communicable Disease (NCD) Clinic at Community Health Centre (CHC) and District level, development of trained manpower and strengthening of tertiary level health facilities. For long-term sustainability of the programme, service delivery will be through existing public health infrastructure and systems. The various approaches such as mass media, community education and interpersonal communication will be used for behaviour change focusing on the following messages:
- Increased intake of healthy foods
- Increased physical activity
- Avoidance of tobacco and alcohol
- Stress management.

Activities at Sub-Centre
Health promotion for behaviour and lifestyle change will be carried out by organizing various camps, interpersonal communications, posters, banners, etc. Opportunistic screening of population above 30 years will be carried out using BP measurement and blood glucose by strip method. The suspected cases of diabetes and hypertension will be referred to CHCs of higher health facility for further diagnosis and management. For screening of diabetes, glucometer optimum speed, optium test strips and auto disabled lancet are being procured at central level and provided to the concerned states as per their requirements from time to time.

Activities at CHC
NCD clinic at CHC shall do the diagnosis by required investigations like blood sugar measurement, lipid profile, ultrasound, X-ray and ECG etc., management and stabilization of common CVD, diabetes and stroke cases (out-patient as well as in-patients). One of the nurses appointed under the programme shall undertake home visits for bedridden cases, supervise the work of health workers and attend monthly clinics being held in the villages on a random basis. Complicated cases of diabetes, high blood pressure, etc. shall be referred from CHC to the district hospital for further investigations and management.

Activities at district hospital
NCD clinic at district hospital shall screen persons above the age of 30 years for diabetes, hypertension, cardiovascular diseases etc. to identify individuals who are at a high-risk of developing diabetes, hypertension and CVDs warranting further investigation/action. Detailed investigation will be done in respect of persons those who are at high-risk of developing NCDs on screening and those who are referred from CHCs. They shall provide regular management and annual assessment of persons suffering from cancer, diabetes and hypertension. People with established cardiovascular diseases shall also be managed at district hospital. They shall provide home-based palliative care for chronic, debilitating and progressive patients. Apart from clinical services, district hospitals shall be involved in promotion of healthy lifestyle through health education and counselling to the patients and their attendants.

Urban health check-up scheme for diabetes and high blood pressure
The scheme has the following objectives:
1. To screen urban slum population for diabetes and high blood pressure.
2. To create database for prevalence of diabetes and high blood pressure in urban slums.
3. To sensitize the urban slum population about healthy lifestyle.

The blood sugar and blood pressure will be checked for all ≥30 years and all pregnant women of all age.

The NCD cells at the centre, state and district will implement and monitor the National Programme for Prevention and Control of Cancer, Diabetes, CVD and Stroke (NPCDCS) in various states. The national NCD cell has been established at the centre.

B. Cancer control under NPCDCS
Cancer is an important public health problem in India, with nearly 10 lakh new cases occurring every year in the country. It is estimated that these are 2.8 million cases of cancer in the country at any given point of time. With the objectives of prevention, early diagnosis and treatment, the national cancer control programme was launched in 1976–77. In view of the magnitude of the problem and gaps in the availability of cancer treatment facilities across the country, the programme was revised in 1984–85 and subsequently in December 2004. During 2010, the programme was integrated with National Programme on Prevention and Control of Diabetes, Cardiovascular Disease and Stroke. The objectives of the programme are:
- a. Primary prevention of cancers by health education;
- b. Secondary prevention i.e. early detection and diagnosis of common cancer such as cancer of cervix, mouth, breast and tobacco-related cancer by screening/self examination method; and
- c. Tertiary prevention i.e. strengthening of the existing institutions of comprehensive therapy including palliative care.

The schemes under the revised programme are:
1. Regional Cancer Centre Scheme
The existing regional cancer centres are being further strengthened to act as referral centres for complicated and difficult cases at the tertiary level. The time assistance of Rs. 3 crores during the plan period is provided to Regional Cancer Centres except TMH, Mumbai and IRCH (AIIMS) for strengthening and to the CNCI, Kolkata on the approved pattern of funding.
2. Oncology Wing Development Scheme

This scheme had been initiated to fill up the geographic gaps in the availability of cancer treatment facilities in the country. Central assistance is provided for purchase of equipment, which include a co-balt unit besides other equipment. A part of the grant can be used for the civil work but the manpower is to be provided by the concerned state government institution. The quantum of central assistance is Rs. 3 crores per institution under the scheme.

3. Decentralized NGO scheme

This scheme is meant for IEC activities and early detection of cancer. The scheme is operated by the nodal agencies and the NGOs are given financial assistance for undertaking health education and early detection activities of cancer.

4. IEC activities at central level

IEC activities at the central level are to be initiated in order to give wider publicity about the Anti Tobacco Legislation for discouraging consumption of cigarettes and other tobacco related products, and for creating awareness among masses about the ill effects of consumption of tobacco and tobacco related products. Under this scheme wider publicity would also be given about the rules being formulated for implementation of various provisions of the anti-tobacco legislation. November 7th is observed as National Cancer Awareness Day in the country.

5. Research and training

Training programmes, monitoring and research activities will be organized at the central level under this scheme. Following training manuals have been developed under the NCSCP for capacity building in cancer control at district level:

- a. Manual for health professionals
- b. Manual for cytology
- c. Manual for palliative care
- d. Manual for tobacco cessation

Cancer services under national programme for prevention and control of cancer, diabetes, CVD and stroke (6):

1. Common diagnostic services, basic surgery, chemotherapy and palliative care for cancer cases is being made available at 100 district hospitals.
2. Each district is being supported with Rs. 1.66 crores per annum for the following:
   - Chemotherapy drugs are provided for 100 patients at each district hospital.
   - Day care chemotherapy facilities is being established at 100 district hospitals.
   - Facility for laboratory investigations including mammography is being provided at 100 district hospitals.
3. Home based palliative care is being provided for chronic, debilitated and progressive cancer patients at 100 districts.
4. Support is being provided for contractual manpower through 1 Medical Oncologist, 1 Cytopathologist, 1 Cytopathology technician, 2 Nurses for day care.
5. 45 centres were to be strengthened as Tertiary Cancer Centres (TCCs) to provide comprehensive cancer care services at a cost of Rs. 6.00 crore each during 2011-12.

Tobacco Control Legislation (49)

A comprehensive tobacco control legislation titled "The Cigarettes and other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act, 2003" was passed by the parliament in April, 2003 and notified in Gazette of India on 25th Feb, 2004. The important provisions of the Act are:

- a. Prohibition of smoking in public places;
- b. Prohibition of direct and indirect advertisement of cigarette and other products;
- c. Prohibition of sale of cigarette and other tobacco products to a person below the age of 18 years;
- d. Prohibition of sale of tobacco products near the educational institutions;
- e. Mandatory depiction of statutory warnings (including pictorial warnings) on tobacco packs; and
- f. Mandatory depiction of tar and nicotine contents alongwith maximum permissible limits on tobacco packs.

The rules related to prohibition of smoking in public places came into force from the 2nd October, 2008. As per rules, it is mandatory to display smoke free signage at all public places. Labelling and packaging rules mandating the depiction of specified health warnings on all tobacco product packs came into force from 31st May, 2009.

National Tobacco Control Programme (3):

In order to facilitate the implementation of the Tobacco Control Laws, to bring about greater awareness about the harmful effects of tobacco, and to fulfill the obligations under the WHO-Framework convention on tobacco control, Govt. of India has launched a new National Tobacco Control Programme in the 11th Five Year Plan. Pilot phase was launched in 16 districts covering 9 states in 2007-08. It now covers 42 districts in 21 states in the country. The main components of the programme are:

1. Public awareness/mass media campaigns for awareness building and for behavioural change;
2. Establishment of tobacco product testing laboratories, to build regulatory capacity, as required under COTPA, 2003;
3. Mainstreaming the programme components as a part of the health delivery mechanism under the NRHM framework;
4. Mainstream research and training on alternate crops and livelihood, with other nodal ministries;
5. Monitoring and evaluation, including surveillance, e.g. adult tobacco survey;
6. Dedicated tobacco control cells for effective implementation and monitoring of anti-tobacco initiatives;
7. Training of health and social workers, NGOs school teachers etc;
8. School programme; and

National Mental Health Programme

The National Mental Health Programme was launched during 1982 with a view to ensure availability of Mental Health Care Services for all, especially the community at risk.
and underprivileged section of the population, to encourage application of mental health knowledge in general health care and social development. A National Advisory Group on mental health was constituted under the Chairmanship of the Secretary, Ministry of Health and Family Welfare for the effective implementation of the National Health Programme. Eleven institutions have been identified for imparting training in basic knowledge and skills in the field of mental health to primary health care physicians and para-medical personnel. At present this programme covers 94 districts.

The aims of the NMHP are: (a) Prevention and treatment of mental and neurological disorders and their associated disabilities; (b) Use of mental health technology to improve general health services; and (c) Application of mental health principles in total national development to improve quality of life (50).

The objectives of the programme are:
1. To ensure availability and accessibility of minimum mental health care for all in the foreseeable future, particularly to the most vulnerable and underprivileged sections of population.
2. To encourage application of mental health knowledge in general health care and in the social development.
3. To promote community participation in the mental health services development, and to stimulate efforts towards self-help in the community.

The programme strategies are:
1. Integration of mental health with primary health care through the NMHP.
2. Provision of tertiary care institutions for treatment of mental disorders.
3. Eradicating stigmatization of mentally ill patients and protecting their rights through regulatory institutions like the Central Mental Health Authority, and State Mental Health Authority.

District Mental Health Programme components are:
(a) Training programmes of all workers in the mental health team at the identified nodal institutes in the state; (b) Public education in mental health to increase awareness and to reduce stigma; (c) For early detection and treatment, the OPD and indoor services are provided; and (d) Providing valuable data and experience at the level of community to the state and centre for future planning, improvement in service and research.

District Mental Health Programme has now incorporated promotive and preventive activities for positive mental health which includes:
- School mental health services: Life skills education in schools, counselling services.
- College counselling services: Through trained teachers' counsellors.
- Work place stress management: Formal & Informal sectors, including farmers, women etc.
- Suicide prevention services: Counselling center at district level, sensitization workshops, IEC, help lines etc.

The National Human Rights Commission also monitors the conditions in the mental hospitals along with the government of India, and the states are acting on the recommendations of the joint studies conducted to ensure quality in delivery of mental care.

Thrust areas (6)
1. District mental health programme in an enlarged and more effective form covering the entire country.
2. Streamlining/modernization of mental hospitals in different parts of the country.
3. Upgrading department of psychiatry in medical colleges and enhancing the psychiatric content of the medical course at the undergraduate as well as postgraduate level.
4. Strengthening the central and state mental health authorities with a permanent secretariat. Appointment of medical officers at state headquarters in order to make the monitoring role more effective.
5. Research and training in the field of community mental health, substance abuse and child adolescent psychiatric clinics.

INTEGRATED DISEASE SURVEILLANCE PROJECT

Integrated disease surveillance project is a decentralized state-based surveillance system in the country. This project is intended to detect early warning signals of impending outbreaks and help initiate an effective response in a timely manner in urban and rural areas. It will also provide essential data to monitor progress of ongoing disease control programme and help allocate health resources more efficiently. The project was launched in Nov. 2004. It is a 5 year project.

The surveillance is needed to recognize cases or clusters of cases to initiate interventions to prevent transmission of disease, to reduce morbidity and mortality, to assess the public health impact of health events or determine and measure trends; demonstrate the need for public health intervention programmes and resources and allocate resources during public health planning; monitor effectiveness of preventive and control measures; identify high-risk groups or geographical areas to target interventions and guide analytic studies; and develop hypothesis that lead to analytic studies about risk factors for disease cessation, propagation and progression (51).

In this project, different types of intervention are proposed. These include: (a) Sharing of surveillance information of disease control programmes; (b) Developing effective partnership with health and non-health sectors in surveillance; (c) including non-communicable and communicable diseases in the surveillance system; (d) Effective partnership of private sector and NGOs in surveillance activities; (e) Bringing academic institutions and medical colleges into the primary public health activity of disease surveillance.

The important information in disease surveillance are - who gets the disease, how many get the disease, where did they get the disease, why did they get the disease and what needs to be done as public health response.

The components of the surveillance activity are:
(a) Collection of data
(b) Compilation of data
(c) Analysis and interpretation
(d) Follow-up action
(e) Feedback.
The prerequisite of the effective surveillance are — use of standard case definition, ensure regularity of reports and the accuracy of reports.

The classification of surveillance in IDSP is as follows:

- **Synthetic diagnosis** — diagnosis is made on the basis of clinical patterns by paramedical personnel and members of the community.
- **Presumptive diagnosis** — diagnosis made on typical history and clinical examination by medical officer.
- **Confirmed diagnosis** — clinical diagnosis by a medical officer and or positive laboratory identification.

**Syndromes under surveillance (51):**

The surveillance health staff will undertake disease surveillance based on broad categories of presentation. The following clinical syndromes will be under surveillance in IDSP:

1. Fever
   - Less than 7 days duration or any localizing signs
   - With rash
   - With altered sensorium or convulsions
   - Bleeding from skin or mucous membrane
   - Fever more than 7 days and or without localizing signs
2. Cough more than 3 weeks duration
3. Acute febrile paralysis
4. Diarrhoea
5. Jaundice
6. Unusual events causing death or hospitalization.

These syndromes are intended to pick up all priority diseases listed under regular surveillance at the level of the community under the Integrated Disease Surveillance Project.

- Fever with or without localizing signs: Malaria, Typhoid, JE, Dengue, Malaria, Yellow Fever, Anthrax, Plague
- Cough more than 3 weeks duration: Tuberculosis
- Acute febrile paralysis: Poliomyelitis
- Diarrhoea: Cholera
- Jaundice: Hepatitis, Leptospirosis, Dengue, Malaria
- Unusual syndromes: Anthrax, Plague

The core conditions under surveillance in IDSP are as follows (52):

- **(i) Regular Surveillance**
  - Vector borne disease: Malaria
  - Water borne disease: Acute diarrhoeal disease (cholera)
  - Respiratory disease: Tuberculosis
  - Vaccine preventable diseases: Measles
  - Diseases under eradication: Polio
  - Other conditions: Road traffic accidents
  - Other international commitments: Plague

- **(ii) Sentinel Surveillance**
  - Sexually transmitted diseases / blood borne diseases: HIV / HBV, HCV
  - Other conditions: Water quality monitoring
  - Outdoor air quality: (Large urban centres)

- **(iii) Regular periodic surveys**
  - NCD risk factors: Anthropometry, Physical activity, Blood pressure, Tobacco, Nutrition etc.

**National Guinea Worm Eradication Programme**

India launched its National Guinea Worm Eradication Programme in 1984 with technical assistance from WHO. From the very beginning the programme was integrated into the national health system at village level. With well defined strategies, an efficient information and evaluation system and intersectoral coordination at all levels and close collaboration with WHO and UNICEF, India was able to significantly reduce the disease in affected areas.

The country has reported zero cases since August 1996. In February 2000, the International Commission for the Certification of Dracunculiasis Eradication recommended that India be certified free of dracunculiasis transmission (52).

The following activities are continuing as per recommendations of International Certification Team.
International Commission for Certification of Dracunculiasis Eradication, Geneva:

a. Health education activities with special emphasis on school children and women in rural areas.

b. Rumour registration and rumour investigation.

c. Maintenance of guinea-worm disease on list of notifiable disease and continuous of surveillance in previously infected areas.

d. Careful supervision of the functioning of hand pumps and other sources of safe drinking water, and provision of additional units, wherever necessary.

YAWS ERADICATION PROGRAMME (5)

The disease has been reported in India from the tribal communities living in hilly forest and difficult to reach areas in 49 districts of 10 states, namely Andhra Pradesh, Assam, Chhattisgarh, Gujarat, Jharkhand, Madhya Pradesh, Maharanastha, Orissa, Tamil Nadu and Uttar Pradesh. National Institute of Communicable Diseases is the nodal agency for planning, guidance, coordination, monitoring and evaluation of the programme. The programme is implemented by the State Health Directorates of Yaws endemic states utilizing existing health care delivery system with the coordination and collaboration of department of tribal welfare and other related institutions.

The number of reported cases has come down from more than 3,500 to Nil during the period from 1996 to 2004, since then no new case has been reported.

NATIONAL PROGRAMME FOR CONTROL AND TREATMENT OF OCCUPATIONAL DISEASES

Government of India launched a scheme called "National Programme for Control and Treatment of Occupational Diseases" in 1998-99. The National Institute of Occupational Health, Ahmedabad (NIOM) has been identified as the nodal agency for this programme.

The following research projects have been proposed by the government (53):

1. Prevention, control and treatment of silicosis and silico-tuberculosis in agate industry.

2. Occupational health problems of tobacco harvesters and their prevention.

3. Hazardous process and chemicals, database generation, documentation, and information dissemination.

4. Capacity building to promote research, education, and training at National Institute of Occupational Disease.

5. Health Risk Assessment and development of intervention programme in cottage industries with high risk of silicosis.

6. Prevention and control of occupational health hazards among salt workers in the remote desert areas of Gujarat and Western Rajasthan.

NUTRITIONAL PROGRAMME

Please refer to chapter 10, for details.

NATIONAL FAMILY WELFARE PROGRAMME

See chapter 8 page 516 for details.

NATIONAL WATER SUPPLY AND SANITATION PROGRAMME

The National Water Supply and Sanitation Programme was initiated in 1954 with the object of providing safe water supply and adequate drainage facilities for the entire urban and rural population of the country. In 1972 a special programme known as the Accelerated Rural Water Supply Programme was started as a supplement to the National water supply and sanitation programme. Inspite of increased financial outlay during the successive Five Year Plans, only a small dent was made on the overall problem. During the Fifth Plan, rural water supply was included in the Minimum Needs Programme of the State Plans. The Central Government is supporting the efforts of the States in identifying problem villages through assistance under Accelerated Rural Water Supply Programme. A "problem village" has been defined as one where no source of safe water is available within a distance of 1.6 km, or where water is available at a depth of more than 15 metres, or where water source has excess salinity, iron, fluorides and other toxic elements, or where water is exposed to the risk of cholera.

The stipulated norm of water supply is 40 litres of safe drinking water per capita per day, and at least one hand pump/spot-source for every 250 persons. Information, education and communication is an integral part of rural sanitation programme to adopt proper environmental sanitation practices including disposal of garbage, refuse and waste water, and to convert all existing dry latrines into low cost sanitary latrines. The priority is to evolve financially viable sewerage systems in big cities and important pilgrimage and tourist centres and recycling of treated effluents for horticulture, irrigation and other non-domestic purposes (54).

The programme was subsequently renamed as the Rajiv Gandhi National Drinking Water Mission in 1991. In 1999-2000, Sector Reform Project was started to involve the community in planning, implementation and management of drinking water schemes which was in 2002 scaled up as the Swajalshala Programme.

Swajalshala (55)

Swajalshala was launched on 25th Dec. 2002. Swajalshala has certain innovative programme principles which need to be adhered to by the state governments and the implementing agencies. Swajalshala is a community-led participatory programme, which aims at making drinking water in rural areas, with full ownership of the community, building awareness among the village community on the management of drinking water projects, including better hygiene practices and encouraging water conservation practices along with rainwater harvesting.

Swajalshala has two components: Swajalshala I (First Dhar) is for a gram panchayat or a group of panchayats (at block / taluk level) and Swajalshala II (Second Dhar) has district as the project area. District water and sanitation mission sanctions swajalshala I. The panchayats and communities have the power to plan, implement, operate, maintain and manage all water supply and sanitation schemes. There is an integrated service delivery mechanism, taking up conservation measures through rain water harvesting and ground water recharge systems for sustained drinking water supply and shifting the role of government from direct service delivery to that of planning, policy
formulation, monitoring and evaluation and partial financial support. On completion of the project, gram panchayat or village will be facilitated to manage the project.

The programme was revised from 1st April 2009 and named as National Rural Drinking Water Programme (56). It is now a component of Bharat Nirman, which focuses on the creation of rural infrastructure.

Bharat Nirman

Bharat Nirman was launched by the Government of India in 2005 as a programme to build rural infrastructure. While phase-I was implemented in the period of 2005-06 to 2008-09, the phase-II was implemented from 2009-10 to 2011-12. At the beginning of phase-I period, priority was given to cover water quality problem and other contaminants, e.g. arsenic and fluoride affected habitations followed by sex, salinity, nitrate.

New initiatives in 12th Five Year Plan

1. In order to raise coverage of piped water supply, toilet coverage and strengthening of institutions and systems in rural drinking water and rural sanitation sectors, the Ministry has proposed a Rural Water Supply and Sanitation Project for low income states;
2. Enhancement of service levels for rural water supply from the norm of 40 lpcd to 55 lpcd for designing of system. The target being at least 50 per cent of rural population in the country to have access to water within their household premises or within 100 metres radius, with at least 30 per cent having individual household connections, as against 13 per cent today (56).

Rural Sanitation Programme (56)

Nirmal Bharat Abhiyan (NBA)

In 2012, a paradigm shift was made in the Total Sanitation Campaign, by launching the Nirmal Bharat Abhiyan, in the 12th Five Year Plan. The objective of NBA is to achieve sustainable behavioural change with provision of sanitary facilities in rural communities in a phased manner, saturation mode with "Nirmal Grams" as outcomes.

Swachh Bharat Abhiyan

Prime Minister Shri Narendra Modi launched country's biggest cleanliness drive on 2nd October 2014. The campaign aims to accomplish a vision of clean India by 2nd October 2019.

MINIMUM NEEDS PROGRAMME

The Minimum Needs Programme (MNP) was introduced in the first year of the Fifth Five Year Plan (1974-78). The objective of the programme is to provide certain basic minimum needs and thereby improve the living standards of the people. It is the expression of the commitment of the government for the "social and economic development of the community particularly the underprivileged and under-served population". The programme includes the following components:

a. Rural Health
b. Rural Water Supply
c. Rural Electrification
d. Elementary Education
e. Adult Education
f. Nutrition
g. Environmental improvement of Urban Slums
h. Houses for landless labourers

There are two basic principles which are to be observed in the implementation of MNP: (a) the facilities under MNP are to be first provided to those areas which are at present underserved so as to remove disparities between different areas; (b) the facilities under MNP should be provided as a package to an area through intersectoral area projects, to have a greater impact.

In the field of rural health, the objectives to be achieved by the end of the Eighth Five Year Plan, under the minimum needs programme were: one PHC for 30,000 population in plain and 20,000 population in hilly areas; one sub-centre for a population of 5,000 people in the plains and for 3000 in trihal and hilly areas; and one community health centre (rural hospital) for a population of one lakh or one C.D. Block by the year 2000. The establishment of PHCs, sub-centres, upliftation of PHCs, and construction of buildings thereof are all included in the State sector of the minimum needs programme.

In the field of nutrition, the objectives are (a) to extend nutrition support to 11 million eligible persons (b) to expand "special nutrition programme" to all the ICDS projects, and (c) to consolidate the mid-day meal programme and link it to health, potable water and sanitation.

20-POINT PROGRAMME

In addition to the Five Year Plans and Programmes, in 1975, the Govt. of India initiated a special activity. This was the 20-Point programme – described as an agenda for national action to promote social Justice and economic growth.

On August 20, 1986, the existing 20-Point Programme was restructured. Its objectives are spelt out by the Government as "eradication of poverty, raising productivity, reducing inequalities, removing social and economic disparities and improving the quality of life".

At least 8 of the 20 points are related, directly or indirectly, to health. These are:

Point 1 – Attack on rural poverty
Point 7 – Improvement of water
Point 8 – Health for all
Point 9 – Two-child norm
Point 10 – Expansion of education
Point 14 – Housing for the people
Point 15 – Improvement of slums
Point 17 – Protection of the environment

The restructured 20-Point Programme constitutes the Charter for the country's socio-economic development. It has been described as "the cutting edge of the plan for the poor".

References
Demography is, as understood today, is the scientific study of human population. It focuses its attention on three readily observable human phenomena: (a) changes in population size (growth or decline) (b) the composition of the population and (c) the distribution of population in space. It deals with five "demographic processes", namely fertility, mortality, marriage, migration and social mobility. These five processes are continuously at work within a population, determining size, composition and distribution.

Community medicine is vitally concerned with population, because health in the group depends upon the dynamic relationship between the numbers of people, the space which they occupy and the skill that they have acquired in providing for their needs. The main sources of demographic statistics in India are population censuses, National Sample Surveys, registration of vital events, and ad hoc demographic studies.

Demographic cycle

The history of world population since 1650 suggests that there is a demographic cycle of 5 stages through which a nation passes:

(1) FIRST STAGE (High stationary)
This stage is characterized by a high birth rate and a high death rate which cancel each other and the population remains stationary. India was in this stage till 1920.

(2) SECOND STAGE (Early expanding)
The death rate begins to decline, while the birth rate remains unchanged. Many countries in South Asia, and Africa are in this phase. Birth rates have increased in some of these countries possibly as a result of improved health conditions, and shortening periods of breast-feeding (1).

(3) THIRD STAGE (Late expanding)
The death rate declines still further, and the birth rate tends to fall. The population continues to grow because births exceed deaths. India has entered this phase. In a number of developing countries (e.g., China, Singapore) birth rates have declined rapidly.

(4) FOURTH STAGE (Low stationary)
This stage is characterized by a low birth and low death rate with the result that the population becomes stationary. zero population growth has already been recorded in Austria during 1960-85. Growth rates as little as 0.1 percent were recorded in UK, Denmark, Sweden and Belgium during 1960-85. In short, most industrialized countries have undergone a demographic transition shifting from a high birth and high death rates to low birth and low death rates.

(5) FIFTH STAGE: (Declining)
The population begins to decline because birth rate is lower than the death rate. Some East European countries, notably Germany and Hungary are experiencing this stage.

WORLD POPULATION TRENDS

At the beginning of the Christian era, nearly 2,000 years ago, world population was estimated to be around 250 million. Subsequent estimates of the world population, and rates of increase are given in Table 1.

It required all the human history up to the year 1800 for the world population to reach one billion. The second billion came in 130 years (around 1930), the third billion in 30 years (around 1960), the fourth billion in 15 years (in 1974), the fifth billion in 12 years (in 1987), and the sixth billion in 12 years (1999). On October 12th 1999 world population became 6 billion. The 7th billion came in 2014 (after 15 years). It’s expected to reach 8 billion by 2025-02.

About three fourths of the world’s population lives in the developing countries. The population of the ten most populous countries of the world and their relative share is shown in Fig. 1. Although, in terms of population USA ranks...
third in the world after India, there is a yawning gap of 978 million between the population of these two countries. The United Nations has estimated that world’s population grew at an annual rate of 1.23 per cent during 2000–2010. China registered a much lower annual growth rate of population (0.6 per cent) during 2002–2012, as compared to India (1.4 per cent). In fact, the growth rate of China is now very much comparable to that of USA (0.9 per cent).

Three countries of SEAR, i.e. India (17.5 per cent), Indonesia (3.49 per cent) and Bangladesh (2.19 per cent) are among the most populous ten countries of the world. At present India’s population is second to that of China. According to UN projections India’s population will reach 1.53 billion by the year 2050, and will be the highest population in the world. The trend of population increase in South East Asia Region countries is as shown in Table 2.

The world’s birth rate fell below 30 for the first time around 1975 and had declined to about 20 during 2012 (5). In most of the world the decline reflected falling birth rates and a global bend towards smaller families. The outstanding examples are Singapore and Thailand. In Singapore, in 40 years, the birth rate fell from 23 per thousand in 1970 to 10 in 2012, and, in Thailand from 37 to 10 during the same period (Table 4).

Source: (5)

In all these countries, key factors in fertility decline included changes in government attitudes towards growth, the spread of education, increased availability of contraception and the extension of service offered through family planning programmes, as well as the marked change in marriage patterns.

Death rates have also declined worldwide over the last decades. The global death rate declined from 1.0 (between 1975–1980) to 0.8 per thousand population during 2012, a reduction of 25 per cent. The decline in the crude death rate of the South-East Asia Region has been more marked, from 16.1 to 7.5 per 1000 population (6).

In countries with a relative young population, crude death rates are mainly affected by infant and child mortality. With improvement in maternal and child health services, successful implementation of the expanded programme on immunization, diarrhoeal disease and acute respiratory
infection control programmes, as well as with control of other infectious diseases, there has been marked reduction in infant and child mortality rates, which are reflected in the declining crude death rates.

**Growth rates**

When the crude death rate is subtracted from the crude birth rate, the net residual is the current annual growth rate, exclusive of migration. The relation between the growth rate and population increase is as shown in Table 5.

Source: (7)

It is said that population growth rates, like railway trains, are subject to momentum. They start slowly and gain momentum. Once in motion, it takes time to bring the momentum under control. As rate of the train the control factors are mass and inertia. In population, they are age distribution, marriage customs and numerous cultural, social and economic factors.

The world population growth rate was at, or near its peak, around 1970, when the human population grew by an estimated 1.92 per cent. The most recent data show a slight decline since then to 1.2 per cent in 2012.

The growth rate is not uniform in the world. There are many countries in the world (e.g., European countries) where the growth rate is less than 0.3 per cent per year. In developing countries, the growth rates are excessive – it is around 2.6 per cent in Africa, 1.1 per cent in Latin America, 0.3 per cent in Europe and industrialized countries, and 1.3 per cent in Asia. A population growing at 0.5 per cent per year will double in about 140 years, a population growing at 3 per cent per year will double is about 20–25 years (Table 5). These differences in growth rates are largely the result of fertility and mortality patterns. The salient features of population growth at a glance are as follows:

- Approximately 95 per cent of this growth is occurring in the developing countries.
- Currently, one-third of the world’s population is under the age of 15, and will soon enter the reproductive bracket, giving more potential for population growth.
- The UNFPA estimates that world population is most likely to reach 10 billion people by 2050, and 20.7 billion a century later.
- The expected number of births per women, at current fertility rates (2012) is for industrialized countries 1.7, developing countries 2.9 and for least developed countries 4.1. The global total fertility rate is 2.5.

The rampant population growth has been viewed as the greatest obstacle to the economic and social advancement of the majority of people in the underdeveloped world.

**DEMOGRAPHIC TRENDS IN INDIA**

**Demographic indicators**

Demographic characteristics provide an overview of its population size, composition, territorial distribution, changes therein and the components of changes such as nativity, mortality and social mobility. Demographic indicators have been divided into two parts – population statistics and vital statistics.

Population statistics include indicators that measure the population size, sex ratio, density and dependency ratio.

Vital statistics include indicators such as birth rate, death rate, natural growth rate, life expectancy at birth, mortality and fertility rates.

These indicators help in identifying areas that need policy and programmed interventions, setting near and far-term goals and deciding priorities, besides understanding them in an integrated structure.

With a population of 1.364 million in the year 2014, India is the second most populous country in the world, next only to China, whereas seventh in land area. With only 2.4 per cent of the world’s land area, India is supporting almost 17.5 per cent of the world’s population. The population of India since 1901, average annual exponential growth rate (%), and the decadal growth of population (%) is as shown in Table 6.

Source: (8)

India’s population has been steadily increasing since 1921. The year 1921 is called the “big divide” because the absolute number of people added to the population during each decade has been on the increase since 1921 (Table 6). India’s population is currently increasing at the rate of 16 million each year.

India’s population numbered 238 million in 1901, doubled in 60 years to 459 million (1961); doubled again, this time in only 30 years to reach 846 million by 1991. It crossed 1 billion mark on 11 May 2000, and is projected to reach 1.53 billion by the year 2050. This will then make India the most populous country in the world, surpassing China.
With the division of some states the rank of most populous states have changed. Table 7 shows the ten most populous states in the country by rank. It is seen that Uttar Pradesh comes first with about 199,581 million people, Maharastra comes second with 122,372 million people and Bihar comes third with 103,804 million people. These three states account for about 71 per cent of the total population of India (8).

Source: (8)

It has been estimated that with current trends, the population in India will increase from 1.210 billion to 1.4 billion during the period 2011 to 2026, an increase of 13.5 per cent in twenty five years at the rate of 1.2 per cent annually. There is a substantial difference in total fertility rate in between and within states. At one end of spectrum are southern states like Kerala, Tamil Nadu, Karnataka and Andhra Pradesh with total fertility rate at or below replacement levels. At the other end are high fertility states like Uttar Pradesh, Chhattisgarh, Uttarakhand, Rajasthan, Jharkhand, Bihar, Madhya Pradesh and Orissa, with an estimated combined total fertility rate of 4.2 in 2000. The estimated year by which some high fertility states will reach replacement level of fertility if current trend continues is as follows (9):

- Uttar Pradesh: 2027
- Madhya Pradesh: 2025
- Chhattisgarh: 2022
- Uttarakhand: 2022
- Bihar: 2021
- Rajasthan: 2021
- Jharkhand: 2018
- India: 2021

It is matter of concern that these states will delay the attainment of replacement level of fertility in India until 2021, with Uttar Pradesh projected to reach this level by 2027. These high fertility states are anticipated to contribute about 30 per cent to the nation-wide increase in population. Demographic outcomes in these states will determine the timing and size of population at which India achieves population stabilization.

### Age and sex composition

The age-sex composition of India's population is as shown in Table 8. In the age group 0–14 years male population is about 1.4 per cent more than female, whereas in the age group 60+, percentage of female population is 0.8 per cent more than male population. The proportion of population in the age group 0–14 years is higher in rural areas (30.5 per cent) than in urban areas (25.2 per cent), for both male and female population (10).

The proportion of population below 14 years of age is showing decline, whereas the proportion of elderly in the country is increasing. This trend is to continue in the time to come. The increase in the elderly population will impose a greater burden on the already overstretched health services in the country.

### Age pyramids

The age structure of a population is best represented as shown in Fig.2.

Such a representation is called an "Age Pyramid". A vivid contrast may be seen in the age distribution of men and women in India and in Switzerland. The age pyramid of India is typical of developing countries, with a broad base and a tapering top. In the developed countries, as in Switzerland, the pyramid generally shows a bulge in the middle, and has a narrower base.

### Sex ratio

Sex ratio is defined as "the number of females per 1000 males". One of the basic demographic characteristics of the population is the sex composition. In any study of population, analysis of the sex composition plays a vital role. The sex composition of the population is affected by the differentials in mortality conditions of males and females, sex selective migration and sex ratio at birth. "Female deficit syndrome" is considered adverse because of social implications. A low sex ratio indicates strong male-child preference and consequent gender inequities, neglect of the girl child resulting in higher mortality at younger age, female infanticide, female foeticide, higher maternal
mortality and male bias in enumeration of population. Easy availability of the sex determination tests and abortion services may also be proving to be catalyst in the process, which may be further stimulated by preconception sex selection facilities.

The trends in the sex ratio in the country from 1901 onwards are as shown in Table 9.

The sex ratio in India has been generally adverse to women, i.e., the number of women per 1,000 men has generally been less than 1,000. Apart from being adverse to women, the sex ratio has also declined over the decades.

**Sex ratio at birth**: The sex ratio at birth can be affected by sex-selectivity at birth. The sex ratio at birth for India for the year 2011 has been estimated at 878. It varies from 871 in rural areas to 891 in urban areas. Among the bigger states, the sex ratio at birth varies from 1,084 in Kerala to 877 in Haryana. In the rural areas, the highest and lowest sex ratio at birth are in the states of Kerala (1077) and Haryana (880) respectively. The sex ratio in urban areas varies from 1,091 in Kerala to 871 in Haryana. Table 10 shows the variations of sex ratio at birth by residence in the bigger states of the country.

Source: (8)
The term "demographic burden" is used to connote the increase in the total dependency ratio during any period of time, mostly caused by increased child age dependency ratio. This is an inevitable consequence of demographic transition, and the country has to face this problem sooner or later (11).

Density of population
One of the important indices of population concentration is the density of population. It is the ratio between (total) population and surface (land) area. This ratio can be calculated for any territorial unit for any point in time, depending on the source of the population data (11). In the Indian census, density is defined as the number of persons, living per square kilometre. The trends of the density in the country from 1901 onwards are as shown in Table 11. For the year 2014 the density or population per sq. km. in India was 394.

Urbanization
By definition, urban population is the number of persons residing in urban localities. The definition of urban locality varies from country to country. In Indian context, the urban areas are the Towns (places with municipal corporation, municipal area committee, town committee, notified area committee or cantonment board); also, all places having 5,000 or more inhabitants, a density of not less than 1,000 persons per square mile or 390 per square kilometre, pronounced urban characteristics and at least three fourths of the adult male population employed in pursuits other than agriculture (11).

The population in India continues to be predominantly rural with agriculture as the main occupation for the majority of the people. As per provisional population totals of Census - 2011, the rural population stands at 833.1 million (68.84 per cent) and urban population at 377.1 million (31.16 per cent), an increase of 3.35 per cent in urban population. In absolute numbers, rural population has increased by 94.47 million and urban population by 92.00 million in the last decade. Uttar Pradesh has the largest rural population of 155.11 million i.e. 18.52 per cent of country's rural population, whereas Maharashtra has the highest urban population of 50.83 million i.e. 13.48 per cent of the country's urban population. Fig. 3 indicates the level of urbanization in the country.
The family size depends upon, numerous factors, viz., duration of marriage, education of the couple, the number of live births and living children, preference of male children, desired family size, etc.

The question of family size is undoubtedly important from the demographic point of view. The family planning program’s campaign is currently based on the theme of a “two-child” family norm, with a view to reach the long-term demographic goal of NRR=1. Family planning involves both decision regarding the “desired family size” and the effective limitation of fertility once that size has been reached.

Table 12 shows the total fertility rates (completed family size) in India and selected countries. The decrease in family size does not appear to be due to any reduction in fertility; rather it appears to be due to the result of deliberate family planning.

**Literacy and education**

In 1948, the Declaration of Human Rights stated that everyone has a right to education. Yet, even today, this right is being denied to millions of children. Education is a crucial element in economic and social development. Without education, development can neither be broad based nor sustained. The benefits that accrue to a country by having a literate population are multidimensional. Spread of literacy is generally associated with modernization, urbanization, industrialization, communication, and commerce. It forms an important input in the overall development of individuals enabling them to comprehend their social, political and cultural environment better, and respond to it appropriately. Higher levels of education and literacy lead to a greater awareness and also contribute to improvement of economic conditions, and is a pre-requisite for acquiring various skills and better use of health care facilities.

It was decided in 1991 to use the term literacy rate for the population relating to seven years age and above. A person is deemed as literate if he or she can read and write with understanding in any language. A person who can merely read but cannot write is not considered literate. The same concept has been continued in census 2001 and 2011 also. The literacy rate taking into account the total population in the denominator has now been termed as “crude literacy rate”, while the literacy rate calculated taking into account the 7 years and above population in the denominator is called the effective literacy rate. The formula for computing crude literacy rate and effective literacy rate are as follows:
TABLE 13

</table>

The national average of literacy rate is misleading as wide variations exist between the states. Table 13 shows the literacy rates in different states in India. The national percentage of literates in the population above 7 years of age is about 74.04 with literate males about 82.14 per cent and females lagging behind with about 65.46 per cent.

Table 13 shows that Kerala continues to occupy the top rank in the country with about 93.91 per cent literates. Mizoram (91.58 per cent), and Ladakh (92.28 per cent) closely follow Kerala. On the other end is Bihar and Arunachal Pradesh with literacy rate of only 68.82 and 66.9 per cent respectively. The states which have literacy rates below the national average are Arunachal Pradesh, Andhra Pradesh, Bihar and Jharkhand, Jammu & Kashmir, Uttar Pradesh, Rajasthan and Odisha etc.

Source: (65)

Government of India has made education compulsory up to the age of 14 years in the country. Though considerable progress has been made in expanding primary education, a major concern is the high drop-out rates in the first few years of schooling (2).

Life expectancy

Life expectancy – or expectation of life – at a given age is the average number of years which a person of that age may expect to live, according to the mortality pattern prevalent in that country. Demographers consider it as one of the best indicators of a country’s level of development and of the overall health status of its population. Life expectancy at birth has continued to increase.
globally over the years. For 1950–1955, the combined life expectancy at birth for both sexes was 46.5 years. Five decades later by 2008, it was 69 years – an increase of 22.5 years. The increase has been more marked in less developed regions of the world than in the developed regions (14).

Most countries in the world exhibit a sex differential in mortality favouring women – females live longer than males as shown in Table 14. Contrary to this biological expectation, the life expectancy of women in Nepal and Maldives is lower than that of men, while in Bangladesh and India it is almost equal.

Trends in life expectancy show that people are living longer, and this have a right to a long life in good health, rather than one of pain and disability. Health policy makers thus need to recognize this changing demographic pattern and plan for prevention and control of diseases associated with old age.

Tables 14 and 15 present life expectancy at birth in India and those in selected countries. Japan leads in life expectancy for both males and females, 80 and 86 years respectively for the year 2014.

**FERTILITY**

By fertility is meant the actual bearing of children. Some demographers prefer to use the word natality in place of fertility. A woman's reproductive period is roughly from 15 to 45 years – a period of 30 years. A woman married at 15 and living till 45 with her husband is exposed to the risk of pregnancy for 30 years, and may give birth to 15 children, but this maximum is rarely achieved.

Fertility depends upon several factors. The higher fertility in India is attributed to universality of marriage, lower age at marriage, low level of literacy, poor level of living, limited use of contraceptives and traditional ways of life. National Family Health Survey-3 conducted in India during 2005–2006 provides some detailed information of fertility trends, as shown in Table 16.

Some of the factors which have engaged attention of demographers since long are discussed below.

1. Age at marriage

The age at which a female marries and enters the reproductive period of life has a great impact on her fertility. The Registrar General of India collected data on fertility on a national scale and found that females who marry before the age of 18 gave birth to a larger number of children than those who married after (18). In India some demographers have estimated that if marriages were postponed from the age of 16 to 20–22, the number of births would decrease by 20–30 per cent (18).
Early marriage is a long-established custom in India. As early as 1929, the Sarada Act was enacted forbidding the practice of child marriage. The census data reveals that prior to 1951, the average age at marriage for girls in India was 13 years. There is, however, a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age at marriage from 15 to 18 years for girls, and from 18 to 21 years for boys. Studies indicate that in many States, the average age at marriage for girls has already moved up to 20 years in 2006, and many others are very close to this. The national average for effective marriage is 21 years. The exceptions are the rural areas, where a substantial proportion of marriages continue to take place when the girl is around 16 years of age (17).

2. Duration of married life

Studies indicate that 10–25 per cent of all births occur within 1–5 years of married life; 50–55 per cent of all births within 5–15 years of married life. Births after 25 years of married life are very few (18). This suggests that family planning efforts should be concentrated in the first few years of married life in order to achieve tangible results.

3. Spacing of children

Studies have shown that when all births are postponed by one year in each age group, there was a decline in total fertility. It follows that spacing of children may have a significant impact on the overall reduction in the fertility rates.

4. Education

There is an inverse association between fertility and educational status. Education provides knowledge, increases exposure to information and media; builds skill for gainful employment; increases female participation in family decision making; and raises the opportunity costs of women's time. The National Family Health Survey-3 shows that the total fertility rate is 1.7 children higher for illiterate women than for women with at least a high school education (Table 16).

5. Economic status

Operational Research studies support the hypothesis that economic status bears an inverse relationship with fertility. The total number of children born declines with an increase in per capita expenditure of the household. The World Population Conference at Bucharest in fact stressed that economic development is the best contraceptive. It will take care of population growth and bring about reductions in fertility.

6. Caste and religion

Muslims have a higher fertility than Hindus. The National Family Health Survey-3 reported a total fertility rate of 3.09 among Muslims as compared to 2.65 among Hindus. The total fertility rate among Christians was found to be 2.35. Among Hindus, the lower castes seem to have a higher fertility rate than the higher castes (17).

7. Nutrition

There appears to be some relationship between nutritional status and fertility levels. Virtually, all weaned societies have low fertility, and poorly fed societies have high fertility. The effect of nutrition on fertility is largely indirect.

8. Family planning

Family planning is another important factor in fertility reduction. In a number of developing countries, family planning has been a key factor in declining fertility (Table 4). Family planning programmes can be initiated readily and require only limited resources, as compared to other factors.

9. Other factors

Fertility is affected by a number of physical, biological, social and cultural factors such as place of women in society, value of children in society, widow remarriage, breast-feeding, customs and beliefs, industrialization and urbanization, better health conditions, housing, opportunities for women and local community involvement. Attention to these factors requires long-term government programmes and vast sums of money.

FERTILITY-RELATED STATISTICS

Fertility may be measured by a number of indicators, as given below. Stillbirths, fetal deaths and abortions, however, are not included in the measurement of fertility in a population (19).

1. Birth Rate

Birth rate is the simplest indicator of fertility, and is defined as "the number of live births per 1000 estimated mid-year population, in a given year". It is given by the formula:

\[ \text{Birth Rate} = \frac{\text{Number of live births during the year}}{\text{Estimated mid-year population}} \times 1000 \]

The birth rate is an unsatisfactory measure of fertility because the total population is not exposed to child bearing. Therefore it does not give a true idea of the fertility of a population.

2. General Fertility Rate (GFR)

It is the "number of live births per 1000 women in the reproductive age-group (15-44 or 49 years) in a given year".

\[ \text{GFR} = \frac{\text{Number of live births in an area during the year}}{\text{Mid-year female population age 15-44 (or 49) in the same area in previous year}} \times 1000 \]

General fertility rate is a better measure of fertility than the crude birth rate because the denominator is restricted to the number of women in the child-bearing age, rather than the whole population. The major weakness of this rate is that not all women in the denominator are exposed to the risk of childbirth.

3. General Marital Fertility Rate (GMFR)

It is the "number of live births per 1000 married women in the reproductive age group (15-44 or 49) in a given year".

\[ \text{GMFR} = \frac{\text{Number of live births in a year}}{\text{Mid-year married female population in the age-group 15-49 years}} \times 1000 \]
4. Age-specific Fertility Rate (ASFR)
A more precise measure of fertility is age-specific fertility rate, defined as the "number of live births in a year to 1000 women in any specified age-group". The age-specific fertility rates throw light on the fertility pattern. They are also sensitive indicators of family planning achievement.

\[
\text{ASFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year female population of the same age group}} \times 1000
\]

5. Age-specific Marital Fertility Rate (ASMFR)
It is the number of live births in a year to 1000 married women in any specified age group.

\[
\text{ASMFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year married female population of the same age group}} \times 1000
\]

6. Total Fertility Rate (TFR)
Total fertility rate represents the average number of children a woman would have if she were to pass through her reproductive years bearing children at the same rates as the women now in each age group (20). It is computed by summing the age-specific fertility rates for all ages; if 5-year age groups are used, the sum of the rates is multiplied by 5. This measure gives the approximate magnitude of "completed family size".

\[
\text{TFR} = 5 \times \sum_{15-19} \text{ASFR} \times 1000
\]

7. Total Marital Fertility Rate (TMFR)
Average number of children that would be born to a married woman if she experiences the current fertility pattern throughout her reproductive span.

\[
\text{TMFR} = 5 \times \sum_{15-19} \text{ASMFR} \times 1000
\]

8. Gross Reproduction Rate (GRR)
Average number of girls that would be born to a woman if she experiences the current fertility pattern throughout her reproductive span (15-44 or 49 years), assuming no mortality.

\[
\text{GRR} = \frac{5 \times \sum_{15} \text{ASFR for female live births}}{1000}
\]

9. Net Reproduction Rate (NRR)
Net Reproduction Rate (NRR) is defined as the number of daughters a newborn girl will bear during her lifetime assuming fixed age-specific fertility and mortality rates (21).

NRR is a demographic indicator. NRR of 1 is equivalent to attaining approximately the 2-child norm. If the NRR is less than 1, then the reproductive performance of the population is said to be below replacement level.

10. Child-woman Ratio
It is the number of children 0-4 years of age per 1000 women of child-bearing age, usually defined as 15-44 or 49 years of age. This ratio is used where birth registration statistics either do not exist or are inadequate. It is estimated through data derived from censuses (8).

11. Pregnancy Rate
It is the ratio of number of pregnancies in a year to married women in the ages 15-44 (or 49) years. The "number of pregnancies" includes all pregnancies, whether these had terminated as live births, stillbirths or abortions or had not yet terminated.

12. Abortion Rate
The annual number of all types of abortions, usually per 1000 women of child-bearing age (usually defined as age 15-44) (22).

13. Abortion Ratio
This is calculated by dividing the number of abortions performed during a particular time period by the number of live births over the same period (23).

14. Marriage Rate
It is the number of marriages in the year per 1000 population:

\[
\text{Marriage} = \frac{\text{Number of marriages in the year}}{\text{Mid-year population}} \times 1000
\]

Demographers consider this a very unsatisfactory rate, because the denominator is comprised primarily of population that is not eligible to marry. A more sensitive rate is the general marriage rate.

\[
\text{General Marriage} = \frac{\text{Number of marriages within one year}}{\text{Number of unmarried persons age}} \times 1000
\]

This rate is more accurate when computed for women than for men because more men than women marry at the older ages (8).

Fertility trends
Researches indicate that the level of fertility in India is beginning to decline. The crude birth rate which was about 49 per thousand population during 1901-11 has declined to about 25.0 per thousand population in 2002, and was 21.6 per thousand population in 2012. The rural urban differential has narrowed. However, the crude birth rate has continued to be higher in rural areas as compared to urban areas in the last 3 decades.

The total fertility rate has declined from 3.6 in 1991 to 2.4 in 2012. The TFR in rural areas has declined from 5.6 in 1973 to 2.6 in 2012, whereas the corresponding decline in urban areas has been from 4.1 to 1.8 during the same period. There are considerable inter-state variations in total fertility rate as shown in Fig. 5. In bigger states it varies from 1.8 in Kerala to 3.3 in Uttar Pradesh and Bihar (19).
Recent estimates of the fertility indicators and age-specific fertility rates in India are given in Table 17.

**Birth and death rates**

The birth and death rates are important components of population growth. The birth and death rates in India are shown in Table 18. A look at Table 18 shows that whereas the death rate has considerably declined from 27.4 in 1951, to an estimated 7.0 per thousand population in 2012, the birth rate has declined markedly from 29.9 in 1951 to an estimated 21.6 per thousand in 2012.

The Fifth Five Year (1974–79) Plan's objective was to reduce the birth rate from 35 per thousand at the beginning of the Plan to 30 per thousand by 1978-79. During 1979–84, the birth rate was stagnating around 33 per thousand with no obvious decline. During 1990, however, the birth rate showed a slight decline, to an estimated 30.2, further declining to 26.4 by the year 1998. The current picture indicates that birth and death rates are both declining in India.

**HIGH BIRTH RATE**: India like other developing countries is faced with the dilemma of a high birth rate and a declining death rate. This is a vicious circle, not easy to break. The causes of high birth rate are:- (1) **Unemployment of man-power**: Marriages are universal and sacramental. Everyone, sooner or later (usually sooner) gets married and participates in reproduction. The individual’s economic security or emotional maturity are seldom a pre-requisite to marriage. (2) **Early marriage**: Marriages are performed early. Data indicate that about 60 per cent of the girls aged 15-19 years are already married. (3) **Early puberty**: Indian girls attain puberty early, between 12 and 14 years. (4) **Low standard of living**: Where standards of living are low, birth rates are high. (5) **Low level of literacy**: The 2011 census showed that only 74.04 per cent of the population was literate. The female literacy is still lower, especially in the rural areas. (6) **Traditional customs and habits**: Customs dictate that every woman must marry and every man must have a son. Children are considered a gift of God and their birth should not be obstructed. (7) **Absence of family planning habit**: Family planning is of recent origin. It has not yet become part of the marital mores of the people. (8) **DECLINING DEATH RATE**: The declining birth rate has been attributed to: (i) absence of natural checks, e.g. famines and large scale epidemics, (2) mass control of diseases, e.g. smallpox, plague, cholera, malaria etc., (3) advances in medical science, e.g. extensive use of
chemotherapeutics, antibiotics, and insecticides, (4) better health facilities, (e.g., establishment of primary health centres and more treatment centres, (5) impact of national health programmes, (6) improvements in food supply, (7) international aid in several directions, and (8) development of social consciousness among the masses.

Demographers opine that further rapid decline in India's death rate may not continue in future. The reason is that most of the "easy" conquest of mortality has been accomplished through the widespread use of vaccines, antibiotics, insecticides, and other life-saving measures. The tasks that remain now are the most difficult ones such as improvements in environmental sanitation and nutrition; and control of non-communicable and genetic diseases.

**Growth rate**

The population growth rates in India are presented in Table 6. Prior to 1921, the population of India grew at a slow rate. This was due to the operation of natural checks (e.g., famines and epidemics) which took a heavy toll of human life. After 1921, the "great divide", the occurrence of famines and epidemics was effectively controlled through better nutrition and improved health care services, with the result that the death rate declined more steeply than the birth rate. Consequently, there was a net gain in births over deaths, leading to rapid growth in population, which rose from 9.6 per cent in 1921 to 1.96 in 1961, 2.20 in 1971, 2.22 in 1981, 2.14 in 1991, 1.93 in 2001 and 1.64 in 2011 (Table 6).

India is now the second most populous country in the world. This nation, in the brief span of 50 years, has added 500 million to its population (147.20 million in 1961 to 1.92 billion in 2011).

The national health goal was to attain a birth rate of 21 and a death rate of 7 per thousand by 2007. This would yield an annual growth rate of 1.2 per cent, which was considered essential for the stabilization of population of India over the next 50 years or so.

**FAMILY PLANNING**

**Definition**

There are several definitions of family planning. An Expert Committee (1971) of the WHO defined family planning as "a way of thinking and living that is adopted voluntarily, upon the basis of knowledge, attitudes and responsible decisions by individuals and couples, in order to promote the health and welfare of the family group and thus contribute effectively to the social development of a country" (29).

Another Expert Committee (1976) defined a more practical family planning as follows: "Family planning refers to practices that help individuals or couples to attain certain objectives.

(a) to avoid unwanted births
(b) to bring about wanted births
(c) to regulate the intervals between pregnancies
(d) to control the time at which births occur in relation to the age of the parents
(e) to determine the number of children in the family.

**Basic human rights**

The United Nations Conference on Human Rights at Tehran in 1968 recognized family planning as a basic human right. The Bucharest Conference (27) on the World Population held in August 1974 endorsed the same view and stated in its \"Plan of Action\" that "all couples and individuals have the basic human right to decide freely and responsibly the number and spacing of their children and to have the information, education, and means to do so.\" The World Conference of the International Women's Year in 1975 also declared \"the right of women to decide freely and responsibly the number and spacing of their children and to have access to the information and means to enable them to exercise that right\" (28). Thus during the past few decades, family planning has emerged from whispers in private quarters to a focus of international concern as a basic human right, and a component of family health and social welfare.

**Scope of family planning services**

Family planning is not synonymous with birth control; it is more than mere birth control. A WHO Expert Committee (1970) has stated that family planning includes in its purview: (1) the proper spacing and limitation of births, (2) advice on sterility, (3) education for parenthood, (4) sex education, (5) screening for pathological conditions related to the reproductive system (e.g., cervical cancer), (6) genetic counselling. (7) premarital consultation and examination, (8) carrying out pregnancy tests, (9) marriage counselling, (10) the preparation of couples for the arrival of their first child, (11) providing services for unmarried mothers, (12) teaching home economics and nutrition, and (13) providing adoption services (29). These activities vary from country to country according to national objectives and policies with regard to family planning. This is the modern concept of family planning.

**Health aspects of family planning** (29, 30, 31)

Family planning and health have a two-way relationship. The principal health outcomes of family planning were listed and discussed by a WHO Scientific Group on the Health Aspects of Family Planning (29). These can be summarized under the following headings:

**Women's health**

(maternal mortality, morbidity of women of childbearing age, nutritional status (weight changes, haemoglobin level), etc.) preventable complications of pregnancy and abortion.

**Foetal health**

(foetal mortality (early and late foetal death); abnormal development.

**Infant and child health**

(neonatal, infant and pre-school mortality, health of the infant at birth (birth weight), vulnerability to diseases.

(a) WOMEN'S HEALTH: Pregnancy can mean serious problems for many women. It may damage the mother's health or even endanger her life. In developing countries, the risk of dying as a result of pregnancy is much greater than in developed countries. The risk increases as the mother grows older and after she has had 3 or 4 children. Family planning by intervening in the reproductive cycle of women, helps them to control the number, interval and timing of pregnancies and births, and thereby reduces maternal mortality and morbidity and improves health. The health impact of family planning occurs primarily through:

(i) the avoidance of unwanted pregnancies; (ii) limiting the number of births and proper spacing; and (iii) timing the...
births, particularly the first and last, in relation to the age of the mother. It is estimated that guaranteeing access to family planning alone could reduce the number of maternal deaths by 25 per cent, and child mortality by 20 per cent (11).

(i) Unwanted pregnancies: The essential aim of family planning is to prevent the unwanted pregnancies. An unwanted pregnancy may lead to an induced abortion.

From the point of view of health, abortion outside the medical setting (criminal abortion) is one of the most dangerous consequence of unwanted pregnancy. Particular mention must be made of the unmarried mother who faces significantly higher health risks. There is also evidence of higher incidence of mental disturbances among mothers who have had unwanted pregnancies.

(ii) Timing of births: Generally mothers face greater risk of dying before the age of 30 and about the age of 30-35. In many countries, complications of pregnancy and delivery show the same pattern of risk, with the highest rate below 20 and over 35 years of age.

(b) Fetal, Infant, Health: A number of congenital anomalies (e.g., Down's syndrome) are associated with advancing maternal age. Such congenital anomalies can be avoided by timing the births in relation to the mother's age. Further, the "quality" of population can be improved only by avoiding completely unwanted births. In the present state of our knowledge, it is very difficult to weigh the overall genetic effects of family planning.

(c) Child Health: Issues relating to family planning are highly relevant to pediatrics. It would seem that family size and birth spacing, if practiced by all, will yield substantial child health benefits. These are: (a) Child mortality: It is well known that child mortality increases when pregnancies occur in rapid succession. A birth interval of 2 to 3 years is considered desirable to reduce child mortality. Family planning is, therefore, an important means of ensuring the survival of all children in a family. (b) Child growth, development and nutrition: Birth spacing and family size are important factors in child growth and development. The child is likely to receive his full share of love and care, including nutrition he needs, when the family size is small and births are properly spaced. Family planning, in other words, is effective prevention against malnutrition.

(c) Infectious diseases: Children living in large-sized families have an increased risk of infection, especially infectious gastroenteritis, respiratory and skin infections.

The welfare concept

Family planning is associated with numerous misconceptions - one of them is its strong association in the minds of people with sterilization. Others relate it with birth control. The recognition of its welfare concept came only a decade and half after its inception, when it was named Family Welfare Programme.

The concept of welfare is very comprehensive and is basically related to quality of life. The Family Welfare Programme aims at achieving a higher end - that is, to improve the quality of life of the people.

Small family norm

Small differences in the family size will make big differences in the birth rate. The difference of only one child per family over a decade will have a tremendous impact on the population.

The objective of the Family Welfare Programme in India is that people should adopt the "small family norm" to stabilize the country's population at the level of some 1,553 million by the year 2050 AD. Symbolized by the inverted red triangle, the programme initially adopted the model of the 3-child family. In the 1970s, the slogan was the famous Do Ye Teen Baai. In view of the seriousness of the situation, the 1980s campaign has advocated the 2-child norm. The current emphasis is on three themes: "Sons or Daughters - two will do"; "Second child after 3 years"; and "Universal Immunisation".

A significant achievement of the Family Welfare Programme in India has been the decline in the fertility rate from 6.4 in the 1950s to 2.4 in 2012. The national target was to achieve a Net Reproduction Rate of '1' by the year 2006, which is equivalent to attaining approximately the 2-child norm. All efforts are being made through mass communication that the concept of small family norm is accepted, adapted and woven into lifestyle of the people.

Eligible couples

An "eligible couple" refers to a currently married couple wherein the wife is in the reproductive age, which is generally assumed to lie between the ages of 15 and 45. There will be at least 150 to 180 such couples per 1000 population in India. These couples are in need of family planning services. About 20 per cent of eligible couples are found in the age group 15-24 years (32). On an average 0.5 million couples are joining the reproductive group every year. The "Eligible Couple Register" is a basic document for organizing family planning work. It is regularly updated by each functionary of the family planning programme for the area falling within his jurisdiction.

The scenario in India as on March, 2010 is as shown in Fig. 6.

![Image of Fig 6 showing total eligible couples, sterilized couples, and couples expected to have higher order of birth (3 & above)]

Source: (24)
Target couples
In order to pin-point the couples who are a priority group within the broad definition of "eligible couples", the term "target couple" was coined. Initially, the target couple was applied to couples who have had 2-3 living children, and family planning was largely directed to such couples. The definition of a target couple has gradually enlarged to include families with one child or even newly married couples (54) with a view to develop acceptance of the idea of family planning from the earliest possible stage. In effect, the term target couple has lost its original meaning. The term eligible couple is now more widely used and has come to stay.

Couple protection rate (CPR)
Couple protection rate (CPR) is an indicator of the prevalence of contraceptive practice in the community. It is defined as the per cent of eligible couples effectively protected against childbirth by one or the other approved methods of family planning, viz. sterilization, IUD, condom or oral pills. Sterilization accounts for over 60 per cent of effectively protected couples (55). Demographers are of the view that the demographic goal of NRR=1 can be achieved only if the CPR exceeds 60 per cent.

CPR protection rate is based on the observation that 50 to 60 per cent of births in a year are of birth order 3 or more. Thus attaining a 60 per cent CPR will be equivalent to cutting off almost all third or higher order births, leaving 2 or less surviving children per couple (33). Therefore, the previous National Population Policy was to attain a CPR of 42 per cent by 1990 (end of Seventh Five Year Plan), and 60 per cent by the year 2000. In short CPR is a dominant factor in the reduction of net reproduction rate.

During 2012-2013, the total number of family planning acceptors by different methods as follows (34A).
- Sterilization......4.57 million
- Vasectomy.........0.12 million
- Tubectomy.........4.45 million
- IUD insertion......5.41 million
- Condom users......13.96 million
- Oral pill users.....6.2 million

However about 60 per cent eligible couples are still unprotected against conception.

During the year 2011, 40 per cent of eligible couples in the reproductive age group 15-44 years were effectively protected against conception by one or the other family planning method.

A state-wise break-up of the figures reported indicates that while some states notably Punjab, Gujarat, Maharashatra, Karnataka, Haryana and Tamil Nadu etc. are forging ahead to cover more than half of their fertility level population by contraception, the other states like Bihar, Uttar Pradesh, Assam, Rajasthan, West Bengal, Jammu and Kashmir etc. are lagging behind with low contraceptive acceptance levels.

NATIONAL POPULATION POLICY 2000
Population policy in general refers to policies intended to decrease the birth rate or growth rate. Statement of goals, objectives and targets are inherent in the population policy. In April 1976 India formed its first - "National Population Policy". It called for an increase in the legal minimum age of marriage from 15 to 18 for females, and from 18 to 21 years for males. However, for the most part, the 1976 statement became irrelevant and the policy was modified in 1977. New policy statement reiterated the importance of the small family norm without compulsion and changed the programme title to "family welfare programme". The National Health Policy approved by the parliament in 1983 had set the long-term demographic goals of achieving a Net Reproductive Rate (NRR) of one by the year 2000 (which was not achieved).

"National Population Policy 2000" is the latest in this series. It reaffirms the commitment of the government towards target free approach in administering family planning services. It gives informed choice to the people to voluntarily avail the reproductive health care services.

The new NPP 2000 is more than just a matter of fertility and mortality rates. It deals with women education; empowering women for improved health and nutrition; child survival and health; the unmet needs for family welfare services; health care for the under-served population groups like urban slums, tribal community, hill area population and displaced and migrant population; adolescent's health and education; increased participation of men in planned parenthood; and collaboration with NGOs.

The objective of NPP 2000 is to bring the TFR to replacement level by 2010. The long term objective is to achieve requirements of sustainable economic growth, social development and environment protection.

The National Socio-Demographic Goals to be achieved by the year 2010 were as follows (56):

1. Address the unmet needs for basic reproductive and child health services, supplies and infrastructure.
2. Make school education up to the age 14 free and compulsory, and reduce drop-outs at primary and secondary school levels to below 20 per cent for both boys and girls.
3. Reduce infant mortality rate to below 30 per 1000 live births.
4. Reduce maternal mortality ratio to below 100 per 100,000 live births.
5. Achieve universal immunization of children against all vaccine preventable diseases.
6. Promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age.
7. Achieve 80 per cent institutional deliveries and 100 per cent deliveries by trained persons.
8. Achieve universal access to information/counselling, and services for fertility regulation and contraception with a wide basket of choices.
9. Achieve 100 per cent registration of births, deaths, marriage and pregnancy.
10. Contain the spread of Acquired Immunodeficiency Syndrome (AIDS), and promote greater integration between the management of reproductive tract infections (RTI) and sexually transmitted infections (STI) and the National AIDS Control Organization.
11. Prevent and control communicable diseases.
12. Integrate Indian Systems of Medicine (ISM) in the provision of reproductive and child health services, and in reaching out to households.
(13) Promote vigorously the small family norm to achieve replacement levels of TFR.
(14) Being about convergence in implementation of related social sector programmes so that family welfare becomes a people centred programme.

If the NPP 2000 was fully implemented, it was anticipated that in the year 2010 the population may be 1107, 210 million. Of 1162 million people, 76 million people will be the Technical Group of Population Projections. However, the provisional population (2110 million) in 2011 is higher by about 160 million over the target set for the year 2010. Efforts at population stabilization will be effective only if an integrated package of essential services is directed at village and household levels. Inadequacies in the existing health infrastructure have led to a net need of 25 per cent of contraceptive services and obvious gap in coverage and outreach. The NPP 2000 is to be largely implemented and managed at panchayat and nagar palika levels in coordination with the concerned state/UT administration.

CONTRACEPTIVE METHODS

(Fertility Regulating Methods)
Contraceptive methods are, by definition, preventive methods to help women avoid unwanted pregnancies. They include all temporary and permanent measures to prevent pregnancy resulting from coitus.

The last few years have witnessed a contraceptive revolution, that is, man trying to interfere with the ovulation cycle.

It is now generally recognized that there can never be an ideal contraceptive – that is, contraceptive that is safe, effective, acceptable, inexpensive, reversible, simple to administer, independent of coitus, long-lasting enough to obviate frequent administration and requiring little or no medical supervision. Further, a method which may be quite suitable for one group may be unsuitable for another because of different cultural patterns, religious beliefs and socio-economic milieu. As there is no single method likely to meet the social, cultural, aesthetic and service needs of all individuals and communities, the search for an "ideal contraceptive" has been given up. The present approach in family planning programmes is to provide a "caterer's choice" that is to offer all methods from which an individual can choose according to his needs and wishes and to promote family planning as a way of life.

The term conventional contraceptives is used to denote those methods that require action at the time of sexual intercourse, e.g., condoms, spermicides, etc. Each contraceptive method has its unique advantages and disadvantages. The success of any contraceptive method depends not only on its effectiveness in preventing pregnancy but on the rate of continuation of its proper use.

The contraceptive methods may be broadly grouped into two classes – spacing methods and terminal methods, as shown below:

1. Spacing methods
   1. Barrier methods
      (a) Physical methods
      (b) Chemical methods
      (c) Combined methods
   2. Intra-uterine devices
   3. Hormonal methods
   4. Post-conceptional methods
   5. Miscellaneous.

II. Terminal methods
   1. Male sterilization
   2. Female sterilization.

BARRIER METHODS

A variety of barrier or "occlusive" methods, suitable for both men and women are available. The aim of these methods is to prevent live sperm from meeting the ovum. Barrier methods have increased in popularity quite recently because of certain contraceptive and non-contraceptive advantages. The main contraceptive advantage is the absence of side-effects associated with the "pill" and IUD. The non-contraceptive advantages include some protection from sexually transmitted diseases, a reduction in the incidence of pelvic inflammatory disease and possibly some protection from the risk of cervical cancer (36). Barrier methods require a high degree of motivation on the part of the user. In general they are less effective than either the pill or the loop. They are only effective if they are used consistently and carefully.

a. PHYSICAL METHODS

1. Condom (37, 38)

   Condom is the most widely known and used barrier device of the males around the world. In India, it is better known by its trade name "NIRODHA", a sanskrit word, meaning prevention. Condom is receiving new attention today as an effective, simple "spaying" method of contraception without side effects. In addition to preventing pregnancy, condom protects both men and women from sexually transmitted diseases.

   The condom is fitted on the erect penis before intercourse. The air must be expelled from the test end to make room for the ejaculate. The condom must be held carefully when withdrawing it from the vagina to avoid spilling seminal fluid into the vagina after intercourse. A new condom should be used for each sexual act.

   Condom prevents the semen from being deposited in the vagina. The effectiveness of a condom may be increased by using it in conjunction with a spermicidal jelly inserted into the vagina before intercourse. The spermicide serves as additional protection in the unlikely event that the condom should slip off or tear.

   Condoms can be a highly effective method of contraception, if they are used correctly at every coitus. Failure rates for the condom vary enormously. Surveys have reported pregnancy rates varying from 2–3 per 100 women-years to more than 24 in typical users (39). Most failures are due to incorrect use.

   The ADVANTAGES of condom are:
   (a) they are easily available
   (b) they are safe
   (c) they are easy to use, do not require medical supervision
   (d) no side effects
   (e) light, compact and disposable, and (f) provides protection not only against pregnancy but also against STD. The

   The
DISADVANTAGES are: (a) it may slip off or tear during coitus due to incorrect use, and (b) it interferes with sex sensation in which some complain while others get used to it. The main limitation of condoms is that many men do not use them regularly or carefully, even when the risk of unwanted pregnancy or sexually transmitted disease is high.

Condoms are manufactured in India by the Hindustan Latex in Trivandrum, London Rubber Industries in Chennai and others. Besides commercial outlets, condoms are supplied under social marketing programme.

Female condom
The female condom is a pouch made of polyurethane, which lines the vagina. An internal ring in the close end of the pouch covers the cervix and an external ring rests outside the vagina. It is prelubricated with silicon, and a spermicide need not be used. It is an effective barrier to STD infection. However, high cost and acceptability are major problems. The failure rates during the first year vary from 5 per 100 women-years pregnancy rate to about 21 in typical users (40).

2. Diaphragm
The diaphragm is a vagi nal barrier. It was invented by a German physician in 1982. Also known as "Dutch cap", the diaphragm is a shallow cup made of synthetic rubber or plastic material. It ranges in diameter from 5–10 cm (2–4 inches). It has a flexible rim made of spring or metal. It is important that a woman be fitted with a diaphragm of the proper size. It is held in position partly by the spring tension and partly by the vaginal muscle tone. This means, for successful use, the vaginal tone must be reasonable. Otherwise, in the case of a severe degree of cystocele, the rim may slip down.

The diaphragm is inserted before sexual intercourse and must remain in place for not less than 6 hours after sexual intercourse. A spermicidal jelly is always used along with the diaphragm. The diaphragm holds the spermicide over the cervix. Side-effects are practically nil. Failure rate by the diaphragm with spermicide vary between 6 to 12 per 100 women-years (39).

ADVANTAGES: The primary advantage of the diaphragm is the almost total absence of risks and medical contraindications. DISADVANTAGES: Initially a physician or other trained person will be needed to demonstrate the technique of inserting the diaphragm into the vagina and to ensure a proper fit. After delivery, it can be used only after involution of the uterus is completed. Practice at insertion, privacy for this to be carried out and facilities for washing and storing the diaphragm precludes its use in most Indian families, particularly in the rural areas. Therefore, the extent of its use has never been great.

If the diaphragm is left in the vagina for an extended period, there is a remote possibility of a toxic shock syndrome, which is a state of peripheral shock requiring resuscitation (41).

Variations of the diaphragm include the cervical cap, vault cap and the vumile cap. These devices are not recommended in the National Family Welfare Programme.

3. Vaginal sponge
Another barrier device employed for hundreds of years is the sponge soaked in vinegar or olive oil, but it is only recently one has been commercially marketed in USA under the name TOCOMATE. It is a small polyeurethane foam sponge measuring 5 cm x 2.5 cm, saturated with the spermicide, hexamethylenetetramine-9. The sponge is far less effective than the diaphragm, but it is better than nothing (42). The failure rate in parous women is between 20 to 40 per 100 women-years and in nulliparous women about 9 to 20 per 100 women-years (40).

b. CHEMICAL METHODS
In the 1960s, before the advent of IUDs and oral contraceptives, spermicides (vaginal chemical contraceptives) were used widely. They comprise four categories (43):

a) Foams: foam tablets, foam aerosols
b) Creams, jellies and pastes – squeezed from a tube
c) Suppositories – inserted manually, and
d) Soluble films – C-film inserted manually.

The spermicides contain a base into which a spermicide is incorporated. The commonly used spermicides are "surface-active agents" which attach themselves to spermatozoa and inhibit oxygen uptake and kill spermatozoa (44).

The main drawbacks of spermicides are: (a) they have a high failure rate (b) they must be used almost immediately before intercourse and repeated before each sex act (c) they must be introduced into those regions of the vagina where sperm are likely to be deposited, and (d) they may cause mild burning or irritation, besides meassiness. The spermicide should be free from potential systemic toxicity. It should not have an inflammatory or carcinogenic effect on the vaginal skin or cervix. No spermicide which is safe to use has yet been found to be really effective in preventing pregnancy when used alone (44). Therefore, spermicides are not recommended by professional advisers. They are best used in conjunction with barrier methods. Recently there has been some concern about possible teratogenic effects on foetuses, following their use. However, this risk is yet to be confirmed (41).

INTRA-UTERINE DEVICES
Types of IUD
There are two basic types of IUD: non-medicated and medicated. Both are usually made of polyethylene or other polymers; in addition, the medicated or bioactive IUDs release either metal ions (copper) or hormones (progestogens).

The non-medicated or inert IUDs are often referred to as first-generation IUDs. The copper IUDs comprise the second and the hormone-releasing IUDs the third generation IUDs. The medicated IUDs were developed to reduce the incidence of side-effects and to increase the contraceptive effectiveness. However, they are more expensive and must be changed after a certain time to maintain their effectiveness (45). Fig. 7 shows different types of IUDs currently in use. In India, under the National Family Welfare Programme, Cu-T-200 B is being used. From the year 2002, Cu-T-380 A has been introduced in the programme (46).
FIRST GENERATION IUDs

The first generation IUDs comprise the inert or non-medicated devices, usually made of polyethylene, or other polymers. They appeared in different shapes and sizes—loops, spirals, coils, rings, and bows. Of all the models, the Lippes Loop is the best known and commonly used device in the developing countries.

Lippes Loop

Lippes Loop is double-S shaped device made of polyethylene, a plastic material that is non-toxic, non-tissue reactive and extremely durable. It contains a small amount of barium sulphate to allow X-ray observation. The Loop has attached threads or "tail" made of fine nylon, which project into the vagina after insertion. The tail can be easily felt and is a reassurance to the user that the Loop is in its place. The tail also makes it easy to remove the Loop when desired.

The Lippes Loop exists in four sizes A, B, C, and D, the latter being the largest. A larger sized device usually has a greater anti-fertility effect and a lower expulsion rate but a higher removal rate because of side-effects such as pain and bleeding. The larger Loops (C and D) are more suitable for multiparous women.

SECOND GENERATION IUDs

It occurred to a number of research workers that the ideal IUD can never be developed simply as a result of obtaining changes in the usual shape or size (42). A new approach was tried in the 1970s by adding copper to the IUD. It was found that metallic copper had a strong anti-fertility effect (47). The addition of copper has made it possible to develop smaller devices which are easier to fit, even in multiparous women. A number of copper bearing devices are now commercially available:

- **Earlier devices**:
  - Copper – 7
  - Copper T-200

- **Newer devices**:
  - Variants of the T device
    1. Cu-T-220 C
    2. Cu-T-380 A or Ag
    3. Nova T
  - Multiload devices
    1. ML-Cu-250
    2. ML-Cu-375

The numbers included in the names of the devices refer to the surface area (in sq. mm) of the copper on the device. Nova T and Cu-T-380 Ag are distinguished by a silver core over which the copper wire is wrapped.

The newer copper devices are significantly more effective in preventing pregnancy than the earlier copper ones or the inert IUDs. The newer copper IUDs—Multiload devices and variants of the T device—offer the further advantage of having an effective life of at least 5 years. They can be left in place safely for the time, unless specific medical or personal reasons call for earlier removal.

Advantages of copper devices
- Low expulsion rate
- Lower incidence of side-effects, e.g., pain and bleeding
- Easier to fit even in multiparous women
- Better tolerated by nulliparas
- Increased contraceptive effectiveness
- Effective as post-coital contraceptives, if inserted within 3–5 days of unprotected intercourse

THIRD GENERATION IUDs

A third generation of IUDs—based on still another principle, i.e., release of a hormone—have become available on a limited scale. The most widely used hormonal device is the progesterone IUD, which is a T-shaped device filled with 38 mg of progesterone, the natural hormone. The hormone is released slowly in the uterus at the rate of 60 mcg daily. It has a direct local effect on the uterine lining, on the cervical mucus and possibly on the sperms. Because the hormone supply is gradually depleted, regular replacement of the device is necessary.

Another hormonal device LNG-20 (Mirena) is a T-shaped IUD releasing 20 mcg of levonorgestrel (a potent synthetic steroid); it has a low pregnancy rate (0.2 per 100 women) and less number of ectopic pregnancies (40). Long-term clinical experience with levonorgestrel releasing IUD has shown to be associated with lower menstrual blood loss and fewer days of bleeding than the copper devices. The levonorgestrel releasing IUD has an effective life of 10 years (40). The hormonal devices would be particularly valuable for women in developing countries in whom excess blood loss caused by insert devices have been shown to result in significant anaemia. But these devices are more expensive, to be introduced on a wide scale.
Mechanism of action of IUDs

At present, the most widely accepted view is that the IUD causes a foreign-body reaction in the uterus causing cellular and biochemical changes in the endometrium and uterine fluids, and it is believed that these changes impair the viability of the sperm and thus reduce its chances of fertilization, rather than its implantation.

Medicated IUDs produce other local effects that may contribute to their contraceptive action. Copper seems to enhance the cellular response in the endometrium (49). It also affects the enzymes in the uterus. By altering the biochemical composition of cervical mucus, copper ions may affect sperm motility, capacitation and survival (49).

Hormone-releasing devices increase the viscosity of the cervical mucus and thereby prevent sperm from entering the cervix. They also maintain high levels of progesterone in the endometrium and thus, relatively low levels of oestrogen, thereby sustaining an endometrium unfavourable to implantation (49).

Effectiveness

The IUD is one of the most effective reversible contraceptive methods. The "theoretical effectiveness" of IUD is less than that of oral and injectable hormonal contraceptives. But since IUDs have longer continuation rates than the hormonal pills or injections, the overall effectiveness of IUDs and oral contraceptives are about the same in family planning programmes (49).

Table 19 shows the rates of pregnancy, expulsion and removal of some of the IUDs. It can be seen from Table 19 that copper devices are more effective than the Lippes Loop in preventing pregnancy, with fewer expulsions. Studies have shown that the effectiveness of copper devices is directly related to the amount of copper surface area (usually this is 200 or 220 sq. mm.).

Change of IUD

Inert IUDs such as Lippes Loop may be left in place as long as required, if there are no side-effects. Copper devices cannot be used indefinitely because copper corrodes and mineral deposits build up on the copper affecting the release of copper ions. They have to be replaced periodically. The same applies to the hormone-releasing devices. This is an inherent disadvantage of medicated devices when they are used in large national family planning programmes.

The Cu-T-380A is approved for use for 10 years. However, the Cu-T-380A has been demonstrated to maintain the efficacy over at least 12 years of use. The Cu-T-200 is approved for 4 years and the Nova T for 5 years. The progesterone-releasing IUD must be replaced every year because the reservoir of progesterone is depleted in 12-18 months. The levonorgestrel IUD can be used for at least 7 years, and probably 10 years. The progestosterone IUD has a slightly higher failure rate, but the levonorgestrel device that releases 15-20 μg levonorgestrel per day is as effective as the new copper IUDs (40).

Advantages

The IUD has many advantages: (a) simplicity, i.e., no complex procedures are involved in insertion; no hospitalization is required; (b) insertion takes only a few minutes; (c) once inserted IUD stays in place as long as required; (d) inexpensive; (e) contraceptive effect is reversible by removal of IUD (f) virtually free of systemic metabolic side-effects associated with hormonal pills (g) highest continuation rate, and (h) there is no need for the continual motivation required to take a pill daily or to use a barrier method consistently. Only a single act of motivation is required. However, as with most contraceptive methods, the IUD can produce side-effects such as heavy menstruation and/or pain.

Contraindications

ABSOLUTE: (a) suspected pregnancy (b) pelvic inflammatory disease (c) vaginal bleeding of undiagnosed aetiology (d) cancer of the cervix, uterus or adenomya and other pelvic tumours (e) previous ectopic pregnancy (50).

RELATIVE: (a) anaemia (b) menorrhagia (c) history of PID since last pregnancy (d) purulent cervical discharge (e) distortions of the uterine cavity due to congenital malformations, fibroids (f) uncontrolled person (45).

The ideal IUD candidate

The Planned Parenthood Federation of America (PPFA) has described the ideal IUD candidate as a woman:

- who has borne at least one child
- who has no history of pelvic disease
- who has normal menstrual periods
- is willing to check out the IUD in the first year
- has access to follow-up and treatment of potential problems
- is in a monogamous relationship.

The federation does not, however, rule out women who may not conform to this profile (51).

An important finding that has swung dramatically is that the IUD is not a method of first choice for nulliparous women. They have more problems with IUDs such as expulsions, low abdominal pain and pelvic infection, than other women. IUDs such as copper-T, which are smaller and more pliable are better suited to the small uterus of the nulliparous women, if they cannot or use alternative methods of contraception.

In 1983, the American College of Obstetricians and Gynaecologists stated that IUDs are "not recommended for women who have not had children or who have multiple partners, because of the risk of PID and possible infertility" (51).

Timing of insertion

Although the loop can be inserted at almost anytime during a woman's reproductive years (except during pregnancy), the most propitious time for loop insertion is...
during menstrual or within 10 days of the beginning of a menstrual period (42). During this period, insertion is technically easy because the diameter of the cervical canal is greater at this time than during the secretory phase. The uterus is relaxed and myometrial contractions which might tend to cause expulsion are at a minimum (44). In addition, the risk that a woman is pregnant is remote at this time.

The IUD insertion can also be taken up during the first week after delivery before the woman leaves the hospital ("immediate postpartum insertion"). Specia care is required with insertions during the first week after delivery because of the greater risk of perforation during this time. Further, the immediate postpartum insertion is associated with a high expulsion rate. A convenient time for loop insertion is 6–8 weeks after delivery ("post-partum insertion"). Postpartum insertion of an IUD has several advantages. It can be combined with the follow-up examination of the women and their child. IUD insertion can also be taken up immediately after a legally induced first trimester abortion. But IUD insertion immediately after a second trimester abortion is not recommended (45). Since there is a risk of infection, most physicians will not approve of an IUD insertion after an illegal abortion (45).

Follow-up

An important aspect of IUD insertion is follow-up which is rarely neglected. The objectives of the follow-up examination are: (a) to provide motivation and emotional support for the woman (b) to confirm the presence of the IUD, and (c) diagnosis and treat any side-effect or complication (53). The IUD wearer should be examined after her first menstrual period, for the chances of loop expulsion are high during this period, and again after the third menstrual period to evaluate the problems of pain and bleeding, and thereafter at six-month or one-year intervals depending upon the facilities and the convenience of the patient.

The IUD wearer should be given the following instructions : (a) she should regularly check the threads or tail to be sure that the IUD is in the uterus; if she fails to locate the threads, she must consult the doctor (b) she should visit the clinic whenever she experiences any side-effects such as fever, pelvic pain and bleeding, and (c) if she misses a period, she must consult the doctor.

SIDE-EFFECTS AND COMPLICATIONS

1. Bleeding

The commonest complaint of women fitted with an IUD (iner or medicated) is increased vaginal bleeding. It accounts for 10–20 per cent of all IUD removals (51). The bleeding may take one of more of the following forms: greater volume of blood loss during menstruation, longer menstrual periods or mid-cycle bleeding (48). From the woman's point of view, irregular bleeding constitutes a source of personal inconvenience; from a medical point of view, the concern is iron-deficiency anaemia. Usually bleeding or spotting between periods settles within 1–2 months (49). The patient who is experiencing the bleeding episodes should receive iron tablets (ferrous sulphate 200 mg, three times daily).

Studies have shown that the greatest blood loss is caused by the larger non-sterilized devices. Copper devices seem to cause less average blood loss. Menstrual blood loss is consistently lower when hormone-releasing devices are used (45).

If the bleeding is heavy or persistent or if the patient develops anaemia despite the iron supplement, the IUD should be removed. Since there is often a direct relationship between the bleeding and the size and configuration of the IUD (50), a change of IUD from the Lippes Loop to one of copper devices is advised. In most women, removal of the device is rapidly followed by a return to the normal menstrual pattern. If an abnormal pattern persists, a full gynaecological examination is required to ensure that there is no pelvic pathology (45).

2. Pain

Pain is the second major side-effect leading to IUD removal. With estimates that 15–40 per cent of IUD removals appear to be for pain only (45). Pain may be experienced during IUD insertion and for a few days thereafter, as well as during menstruation (51). It may manifest itself in low backache, cramps in the lower abdomen and occasionally pain down the thighs. These symptoms usually disappear by the third month (49).

If during insertion, the pain is particularly severe, it is possible that the device may have been incorrectly placed in the uterus or there is a disparity in size between the device and the uterine cavity. Severe pain can also indicate a uterine perforation (45). Pain could also be due to infection. Pain is more commonly observed in nullipara and those who have not had a child for a number of years (52, 53).

Slight pain during insertion can be controlled by analgesics such as aspirin and codeine. If pain is intolerable, the IUD should be removed. In place of a Lippes Loop, a copper device can be tried. If the woman decides not to have an IUD, another method of contraception should be prescribed.

3. Pelvic Infection

Pelvic inflammatory disease (PID) is a collective term that includes acute, subacute and chronic conditions of the ovaries, tubes, uterus, connective tissue and pelvic peritoneum and is usually the result of infection (50). Studies suggest that IUD users are about 2 to 8 times more likely to develop PID that non-contraceptors (54). Risk associated with PID and IUD use is greater among women who use an IUD as a method of birth control (55) and it occurs more in the uterus during IUD insertion. Recent work has focused on PID as being caused by organisms ascending the IUD tail from the lower genital tract to uterus and tubes (56). The organisms include Gardnerella, Anaerobic streptococci, Bacteroides, Clostridium bacilli and Actinomyces. The risk of PID appears to be the highest in the first few months after IUD insertion.

The clinical manifestations of PID are vaginal discharge, pelvic pain and tenderness: abnormal bleeding, chills and fever. In many cases, the infection may be asymptomatic or low grade. Even one or two episodes of PID can cause infertility permanently blocking the fallopian tubes. Therefore, young women should be fully counselled on the risks of PID before choosing an IUD.

When PID is diagnosed, it should be treated promptly with broad-spectrum antibiotics. Most clinicians recommend removing IUD if infection does not respond to antibiotics within 24–48 hours (48). The risk of PID calls for proper selection of cases for IUD insertion, better sterilisation and insertion techniques, and modified devices without tails.
4. Uterine perforation

Many workers have reported uterine perforation by the IUD (57). The reported incidence ranges from 1.5 to 12.900 insertions (57), depending upon the time of insertion, design of the IUD, technique of insertion and operator’s experience. In the hands of trained physicians, it should not be higher than 0.3 per cent (69). The device may migrate into the peritoneal cavity causing serious complications such as intestinal obstruction. Copper devices produce an intense tissue reaction leading to peritoneal adhesions. Perforations occur more frequently when insertions are performed between 48 hours and 6 weeks postpartum. Interestingly, the perforation may be completely asymptomatic and discovered only when searching for a missing IUD. The conclusive diagnosis of perforation is usually made by a pelvic X-ray. Evidence suggests that any IUD that has perforated the uterus should be removed because the risks of intra-abdominal inflammatory response leading to adhesions or perforation of organs within the abdominal cavity outweigh the risks associated with removal (51).

5. Pregnancy

Considering all IUDs together, the actual use failure rate in the first year is approximately 3 per cent (40). It differs, in different types of IUDs. About 50 per cent of uterine pregnancies occurring with the device in situ end in a spontaneous abortion (51). Removal of the IUD in early pregnancy has been found to reduce this abortion rate by half. In women who continue the pregnancy with the device in situ, a 4-fold increase in the occurrence of premature births compared with other women has been reported (45).

The earlier teaching that pregnancy with an IUD in situ is not unsafe is no longer accepted. Pregnancy with an IUD should be regarded as a potential medical complication with the dangers of infection and spontaneous abortion. The options left open are (44):

(a) If the woman requests an induced abortion, this is legally available.

(b) If the woman wishes to continue with the pregnancy and the threads are visible, the device should be removed by gently pulling the threads.

(c) If the woman wishes to continue with the pregnancy and the threads are not visible, there should be careful examination for possible complications. If there are any signs of intrauterine infection and sepsis, evacuation of the uterus under broad-spectrum antibiotic cover is mandatory.

If the woman becomes pregnant with the IUD, she should be advised that only 25 per cent of pregnancies will have a successful outcome if the IUD is left in place.

6. Ectopic pregnancy

The possibility of ectopic pregnancy must be considered when an IUD user becomes pregnant. The ectopic pregnancy rate per 1000 women year in levonorgestrel IUD and Cu-T-380A is about 0.2 as compared to non-contraceptive users, where it is about 3-4.5. With progesteron IUD it is higher—about 6.8, because its action is limited to a local effect on endometrium. With levonorgestrel IUD the chances of ectopic pregnancy are less, because it is associated with a partial suppression of gonadotrophins with subsequent disruption of normal follicular growth and inhibition of ovulation in significant number of cycles (45).

Women using IUDs should be taught to recognize the symptoms of ectopic pregnancy — lower abdominal pain, dark and scanty vaginal bleeding or amenorrhoea. Women at high risk of ectopic pregnancy — because of previous PID, tubal pregnancy or other ectopic pregnancy — should not use an IUD if other methods are feasible (51).

7. Expulsion

Expulsion rates vary between 12-20 per cent (Table 19). Expulsion can be partial or complete. Partial expulsion is diagnosed on speculum examination by observing the stem of the IUD protruding through the cervix. Clinical skill, timing of insertion and the age and parity of the user all influence the likelihood of expulsion.

An expulsion usually occurs during the first few weeks following spontaneous conception or termination. Expulsion is most common among young women, nulliparous women and women who have a postpartum insertion. Expulsion rates are somewhat lower for copper than for inert devices. As many as 20 per cent of all expulsions go undetected. In general, expulsion in itself is not a serious problem, but if expulsion is unnoticed, pregnancy may occur.

8. Fertility after removal

Fertility does not seem to be impaired after removal of a device provided there has been no episode of PID whilst the device was in situ (48). Over 70 per cent of previous IUD users conceive within one year of stopping use (51). It is now established that PID is a threat to woman’s fertility. There is no meaningful data available on the long-term use of IUD on subsequent fertility (45).

9. Cancer and toleration

There is no evidence to date that IUD use increases cancer risks. Nor is there any evidence of developmental abnormality or congenital malformations among the offspring of either former users of IUDs or those who conceive with an IUD in situ (45).

10. Mortality

Mortality associated with IUD use is extremely rare and has been estimated to be one death per 100,000 woman-years of use, the deaths usually following complications such as septic abortion or spontaneous or ectopic pregnancy (45). In fact, IUD is safer than oral contraceptives in this respect, particularly in older or high-risk patients (45).

Of all the available spacing methods of contraception, IUDs are among the most effective, with an average pregnancy rate after one year of about 3–5 per 100 typical users (51). In comparison with other methods, the IUD is a relatively inexpensive form of contraception, because of its long life. Unlike use of barrier methods, IUD use is independent of the time of intercourse. IUDs have a relatively high continuation rates. Inert devices, as well as those with copper lack the systemic metabolic effects associated with oral pills. Women who cannot tolerate the adverse effects of oral pills may find the IUD an acceptable alternative. It does not interfere with lactation. However, because of expulsion and possible side-effects like menstrual irregularities, IUDs should preferably be used in settings where follow-up facilities are available. Evidence to date shows that for a fully informed woman, the IUD can provide a satisfactory, highly effective, relatively low-risk method of contraception.
HORMONAL CONTRACEPTIVES

Hormonal contraceptives when properly used are the most effective spacing methods of contraception. Oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy. They provide the best means of ensuring spacing between one childbirth and another. More than 65 million in the world are estimated to be taking the "pill" of which about 9.52 million are estimated to be in India.

Gonadal steroids

To physicians in general medicine, the term "steroid" refers to adrenal cortical hormones, while to those in gynaecology, it implies gonadal steroids, i.e., oestrogens and progestogens.

a. Synthetic oestrogens: Two synthetic oestrogens are used in oral contraceptives. These are ethinyl oestradiol and mestranol. Both are effective. In fact, mestranol is inactive until converted into ethinyl oestradiol in the liver (59).

b. Synthetic progestogens: These are classified into three groups – progestins, oestrenes and gonanes. (i) Progestins: These include megestrol, clomiphene and medroxy-progesterone acetate. The progestin progestogens are now not recommended in oral contraceptives because of doubts raised by the occurrence of breast tumours in beagle dogs. (ii) Oestrenes: These are also known as 19-norsterosterones, e.g., norethisterone, norgestisterone acetate, lynestrenol, ethynodiol diacetate and norethindrone. These are all metabolized to norethisterone before becoming active. For some women, oestrenes are more acceptable than gonanes. (iii) Gonanes: The most favoured gonane is levonorgestrel (59).

Classification

Hormonal contraceptives currently in use and/or under study may be classified as follows:

A. Oral pills

1. Combined pill
2. Progestogen only pill (POP)
3. Post-coital pill
4. Once-a-month (long-acting) pill
5. Male pill

B. Depot (slow release) formulations

1. Injectables
2. Subcutaneous implants
3. Vaginal rings

A. ORAL PILLS

1. Combined pill

The combined pill is one of the major spacing methods of contraception. The "original pill" which entered into the market in the early 1960s contained 100–200 mcg of a synthetic oestrogen and 10 mg of a progestogen. Since then, a number of improvements have been made to reduce the undesirable side-effects of the pill by reducing the dose of both the oestrogen and progestogen. At the present time, most formulations of the combined pill contain no more than 30–35 mcg of a synthetic oestrogen, and 0.5 to 1.0 mg of a progestogen. The debate continues about the minimum effective dose of the progestogen in the pill which will produce the least metabolic disturbances.

The pill is given orally for 21 consecutive days beginning on the 5th day of the menstrual cycle (for a few preparations 20 or 22 days are advised), followed by a break of 7 days during which period menstruation occurs. When the tablet pack is finished, this cycle is repeated. Another 21 pill packets are taken daily for another cycle. The bleeding which occurs is not like normal menstruation, but is an episode of uterine bleeding from an incompletely formed endometrium caused by the withdrawal of exogenous hormones. Therefore it is called "withdrawal bleeding" rather than menstruation. Further, the loss of blood which occurs is about half that occurring in a woman having ovulatory cycle. If bleeding does not occur, the woman is instructed to start the second cycle one week after the preceding one. Ordinarily, the woman "menstruates" after the second course of pill intake.

The pill should be taken everyday at a fixed time, preferably before going to bed at night. The first course should be started strictly on the 5th day of the menstrual period, as any deviation in this respect may not prevent pregnancy. If the user forgets to take a pill, she should take it as soon as she remembers, and that she should take the next day's pill at the usual time.

Types of pills

The Department of Family Welfare, in the Ministry of Health and Family Welfare, Government of India has made available 2 types of low-dose oral pills under the brand names of MALA-N and MALA-D. It contains Levonorgestrel 0.15 mg and Ethinyl estradiol 0.03 mg. Mala-D is in a package of 28 pills (21 of oral contraceptive pills and 7 brown film coated 60 mg ferrous fumarate tablets) is made available to the consumer under social marketing at a price of Rs. 3 per packet. Mala-N is supplied free of cost through PHCs, urban family welfare centres, etc. Some of the combined pills are as shown in Table 20.

2. Progestogen-only pill (POP)

This pill is commonly referred to as "mini pill" or "micropill". It contains only progestogen, which is given in small doses throughout the cycle. The commonly used progestogens are norethisterone and levonorgestrel.

The progestogen-only pills never gained widespread use because of poor cycle control and an increased pregnancy rate (60). However, they have a definite place in modern-day contraception. They could be prescribed to older women for whom the combined pill is contraindicated because of cardiovascular risks. They may also be considered in young women with risk factors for neoplasia (61) failure. Ovulation hormone level progestogens may lower the high-density lipoproteins may be of some concern.

3. Post-coital contraception

Post-coital (or "morning after") contraception is recommended within 72 hours of an unprotected intercourse. Two methods are available:

- (a) IUD : The simplest technique is to insert an IUD, if acceptable, especially a copper device within 5 days.
- (b) Hormonal : More often a hormonal method may be preferable. In India Levonorgestrel 0.75 mg tablet is approved for emergency contraception. It is used as one tablet of 0.75 mg within 72 hours of unprotected sex and the 2nd tablet after 12 hours of 1st dose.

- Two oral contraceptive pills containing 50 mcg of ethinyl estradiol within 72 hours after intercourse, and the same dose after 12 hours.
- or
- Four oral contraceptive pills containing 30 or 35 mcg of ethinyl estradiol within 72 hours and 4 tablets after 12 hours.
- or
- Mifepristone 10 mg once within 72 hours.

Post-coital contraception is advocated as an emergency method; for example, after unprotected intercourse, rape or contraceptive failure. Opinion is divided about the effect on foetus, should the method fail. Although the failure rate for post-coital contraception is less than 1 per cent, some experts think a woman should not use the hormonal method unless she intends to have an abortion, if the method fails. There is no evidence that foetal abnormalities will occur. But some doubts remain (62).

4. Once-a-month (long-acting) pill

Experiments with once-a-month oral pill in which quinestrol, a long-acting oestrogen is given in combination with a short-acting progestogen, have been disappointing (63). The pregnancy rate is too high to be acceptable. In addition, bleeding tends to be irregular.

5. Male pill

The search for a male contraceptive began in 1950 (64). Research is following 4 main lines of approach:
- (a) preventing spermatogenesis (b) interfering with sperm storage and maturation (c) preventing sperm transport in the vas, and (d) affecting constituents of the seminal fluid. Most of the research is concentrated on interference with spermatogenesis. An ideal male contraceptive would decrease sperm count while leaving testosterone at normal levels. But hormones that suppress sperm production tend to lower testosterone and affect potency and libido.

A male pill made of goosypol - a derivative of cotton-seed oil, has been very much in the news. It is effective in producing azospermia or severe oligospermia, but as many as 10 per cent of men may be permanently azoospermic after taking it for 6 months. Further goosypol could be toxic. Animal studies show a narrow margin between effective and toxic doses. At present it does not seem that goosypol will ever be widely used as a male contraceptive (65).

MODE OF ACTION OF ORAL PILLS

The mechanism of action of the combined oral pill is to prevent the release of the ovum from the ovary. This is achieved by blocking the pituitary secretion of gonadotrophins that is necessary for ovulation to occur. Progestogen-only preparations render the cervical mucus thick and sticky and thereby inhibit sperm penetration. Progestogens also inhibit tubal motility and delay the transport of the sperm and of the ovum to the uterine cavity (63).

EFFECTIVENESS

Taken according to the prescribed regimen, oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy (50). Some women do not take the pill regularly, so the actual rate is lower. In developed countries, the annual pregnancy rate is less than 1 per cent but in many other countries, the pregnancy rate is considerably higher (63).

Under clinical trial conditions, the effectiveness of progestogen-only pills is almost as good as that of the combination products. However, is large family planning programmes, the effectiveness and continuation rates are usually lower than in clinical trials. The effectiveness may also be affected by certain drugs such as rifampicin, phenobarbital and ampicillin (63).

RISKS AND BENEFITS

Historically oral contraceptives were introduced in the early 1960s. During the first decade of their use, investigations focused on the benefit of pregnancy prevention and risk of abnormal cycle bleeding. During the 1970s, following their widespread use it became apparent that the oral contraceptives had some adverse effects, mainly on the oestrogen component of the pill. This led to a reduction of the oestrogen content of the pill until the current 30-35 mcg oral pills were developed. Until 1980, there was little mention of the untoward effects of progestogens.

As we entered the third decade of oral pill use in 1980s, more information about the hazards and benefits of the pill was available from two large British prospective studies – the Royal College of General Practitioners’ study and the Oxford University Family Planning Association’s study, both of which started in 1968 (66, 66, 67). This section summarizes the risks and benefits of the pill as of date.

a. Adverse effects
   i. Cardiovascular effects

Data from the earlier case control studies (68, 69) and the Oral Contraceptive Study of the RCGP (69) and the Oxford
Study in UK (66, 67) provided conclusive evidence that the use of the combined pill was associated with an excess mortality. Women who had used the pill were reported to have a 50 per cent higher death rate than women who had never taken the pill. Virtually, all the excess mortality was due to a single cause, namely myocardial infarction, cerebral thrombosis and venous thrombosis, with or without pulmonary embolus (70, 71). The risk increased substantially with age and cigarette smoking (Table 21). The evidence was convincing that the cardiovascular complications were positively associated with the oestrogen content of the pill.

</tbody>
</table>

The above findings led to the progressive reduction of the oestrogen content to the minimum level necessary to maintain contraceptive effect. Inspite of this reduction, it became clear by 1989 that some of the untoward vascular effects (e.g. hypertension, glucose intolerance) in addition to metabolic effects which are attributed to the progestogen content of the pill. It became clear that progestogen levels must also be minimal to avoid the complications of pill use.

2. Carcinogenesis

A review prepared by WHO (73) concluded that there was no clear evidence of a relationship, either positive or negative between the use of combined pill and the risk of any form of cancer. However, the WHO Multicentre case-control study on the possible association between the use of hormonal contraceptives and breast cancer indicated a trend towards increased risk of cervical cancer with increasing duration of use of oral contraceptives; this finding is being further explored (74).

3. Metabolic effects

A great deal of attention has been focused recently on the metabolic effects induced by oral contraceptives. These have included the elevation of blood pressure, the alteration in serum lipids with a particular effect on decreasing high-density lipoproteins, blood clotting and the ability to modify carbohydrate metabolism with the resultant elevations of blood glucose and plasma insulin (75). These effects are positively related to the dose of the progestogen component (76). Family planning specialists have voiced a growing concern that the adverse effects associated with oral contraceptives could be a potential long-range problem for the users in that they may accelerate atherogenesis and result in clinical problems such as myocardial infarction and stroke.

4. Other adverse effects

(i) Liver disorders: The use of the pill may lead to hepatocellular adenoma and gall bladder disease. Cholestatic jaundice can occur in some pill users. (ii) Lastazine: Preparations containing a relatively high amount of oestrogen adversely affect the quantity and constituents of breast milk (74), and less frequently cause premature cessation of lactation. In a WHO study (74) users of the combined pill experienced a 42 per cent decline in milk volume after 18 weeks, compared with a decline of 12 per cent for users of progestogen-only minipills and 0.16 per cent for controls using non-hormonal preparations. Women taking oral contraceptives, no matter what type, increase small quantities of hormones in their breast milk, but little is known about the long-term impact, if any, on the child (71). (iii) Subsequent fertility: In general, oral contraceptive use worries to be followed by a slight delay in conception (77). The proportion of women becoming pregnant within 2 months of discontinuing the pill may range from 15-35 per cent (78). It is not known whether the prolonged use of the pill beyond 5-10 years affects subsequent fertility. (iv) Ectopic pregnancies: These are more likely to occur in women taking progestogen-only pills, but not in those taking combined pills. (v) Fetal development: Several reports have suggested that oral pills taken inadvertently during (or even just before) pregnancy might increase the incidence of birth defects of the foetus, but this is not yet substantiated (79).

5. Common unwanted effects

(i) Breast tenderness: Breast tenderness, fullness and discomfort have been observed in women taking oral pills. Breast engorgement and fullness are said to be dependent on progestogen; pain and tenderness are attributed to oestrogen. (ii) Weight gain: About 25 per cent of users complain of weight gain. It is usually less than 2 kg, and occurs during the first 6 months of use. This is attributed to water retention, in which case restriction of salt intake is usually effective. (iii) Headache and migraine: Migraine may be aggravated or triggered by the pill. Women, whose migraine requires treatment with vasodilators such as ergotamine, should not take oral pills. (iv) Bleeding disturbances: A small minority of women using oral contraceptives may complain of break-through bleeding or spotting in the early cycles. A few women may not have a withdrawal bleeding at the end of a cycle. Women should be forewarned of these possibilities.

6. Beneficial effects

The single most significant benefit of the pill is its almost 100 per cent effectiveness in preventing pregnancy and thereby removing anxiety about the risk of unplanned pregnancy. Apart from this, the pill has a number of non-contraceptive health benefits (80). Both the Royal College of General Practitioners and the Oxford Family Planning Association's long-term prospective studies of pill use in Britain have shown that using the pill may give protection against at least 6 diseases: benign breast disorders including fibrocystic disease and fibroadenoma, ovarian cysts, iron-deficiency anaemia, pelvic inflammatory disease, ectopic pregnancy and ovarian cancer.
HORMONAL CONTRACEPTIVES

Contraindications
(a) Absolute: Cancer of the breast and genital; liver disease; previous or present history of thromboembolism; cardiac abnormalities; congenital hypothyroidism; undiagnosed abnormal uterine bleeding.
(b) Special problems requiring medical surveillance: Age over 40 years; smoking and age over 35 years; mild hypertension; chronic renal disease; epilepsy; migraine; nursing mothers in the first 6 months; diabetes mellitus; gall bladder disease; history of infrequent bleeding, amenorrhoea, etc. (63).

Duration of use
The pill should be used primarily for spacing pregnancies in younger women. Those over 36 years should go in for other forms of contraception. Beyond 40 years of age, the pill is not to be prescribed or continued because of the sharp increase in the risk of cardiovascular complications (63).

Medical supervision (51)
Women taking oral contraceptives should be advised annual medical examinations. An examination before prescribing oral pills is required (a) to identify those with contraindications, and (b) those with special problems that require medical intervention or supervision. A check-list (Table 22) has been developed for screening women who can be given oral pills by the health workers.

B. DEPOT FORMULATIONS
The need for depot formulations which are highly effective, reversible, long-acting and oestrogen-free for spacing pregnancies in which a single administration suffices for several months or years cannot be stressed. The injectable contraceptives, subdermal implants and vaginal rings come in this category.

1. Injectable contraceptives
There are two types of injectable contraceptives, depot-progestogen and the newer once-a-month combined injectables. The formulation and injection schedules of injectable contraceptives are as shown in Table 23.

A. PROGESTOGEN-ONLY INJECTABLES
Thus far, only two injectable hormonal contraceptives - both based on progestogen - have been found suitable. They offer more reliable protection against unwanted pregnancies than the older barrier techniques. These are:

a. DMPA (Depot-medroxyprogesterone acetate)

b. NET-EN (Norethisterone enantate)
c. DMPA-SC

a. DMPA (82)
Depot-medroxyprogesterone acetate (DMPA or Depo-provera) has been in use since 1960s. The standard dose is an intramuscular injection of 150 mg every 3 months. It gives protection from pregnancy in 99 per cent of women for at least 3 months. It exerts its contraceptive effect primarily by suppression of ovulation. However, it also has an indirect effect on the endometrium and direct action on the fallopian tubes and on the production of cervical mucus, all of which may play a role in reducing fertility. DMPA has been found to be a safe, effective and acceptable contraceptive which requires a minimum of motivation or none at all. Another advantage is that it does not affect lactation. Therefore in the experience of several countries, DMPA has proved acceptable during the postpartum period as a means of spacing pregnancies. However, the side-effects of DMPA viz. weight increase, irregular menstrual bleeding and prolonged infertility after its use are disadvantages limiting the age groups for which the drug could regularly be used. As now practiced in a number of countries, this contraceptive should find good use among multiparae of age over 35 years who have already completed their families.

b. NET-EN
Norethisterone enantate (NET-EN) has been in use as a contraceptive since 1966. However, it has been less extensively used than DMPA. It is given intramuscularly in a dose of 200 mg every 60 days. Contraceptive action appears to include inhibition of ovulation, and progestogen effects on cervical mucus. A slightly higher (0.4) pregnancy rate (failure rate) has been reported as compared to DMPA.

Administration
The initial injection of both DMPA and NET-EN should be given during the first 5 days of the menstrual period. This timing is very important to rule out the possibility of pregnancy. Both are given by deep intramuscular injection into the gluteus maximus. The injection site should never be massaged following injections. (83). Although compliance

1 Also called monthly injectables.
2 The U.S. Food and Drug Administration approved Lunelle, but it is currently not available in the United States.

Source: (82)

with regular injection intervals should be encouraged, both DMPA and NET-EN may be given two weeks early or two weeks late (82).

c. DMPA-SC 104 mg (82)

A new lower-dose formulation of DMPA, depo-subQ provera 104 (also called DMPA-SC), is injected under the skin rather than in the muscle. It contains 104 mg of DMPA rather than the 150 mg in the intramuscular formulation. Like the intramuscular formulation, DMPA-SC is given at 3-month intervals.

DMPA-SC is just as effective as the formulation injected into the muscle, and the patterns of bleeding changes and amount of weight gain are similar.

Injections of DMPA-SC are given in the upper thigh or abdomen. DMPA-SC should not be injected intramuscularly, and the intramuscular formulation should not be injected subcutaneously. The intramuscular formulation cannot be diluted to make the lower-dose subcutaneous formulation.

Side-effects

Both DMPA and NET-EN have similar side effects, the most common being disruption of the normal menstrual cycle, manifested by episodes of unpredictable bleeding; at times prolonged and at other times excessive. In addition, many women using DMPA or NET-EN may become amenorrheic. The unpredictable bleeding may be very inconvenient to the user; and amenorrhoea can be alarming, causing anxiety. Studies showed that women discontinuing DMPA became pregnant some 5.5 months (average) after the treatment period. At 2 years, more than 90 per cent of previous users became pregnant (83). A study is in progress in India to examine the return of fertility among women who discontinued NET-EN. The potential long-term effects of DMPA and NET-EN are not yet known.

Contraindications

These include cancer of the breast; all genital cancers; undiagnosed abnormal uterine bleeding; and a suspected malignancy. Women usually should not start using a progestin-only injectable if they have high blood pressure (systolic ≥ 160 mm Hg or diastolic ≥ 100), certain conditions of the heart, blood vessels, or liver including history of stroke or heart attack and current deep vein thrombosis. Also, a woman breast-feeding a baby less than 6 weeks old should not use progestin-only injectables (82).

The particular advantage of DMPA and NET-EN is that they are highly effective, long-lasting and reversible contraceptives. Check-lists have been developed for auxiliaries primarily for the screening of women who can be given injectable contraceptives without being examined by the physician; they can also be utilized in follow-up visits.

B. COMBINED INJECTABLE CONTRACEPTIVES

These injectables contain a progestogen and an oestrogen. They are given at monthly intervals, plus or minus three days. Combined injectable contraceptives act mainly by suppression of ovulation. The cervical mucus is affected, mainly by progestogen, and becomes an obstacle to sperm penetration. Changes are also produced in the endometrium which makes it unfavourable for implantation if fertilization occurs, which is extremely unlikely.

In clinical trials, Cydol/Cydolprovera and Mesigyna have both been found to be highly effective with 12 month failure rates of 0.2 per cent or less for Cydolom/Cyadloprovera and 0.4 per cent for Mesigyna. The side-effects are similar to progestogen only injectables, but are much less. Data on return to ovulation and fertility are limited.

The contraindications are confirmed or suspected pregnancy; past or present evidence of thromboembolic disorders; central nervous or coronary artery disease; focal migraine; malignancy of the breast; and diabetes with
vascular complications. Combined injectables are not suitable for women who are fully breast feeding until 6 months postpartum. It is less suitable for women with risk factors for oestrogen.

2. Subdermal implants

The Population Council, New York has developed a subdermal implant known as Norplant for long-term contraception. It consists of 6 silastic (silicone rubber) capsules containing 52 mg (each) of levonorgestrel (85). More recent devices comprise fabrication of levonorgestrel into 2 small rods, Norplant (R)-2, which are comparatively easier to insert and remove. The silastic capsules or rods are implanted beneath the skin of the forearm or upper arm. Effective contraception is provided for over 5 years. The contraceptive effect of Norplant is reversible on removal of capsules. A large multicentre trial conducted by International Committee for Contraception Research (ICCR) reported a 3-year pregnancy rate of 0.7. The main disadvantages, however, appear to be irregularities of menstrual bleeding and surgical procedures necessary to insert and remove implants.

3. Vaginal rings

Vaginal rings containing levonorgestrel have been found to be effective. The hormone is slowly absorbed through the vaginal mucosa, permitting most of it to bypass the digestive system and liver, and allowing a potentially lower dose. The ring is worn in the vagina for 3 weeks of the cycle and removed for the fourth week (86).

POST-CONCEPTIONAL METHODS

Termination of pregnancy

Menstrual regulation

A relatively simple method of birth control is "menstrual regulation." It consists of aspiration of the uterine contents 6 to 14 days of a missed period, but before most pregnancy tests can accurately determine whether or not a woman is pregnant (44). Cervical dilation is indicated only in nulliparas or in apprehensive subjects. No after-care is necessary as a rule.

The immediate complications are uterine perforation and trauma. Late complications (after 6 weeks) include a tendency to abortion or premature labour, infertility, menstrual disorders, increase in ectopic pregnancies and Rh-immunization (87).

Some regard menstrual regulation as very early abortion, others view it as a treatment for delayed periods. Menstrual regulation differs from abortion in 3 respects (88): (a) the lack of certainty if a pregnancy is being terminated. Microscopic examination of the aspirated material can confirm pregnancy post fact, but it is not obligatory (b) the lack of legal restrictions, and (c) the increased safety of the early procedure.

Menstrual induction

This is based on disturbing the normal progesterone-progesterin balance by intrauterine application of 1.5 mg solution (or 2.5–5 mg pellet) of progesterin P2. Within a few minutes of the progesterin impact, performed under sedation, the uterus responds with a sustained contraction lasting about 7 minutes, followed by cyclic contractions continuing for 3–4 hours. The bleeding starts and continues for 7–8 days (87).

Oral abortifacient

Mifepristone (RU 486) in combination with misoprostol is 95 per cent successful in terminating pregnancies of up to 9 weeks' duration with minimum complications. The commonly used regimen is mifepristone 200 mg orally on day 1, followed by misoprostol 800 mcg vaginally either immediately or within 6–8 hours. Commercially it comes as an MTP kit having combination tablets of mifepristone 200 mg one tablet and misoprostol 200 mcg 4 tablets (800 mcg).

The other regimen is a dose of mifepristone 600 mg on day one, followed by 400 mcg orally of misoprostol on day three.

The patient should return for a follow-up visit approximately 14 days after the administration of mifepristone to confirm by clinical examination or ultrasonographic scan that a complete termination of pregnancy has occurred. Patients who have an ongoing pregnancy at this visit have a risk of fetal malformation resulting from the treatment. Surgical termination is recommended to manage medical abortion treatment failures.

Contraindications

Administration of mifepristone and misoprostol is contraindicated in following conditions: (1) History of allergy or known hypersensitivity to mifepristone, misoprostol or other progestins; (2) Confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass; (3) IUD in place; (4) Chronic adrenal failure; (5) Haemorrhagic disorder or concurrent anticoagulant therapy; (6) Inherited porphyria; and (7) If a patient does not have adequate access to medical facilities equipped to provide emergency treatment of incomplete abortion and blood transfusion.

ABORTION

Abortion is theoretically defined as termination of pregnancy before the foetus becomes viable (capable of living independently). This has been fixed administratively at 28 weeks, when the foetus weighs approximately 1000 g. Abortion is sought by women for a variety of reasons including birth control. In fact, in some countries (e.g., Hungary), the legal abortions exceed live births.

Abortions are usually categorized as spontaneous and induced. Spontaneous abortions occur in every 15 pregnancies (89). They may be considered "Nature's method of birth control". Induced abortions, on the other hand, are deliberately induced - they may be legal or illegal. Illegal abortions are hazardous; they are usually the last resort of women determined to end their pregnancies at the risk of their own lives.

Abortion hazards

It is estimated that of the 210 million pregnancies that occur each year, about 80 million are unintended. In 2008, 21.6 million unsafe abortions were estimated to have occurred, causing about 47,000 deaths. Almost 14 unsafe abortion per 1000 women aged 15–44 years takes place. In developing countries the rate is 16 per 1000 women and least developed countries about 27 per 1000 women in age group 15–44 years. The high unsafe abortion rate exists in parallel to low overall contraceptive use (90).

In India, an ICMR study documented that the rates of safe (legal) and unsafe (illegal) abortion were 6.1 and 13.5 per...
1000 pregnancies respectively. It is evident that perhaps two thirds of all abortions take place outside authorised health facilities and are often performed by untrained people. The

THE EARLY COMPLICATIONS of abortion include haemorrhage, shock, sepsis, uterine perforation, cervical injury, thromboembolism and anaesthetic complications. The LATE SEQUELAE include infertility, ectopic gestation, increased risk of spontaneous abortion and reduced birth weight.

Data indicates that the seventh and eighth week of gestation is the optimal time for termination of pregnancy (92). Studies indicate that the risk of death is 7 times higher for women who wait until the second trimester to terminate pregnancy. The Indian Law (MTP Act, 1971) allows abortion only up to 20 weeks of pregnancy.

Legalization of abortion

During the last 25 years there have been gradual liberalization of abortion laws throughout the world. Until 1971, abortions in India were governed exclusively by the Indian Penal Code 1860 and the Code of Criminal Procedure 1898, and were considered a crime except when performed to save the life of a pregnant woman. The Medical Termination of Pregnancy Act was passed by the Indian Parliament in 1971 and came into force from April 1, 1972 (except in Jammu and Kashmir, where it came into effect from November 1, 1976). Implementing rules and regulations initially written in 1971 were revised again in 1992 (95). The Medical Termination of Pregnancy Act is a health care measure which helps to reduce maternal mortality and morbidity resulting from illegal abortions. It also affords an opportunity for motivating such women to adopt some form of contraception.

THE MEDICAL TERMINATION OF PREGNANCY ACT 1971

The Medical Termination of Pregnancy Act, 1971 lays down:

1. The conditions under which a pregnancy can be terminated.
2. The person or persons who can perform such terminations, and
3. The place where such terminations can be performed.

1. The conditions under which a pregnancy can be terminated under the MTP Act 1971:

There are 5 conditions that have been identified in the Act:

a. Medical – where continuation of the pregnancy might endanger the mother’s life or cause grave injury to her physical or mental health.
b. Eugenic – where there is substantial risk of the child being born with serious handicaps due to physical or mental abnormalities.
c. Humanitarian – where pregnancy is the result of rape.
d. Socio-economic – where actual or reasonably foreseeable environments (whether social or economic) could lead to risk of injury to the health of the mother, and
e. Failure of contraceptive devices – The woman, who has been advised by an unwanted pregnancy resulting from a failure of any contraceptive device or method can be presumed to constitute a grave mental injury to the health of the mother. This condition is a unique feature of the Indian law and virtually allows abortion on request, in view of the difficulty of proving that a pregnancy was not caused by failure of contraception.

The written consent of the guardian is necessary before performing abortion in women under 18 years of age, and in lunatics even if they are older than 18 years.

2. The person or persons who can perform abortion

The Act provides safeguards to the mother by authorizing only a Registered Medical Practitioner having experience in gynaecology and obstetrics to perform abortion where the length of pregnancy does not exceed 12 weeks. However, where the pregnancy exceeds 12 weeks and is not more than 20 weeks, the opinion of two Registered Medical Practitioners is necessary to terminate the pregnancy.

3. Where abortion can be done

The Act stipulates that no termination of pregnancy shall be made at any place other than a hospital established or maintained by Government or a place approved for the purpose of this Act by Government.

Abortion services are provided in hospitals in strict confidence. The name of the abortion seeker is kept confidential, since abortion has been treated statutorily as a personal matter.

MTP RULES (1975)

Rules and Regulations framed initially were altered in October 1975 to eliminate time-consuming procedures involved in MTP and to make services more readily available. These changes have occurred in 3 administrative areas (93, 94).

1. Approval by Board

Under the new rules, the Chief Medical Officer of the district is empowered to certify that a doctor has the necessary training in gynaecology and obstetrics to do abortions. The procedure of doctors applying to Certification Boards was removed.

2. Qualification required to do abortion

The new rules allow for registered medical practitioners to qualify through on the spot training.

"If he has assisted a RMP in the performance of 25 cases of medical termination of pregnancy in an approved institution"

The doctor may also qualify to do MTPs under the new rules if he has one or more of the following qualifications which are similar to the old rules:

(a) 6 months’ housemanship in obstetrics and gynaecology,
(b) a postgraduate qualification in OB/G.
(c) 3 years of practice in OB/G for those doctors registered before the 1971 MTP Act was passed.
(d) 1 year of practice in OB/G for those doctors registered on or after the date of commencement of the Act.

3. The place where abortion is performed

Under the new rules, non-governmental institutions may also take up abortions provided they obtain a licence from the Chief Medical Officer of the district, thus eliminating the requirement of private clinics obtaining a Board licence.
Impact of liberalisation of abortion

Although abortion has been greatly liberalized, the annual number of legal abortions are about 6.1 per 1000 pregnancies, whereas the illegal abortions performed in the country are about 13.5 per 1000 pregnancies. In other words, illegal abortions are still the although it is now more than 40 years since MTP Act was promulgated.

An amendment to the MTP Act in the year 2003 includes decentralization of power for approval of places as MTP centres, from state to district level with the aim of enlarging the network of safe MTP centres, and MTP service providers. The strategy at the community level is: (a) spread awareness regarding safe MTP in the community and the availability of services thereof; (b) Enhance access to confidential counselling for safe MPT; train ANMs, AWWs, and ASHAs to provide such counselling; and (c) Promote post-abortion care through ANMs, AWWs, link workers/ASHAs while maintaining confidentiality. At the facility level the strategy is: (1) To provide manual Vacuum Aspiration facility at all CHCs and at least 50 per cent of PHCs that are being strengthened for 24 hour deliveries; (2) Provide comprehensive and high quality MTP services at all FRUs; and (3) Encourage private and NGO sectors to establish quality MTP services (96).

Repeated abortion is not conducive to the health of the mother. It has to be ensured that abortion does not replace the traditional methods of birth control. The numerous abortion hazards which are inherent should serve as a warning that abortions under the best of circumstances can never be as safe as efficient contraception.

MISCELLANEOUS

1. Abstinence

The only method of birth control which is completely effective is complete sexual abstinence. It is sound in theory; in practice, an oversimplification. It amounts to repression of a natural force and is liable to manifest itself in other directions such as temperamental changes and even nervous breakdown. Therefore, it can hardly be considered as a method of contraception to be advocated to the masses.

2. Coitus interruptus

This is the oldest method of voluntary fertility control. It involves no cost or appliances. It continues to be a widely practised method. The rule withdrawn before ejaculation, and thereby tries to prevent deposition of semen into the vagina. Some couples are able to practise this method successfully, while others find it difficult to manage. The chief drawback of this method is that the sexual nature secreted by the male contains sperm, and even a drop of semen is sufficient to cause pregnancy. Further, the slightest mistake in timing the withdrawal may lead to the deposition of a certain amount of semen. Therefore, the failure rate with this method may be as high as 25 per cent.

Hibbert, the alleged side-effects (e.g., pelvic congestion, vaginitis, anxiety neurosis) were highly magnified. Today, expert opinion is changing in this respect. If the couple prefers it, there should be no objection to its use. It is better than using any family planning method at all. It is conceded that coitus interrupts along with abstinence and abortion played a major role in reducing birth rates in the developed world during the 18th and 19th centuries (44).

3. Safe period (rhythm method)

This is also known as the "calendar method" first described by Ogino in 1936. The method is based on the fact that ovulation occurs from 12 to 16 days before the onset of menstruation (see Fig. 8). The days on which conception is likely to occur are calculated as follows:

![Figure 8: Safe period in a 28-day cycle](image)

The shortest cycle minus 18 days gives the first day of the fertile period. The longest cycle minus 10 days gives the last day of the fertile period. For example, if a woman's menstrual cycle varies from 26 to 31 days, the fertile period during which she should not have intercourse would be from the 8th day to the 21st day of the menstrual cycle, counting day one as the first day of the menstrual period. Fig. 8 shows the fertile period and the safe period in a 28-day cycle.

However, where such calculations are not possible, the couple can be advised to avoid intercourse from the 8th to the 22nd day of the menstrual cycle, counting from the first day of the menstrual period (95).

The drawbacks of the calendar method are: (a) a woman's menstrual cycles are not always regular. If the cycles are irregular, it is difficult to predict the safe period (b) it is only possible for this method to be used by educated and responsible couples with a high degree of motivation and cooperation (c) compulsory abstinence of sexual intercourse for nearly one half of every month—which may be called "programmed sex" (d) this method is not applicable during the postnatal period, and (e) a high failure rate of 9 per 100 woman-years (96). The failures are due to wrong calculation, inability to follow calculations, irregular use and "taking chances".

Two medical complications have been reported to result from the use of safe period; ectopic pregnancies and embryonic abnormalities. Ectopic pregnancies may follow conception late in the menstrual cycle and displacement of the ovum; embryonic abnormalities may result from conception involving either an over-aged sperm or over-aged ovum. If this is correct, the safe period may not be an absolutely safe period (96).
4. Natural family planning methods

The term “natural family planning” is applied to three methods: (a) basal body temperature (BBT) method, (b) cervical mucus method, and (c) symptothermal method. The principle is the same as in the calendar method, but here the woman employs self-recognition of certain physiological signs and symptoms associated with ovulation as an aid to ascertain when the fertile period begins. For avoiding pregnancy, couples abstain from sexual intercourse during the fertile phase of the menstrual cycle; they totally desist from using drugs and contraceptive devices. This is the essence of natural family planning.

(a) Basal body temperature method (BBT)

The BBT method depends upon the identification of a specific physiological event—the rise of BBT at the time of ovulation, as a result of an increase in the production of progesterone. The rise of temperature is very small, 0.3 to 0.5 degrees C. When no ovulation occurs (e.g., as after menarche, during lactation) the body temperature does not rise. The temperature is measured preferably before getting out of bed in the morning. The BBT method is reliable if intercourse is restricted to the post-ovulatory infertility period, commencing 3 days after the ovulatory temperature rise and continuing up to the beginning of menstruation. The major drawback of this method is that abstinence is necessary for the entire pre-ovulatory period. Therefore, few couples now use the temperature method alone (97).

(b) Cervical mucus method

This is also known as “billings method” or “ovulation method.” This method is based on the observation of changes in the characteristics of cervical mucus. At the time of ovulation, cervical mucus becomes watery clear resembling raw egg white, smooth, slippery and profuse. After ovulation, under the influence of progesterone, the mucus thickens and lessens in quantity. It is recommended that the woman uses a tissue paper to wipe the inside of vagina to assess the quantity and characteristics of cervical mucus. To practice this method the woman should be able to distinguish between different types of mucus. This method requires a high degree of motivation than most other methods. The appeal and appropriateness of this method in developing countries such as India, especially among lay people, is dubious.

(c) Symptothermal method

This method combines the temperature, cervical mucus and calendar techniques for identifying the fertile period. If the woman cannot clearly interpret one sign, she can “double check” her interpretation with another. Therefore, this method is more effective than the “Billings method.”

To sum up, natural family planning demands discipline and understanding of sexuality. It is not meant for everybody. The educational component is more important with this approach than with other methods. The opinion of the Advisory Group to WHO’s Special Programme of Research in Human Reproduction is that the current natural family planning methods have very little application particularly in developing countries (98).

5. Breast-feeding

Field and laboratory investigations have confirmed the traditional belief that lactation prolongs postpartum amenorrhea and provides some degree of protection against pregnancy (99). No more than 5–10 per cent of women conceive during lactational amenorrhea, and even this risk exists only during the month preceding the resumption of menstruation (100). However, once menstruation returns, continued lactation no longer offers any protection against pregnancy (101). By and large, by 6 months after childbirth, about 20–50 per cent of women are menstruating and are in need of contraception (102).

6. Birth control vaccine

Several immunological approaches for men and women are being investigated. The most advanced research involves immunization with a vaccine prepared from beta sub-unit of human chorionic gonadotropin (hCG), a hormone produced in early pregnancy. Immunization with hCG would block continuation of the pregnancy. Antibodies appeared in about 4–6 weeks and reached maximum after about 5 months and slowly declined reaching zero levels after a period ranging from 6–11 months. The immunity can be boosted by a second injection. Two types of pregnancy vaccines employing variants of the beta sub-unit of hCG are now about to go into clinical trial (51). Research on birth control vaccines continues. The uncertainties are great (86).

TERMINAL METHODS

(Sterilization)

Voluntary sterilization is a well-established contraceptive procedure for couples desiring no more children. Currently female sterilizations account for about 85 per cent and male sterilizations for 10–15 per cent of all sterilizations in India (103), inspite of the fact that male sterilization is simpler, safer and cheaper that female sterilization.

Sterilization offers many advantages over other contraceptive methods—it is a one-time method; it does not require sustained motivation of the user for its effectiveness; provides the most effective protection against pregnancy; the risk of complications is small if the procedure is performed according to accepted medical standards; and it is most cost-effective. It has been estimated that each procedure averts 1.5 to 2.5 births per woman (104).

Guidelines for sterilization

Sterilization services are provided free of charge in Government institutions. Guidelines have been issued from time to time by the Government covering various aspects of sterilization. These are (105, 106):

a. The age of the husband should not ordinarily be less than 25 years nor should it be over 50 years.

b. The age of the wife should not be less than 20 years or more than 45 years.

c. The married couple must have 2 living children at the time of operation.

d. If the couple has 3 or more living children, the lower limit of age of the husband or wife may be relaxed at the discretion of the operating surgeon.
e. It is sufficient if the acceptor declares having obtained the consent of his/her spouse to undergo sterilization operation without outside pressure, inducement or coercion, and that he/she knows that for all practical purposes, the operation is irreversible, and also that the spouse has not been sterilized earlier.

Male sterilization (107, 108)

Male sterilization or vasectomy being a comparatively simple operation can be performed even in primary health centres by trained doctors under local anaesthesia. When carried out under strict aseptic technique, it should have no risk of mortality. In vasectomy, it is customary to remove a piece of vas at least 1 cm after clamping. The ends are ligated and then folded back on themselves and sutured into position, so that the cut ends face away from each other. This will reduce the risk of recanalization at a later date. It is important to stress that the acceptor is not immediately sterile after the operation, usually until approximately 30 ejaculations have taken place (44). During this intermediate period, another method of contraception must be used. If properly performed, vasectomies are almost 100 percent effective.

Following vasectomy, sperm production and hormone output are not affected. The sperm produced are destroyed intraluminally by phagocytes. This is a normal process in the male genital tract, but the rate of destruction is greatly increased after vasectomy. Vasectomy is a simpler, faster and less expensive operation than tubectomy in terms of instruments, hospitalization and doctor’s training. Cost-wise, the ratio is about 5 vasectomies to one tubal ligation.

COMPLICATIONS

The very few complications that may arise are:

(a) Operative: The early complications include pain, scrotal haematoma and local infection. Wound infection is reported to occur in about 3 percent of patients. Good haemostasis and administration of antibiotics will reduce the risk of these complications.

(b) Sperm granules: Caused by accumulation of sperm, these are a common and troublesome local complication of vasectomy. They appear in 10-14 days after the operation. The most frequent symptoms are pain and swelling. Clinically the mass is hard and the average size approximately 7 mm. Sperm granules may provide a medium through which re-anastomosis of the severed vas can occur. The sperm granules eventually subside. It has been reported that using metal clips to close the vas may reduce or eliminate this problem.

(c) Spontaneous recanalization: Most epithelial tubes will recanalize after damage, and the vas is no exception. The incidence of recanalization is variously placed between 0 to 6 percent. Its occurrence is serious. Therefore, the surgeon should explain the possibility of this complication to every acceptor prior to the operation, and have written consent acknowledging this fact. In a study, the wives of 6 out of 14,047 men who had vasectomies in the UK became pregnant between 16 months and 3 years later (109). Therefore, the patient should be urged to report for a regular follow-up, may be up to 3 years.

(d) Autoimmune response: Vasectomy is said to cause an autoimmune response to sperm. Blocking of the vas causes reabsorption of spermatocytes and subsequent development of antibodies against sperm in the blood. Normally 2 percent of fertile men have circulating antibodies against their own sperm. In men who have had vasectomies, the figure can be as high as 54 percent. There is no reason to believe that such antibodies are harmful to physical health. It is likely that the circulating antibodies can cause a reduction in subsequent fertility despite successful near-sterilisation of the vas (43).

(e) Psychological: Some men may complain of diminution of sexual vigour, impotence, headache, fatigue, etc. Such adverse psychological effects are seen in men who have undergone vasectomy under emotional pressure. That is why it is important to explain to each acceptor the basis of the operation and give him sufficient time to make up his mind voluntarily and seriously to have the operation done.

Causes of failure (108)

The failure rate of vasectomy is generally low. 0.15 per 100 person-years. The most common cause of failure is due to the mistaken identification of the vas. That is, instead of the vas, some other structure is the spermatic cord such as thrombosed vein or thickened lymphatic has been taken. Histological confirmation has, therefore, been recommended on all vasectomy specimen by some authors in developed countries. In developing countries, histological confirmation is ruled out because of lack of facilities for such an examination. A simpler method has been recommended, that is, microscopic examination of a smear prepared by gentle squeezing of the vas on a glass slide and staining with Wright’s stain. The vas can be identified by the presence of columnar epithelial cells that line the lumen of the vas. In some cases, failure may be due to spontaneous recanalisation of vas. Sometimes there may be more than one vas on one side. Pregnancy could also result from sexual intercourse before the disappearance of sperms from the reproductive tract.

Post-operative advice

To ensure normal healing of the wound and to ensure the success of the operation, the patient should be given the following advice:

1. The patient should be told that he is not sterile immediately after the operation; at least 30 ejaculations may be necessary before the seminal examination is negative (44).
2. To use contraceptives until spermia has been established.
3. To avoid taking bath for at least 24 hours after the operation.
4. To wear a T-bandage or scrotal support (langeron) for 15 days: and to keep the site clean and dry.
5. To avoid cycling or lifting heavy weights for 15 days; there is, however, no need for complete bed rest.
6. To have the stitches removed on the 5th day after the operation.

No scalpel vasectomy

No scalpel vasectomy is a new technique that is safe, convenient and acceptable to males. This new method is now being canvassed for men as a special project, on a voluntary basis under the family welfare programme. Under
the project, medical personnel all over the country are to be trained. Availability of this new technique at the peripheral level will increase the acceptance of male sterilisation in the country. The project is being funded by the UNFPA (19).

Female sterilization

Female sterilization can be done as an interval procedure, postpartum or at the time of abortion. Two procedures have become most common, namely laparoscopy and minilaparotomy.

(a) Laparoscopy

This is a technique of female sterilization through abdominal approach with a specialized instrument called "laparoscope." The abdomen is inflated with gas (carbon dioxide, nitrous oxide or air) and the instrument is introduced into the abdominal cavity to visualize the tubes. Once the tubes are accessible, the Fallopian tubes (or clips) are applied to occlude the tubes. This operation should be undertaken only in those areas where specialist obstetrician–gynaecologists are available. The short operating time, shorter stay in hospital and a small scar are some of the attractive features of this operation.

Patient selection: Laparoscopy is not advisable for postpartum patients for 6 weeks following delivery; however, it can be done as a concurrent procedure to MTP. Haemoglobin per cent should not be less than 8. There should be no associated medical disorders such as heart disease, respiratory disease, diabetes and hypertension. It is recommended that the patient be kept in hospital for a minimum of 48 hours after the operation.

The cases are required to be followed-up by health workers (F) LHV's in their respective areas once between 7–10 days after the operation, and once again between 12 and 18 months after the operation.

Complications: Although complications are uncommon, when they do occur they may be of a serious nature requiring experienced surgical intervention. Puncture of large blood vessels and other potential complications have been described as major hazards of laparoscopy. Laparoscopic sterilizations have become very popular in India. Nearly 4.1 per cent of all female sterilizations during 2010–11 were through laparoscopic method (24).

(b) Minilaparotomy

Minilaparotomy is a modification of abdominal tubectomy. It is a much simpler procedure requiring a smaller abdominal incision of only 2.5 to 3 cm conducted under local anaesthesia. The minilaparotomy technique is considered an evolutionary procedure for female sterilization. It is also found to be a suitable procedure at the primary health centre level and in mass campaigns. It has the advantage over other methods with regard to safety, efficiency and ease in dealing with complications. Minilaparotomy operation is suitable for postpartum tubal sterilization.

Evaluation of contraceptive methods

Contraceptive efficacy is generally assessed by measuring the number of unplanned pregnancies that occur during a specified period of exposure and use of a contraceptive method. The two methods that have been used to measure contraceptive efficacy are the Pearl index and life-table analysis.

The Pearl index is defined as the number of "failures per 100 woman-years of exposure (HWY)." This rate is given by the formula:

\[ \text{Failure rate per HWY} = \frac{\text{Total accidental pregnancies}}{\text{Total months of exposure}} \times 1200 \]

In applying the above formula, the total accidental pregnancies shown in the numerator must include every known conception, whatever its outcome, whether this had terminated as live births, stillbirths or abortions or had not yet terminated. The factor 1200 is the number of months in 100 years. The total months of exposure in the denominator is calculated by subtracting from the period under review of 10 months for a full-term pregnancy, and 4 months for an abortion (96).

In designing and interpreting a use-effectiveness trial, a minimum of 600 months of exposure is usually considered necessary before any firm conclusion can be reached (96).

With most methods of contraception, failure rates decline with duration of use. The Pearl index is usually based on a specific exposure (usually one year) and, therefore, fails to accurately compare methods at various durations of exposure. This limitation is overcome by using the method of life-table analysis.

Life-table analysis: Life-table analysis calculates a failure rate for each month of use. A cumulative failure rate can then be compared for methods at any specific length of exposure. Women who leave a study for any reason other than unintended pregnancy are removed from the analysis, contributing their exposure until the time of the exit.

Element of success in family planning programme

The main strategy of family planning programme is to offer to client easy access to a wide range of affordable contraceptive method through multiple service delivery channels in a good quality; reliable fashion. The key points are as follows: (1) Make services accessible: Offering services through a variety of delivery points makes methods available to more potential users; (2) Make services affordable: Partnerships between public and private-sector services encourage clients to pay what they can, while public programmes serve the poor for free or for low fees; (3) Offer client-centered care: Planning and providing services with the clients in mind help to make sure their needs are met and their preferences are honoured; (4) Rely on evidence-based technical guidance: Up-to-date service delivery guidelines, tools, and job aids can help translate research findings into better practice; (5) Communicate effectively: Communication grounded in behaviour theory and sensitive to local norms motivates clients to seek services and helps them make good family planning choices; (6) Ensure contraceptive security: A strong logistic system and a long-term plan for contraceptive security ensure that a variety of methods, and the supplies and equipment to provide them, are always available; (7) Work for supportive policies: Showing how family planning contributes to development goals makes the case for continued support for family planning.
planning programme; (8) Coordinate: When governments, donor agencies, and implementing partners work together, they streamline efforts and avoid duplication; (9) Build a high-performing staff: Programme can keep workers motivated and on the job by creating a good working environment, matching skills with tasks, and rewarding a job well done; (10) Secure adequate budget, use it well: Spending wisely, doing more with less, and finding ways to recover costs can help ensure financial sustainability; (11) Base decisions on evidence: Research, monitoring, and evaluation yield important information to guide decision-making, and they need not be expensive; (12) Lead strongly, manage well: Strong leadership helps programmes navigate change. Good management solves operational problems; and (13) Integrate services appropriately: Programmes can address a wider range of health needs by integrating services where appropriate and offering referrals where it is not.

Unmet need for family planning (110)

The concept that eventually became unmet need for family planning was first explored in 1960s, when data from surveys of contraceptive knowledge, attitude and practices (KAP) showed a gap between some women's reproductive intention and their contraceptive behaviour. The term that came to popular use describing this gap was "KAP-gap". One of the first published use of the term "unmet need" appeared in 1977. In 1978, based on World Fertility Survey data from five Asian countries, Charles Westoff published first comparative estimates of unmet need for limiting births.

Many women who are sexually active would prefer to avoid becoming pregnant, but nevertheless are not using any method of contraception (including use by their partner). These women are considered to have an "unmet need" for family planning. The concept is usually applied to married women. However, it can apply to sexually active, fecund women and perhaps to men, but its measurement has been limited to married women only. Unmet need can be a powerful concept for family planning. It poses a challenge to family planning programme – to reach and serve millions of women whose reproductive attitude resembles those of contraceptive users, but who are, for some reason or combination of reasons, not using contraceptives.

Among the most common reason for unmet need is inconvenient or unsatisfactory services, lack of information, fears about contraceptive side-effects and opposition from husband or relatives. Unmet need is defined on the basis of women's response to survey questions.

According to the National Family Health Survey–3, the unmet need for family planning is highest (27.1 per cent) among women below 20 years of age and is almost entirely for spacing the births rather than for limiting the births. It is also relatively high for women in age group 20–24 years (21.1 per cent) with about 75 per cent of the need being for spacing births. The unmet need for contraception among women aged 30 years and above are mostly for limiting the births.

Unmet need for family planning is higher in rural areas than in urban areas. It also varies by women's education (within range of 10.4–13.6 per cent) and religion (Hindu and Christian women have a lower unmet need than Muslim women). Table 24 shows some of the characteristics of unmet need for family planning in India (17).

Source: (17)

The National Family Health Survey–3 results show that although current use of contraception has increased and the extent of unmet need has declined in most of the states in India, there is a need for considerable improvement in the coverage and quality of family planning services, especially in the four large states of Uttar Pradesh, Bihar, Madhya Pradesh and Rajasthan.

According to the DLHS-III (2007–08), about 20.5 per cent of currently married women in India have an unmet need for family planning. The unmet need for spacing the births is about 7.2 per cent and need for limiting births is 13.3 per cent (112).

Contraception and adolescence (113)

Adolescence is a period between puberty and the end of physiological maturation, which occurs between ages 15–19 years. Pregnancy in adolescence constitutes about 11 per cent of all births in most developing countries and in some developed countries such as the USA. For the
year 2014, WHO puts the global adolescent birth rate at 49 per 1000 girls of that age, country rates range from one to 200 per 1000 girls. This indicates a marked decrease since 1990 (111). These are often "at risk" pregnancies. Many are undesired, and occur in unmarried adolescents who then resort to illegal or quack medical interventions performed under unsatisfactory medical conditions. This has serious health and even life-threatening consequences for these young women - the ensuing mortality and morbidity (especially secondary sterility) are quite considerable.

Prevention of undesired pregnancies and of sexually transmitted diseases in young people through educational programmes dealing with responsible sexual behaviour is a major public health challenge. Adolescents are ambivalent about family planning - to request contraception is to "reveal" one's sexuality. For this reason, adolescents sometimes choose the risk of an undesired pregnancy and of an abortion.

BARRIER METHODS: Condoms make barrier method worthwhile, because they protect those adolescents, with occasional sexual partners, against STD and AIDS. However, condoms must be properly used, and it depends on the man's behaviour. Young men seem to be increasingly aware of the importance of safeguarding their own health and that of their partners. Cervical caps and diaphragms, on the other hand, are inappropriate for adolescents since they require foresight of intercourse and complicated manipulations, to which young people are loath.

HORMONAL CONTRACEPTION: Hormonal methods are perfectly suitable for adolescents, who generally do not suffer from such problems as cardiovascular contraindications. In fact, these are probably the most adequate methods, since they are completely reversible, and in no way disturb the future fertility of these young women. In developed countries, pills are usually preferred, but trimestrial or monthly injections are also appropriate. Implants, with their five year term, cover too long a period for certain adolescents.

IUD: IUD are theoretically contraindicated, because of the risk of pelvic infection and of secondary sterility. However, an adolescent is better protected by an IUD than by illegal repeated abortions. This method has the advantage of being discrete and avoiding demanding routines.

OTHER METHODS: Periodic abstinence is not easy when cycles are irregular and intercourse is unforeseen, and with new partners. In certain countries, however, they are practically the only method taught, for religious reasons, and poor protection is preferable to no protection at all. Similarly, withdrawal is not very suitable method, since young men are usually not very skillful.

Spermicides are not contraindicated, but have two disadvantages - they are costly, and are not effective against STD and AIDS.

As a major chunk of the world population is under 25 years age group. An extremely large number of young people will, therefore, be entering their reproductive years at that time. The demographic future of the world will depend on them, on how well informed they are, and on their sense of responsibilities.

DELIVERY SYSTEM

Since family planning is essentially a component of the health care system, the primary responsibility for the delivery of services rests with the Government through its health care system at the Centre and in the States.

At the Centre

The Family Welfare Programme is a centrally sponsored scheme, and the states receive 10% per cent assistance from the central government. Since the entire cost is virtually borne by the central government, the central government controls the planning, and financial management of the programme (e.g., establishment of clinics, pattern of staffing, expenditure); training, research and evaluation, and most important, the formulation of an overall policy for the programme. The current policy is to promote family planning on the basis of voluntary and informed acceptance with full community participation. The emphasis is on a 2-child family. Recently there have been two major changes in the approach to delivery of family planning services: first, a greater emphasis on spacing methods, side by side with terminal methods, and secondly to take the services to every door-step and motivate families to adopt the small family norm.

The administrative apparatus consists of a separate Department of Family Welfare, which was created in 1966 in the Central Ministry of Health and Family Welfare. The Secretary to the Government of India in the Ministry of Health and Family Welfare is in overall charge of the Department of Family Welfare. He is assisted by a Special Secretary and Joint Secretaries. The special secretary supervises the programme implementation and coordinates the various activities. There is now an Advisor (Mass Media and Communication) - an officer of the rank of an Additional Secretary. The National Institute of Health and Family Welfare acts as an apex technical institute for promoting health and family welfare in the country through education, training services, research and evaluation. There is a Central Family Welfare Council consisting of all the State Health Ministers to review the implementation of the programme. A Population Advisory Council headed by the Union Health Minister, Members of Parliament, and persons from the fields related to population control was set up in 1982. This body acts like a "think tank" to analyze the implementation of the programme and advise the government suitably. A cabinet sub-committee headed by the Prime Minister has also been formed for periodic review of the progress of the family welfare programme. Family planning is no longer viewed as the sole responsibility of the Health Ministry, but will be devolved on all ministries connected with human resources and development. This is an important breakthrough in current thinking.

At the state level

Under the Indian constitution, the state governments are responsible for the administration and implementation of the Family Welfare Programme. Since most of the crucial policy decisions are made by the central government, the pattern of organization and many features of the delivery system are fairly well-standardized in the States.

The organizational set-up at the State level consists of a State Family Welfare Bureau, which is part of the State Health and Family Welfare Directorate. At present, 25 State Family Welfare Bureaus are functioning in the country.

In 1979, the offices of the Family Welfare and National Malaria Eradication Programme were merged into one office and named as Regional Office for Health and Family Welfare. These regional offices have been set up to maintain
liaison with state governments and give technical assistance to them in connection with the implementation of the Family Welfare Programme and other important health programmes. To co-ordinate the family welfare activities between the state governments and the central government, one Family Welfare Cell has been sanctioned for each State.

At the district level

At the district level, the set-up consists of a District Family Welfare Bureau consisting of 3 divisions – an administrative division headed by the District Family Welfare Officer; main education and media division, in charge of District Mass Education and Media Officer; and an evaluation division, in charge of a Statistical Officer. There are supported by 1,085 Urban Family welfare centres and 871 Urban Health Posts. Presently there are 4 types of Urban Health Posts-type A for areas with population less than 5,000, type B for areas with population between 5,000–10,000, type C for population between 10,000–25,000, and type D for areas with population between 25,000–50,000. If the population is more than 50,000, then it is to be divided into sectors of 50,000 population and Health Posts provided. Type A, B and C Health Posts are attached to a hospital for providing referral and supervisory services. Type D Health Post is attached to a hospital for sterilization, MTP and referral (34). Only type D health post have a post of medical officer.

The 10 city family welfare bureaus are entrusted with the responsibility of coordination, monitoring and supervision etc. of the family welfare services provided by various institutions in the city. Presently there are three types of Urban Family Welfare Centre. Type I is for population between 10,000–25,000, type II is for population between 25,000–50,000, and type III is for above 50,000 population (34). These are manned by 2 para-medical staff in type I and II centres and 6 persons including medical officer in type III centres.

The Urban family welfare centres and health posts provide comprehensive integrated services of MCH and family planning. The staff pattern is different for different types of health posts and urban family welfare centres.

At the community health centre

Community health centre is established and maintained by the state governments. Presently it is manned by four medical specialists i.e. surgeon, physician, gynaecologist and paediatrician, supported by 21 para-medical and other staff. It has 20 in-door beds with one OT. X-ray, labour room and laboratory facilities and serves as a referral centre for four PHCs. According to Indian Public Health Standards, the community health centre is to be manned by 6 medical specialists including an anaesthetist and an eye surgeon supported by 24 paramedical and other staff with inclusion of two nurse midwives. It provides, apart from other emergency obstetric care, full range of family planning services including laproscopic services and safe abortion services. At present as of March 2014, 5,363 community health centres are functional in the country (114).

At the primary health centre

Since more than 68.2 per cent of India’s population lives in the rural areas an adequate network of service centres has been extended to the rural areas. A Rural Family Welfare Centre with a medical officer and supporting staff forms an integral part of the primary health centre. A total of 5,435 Rural Family Welfare Centres were established in the country at all block level PHCs sanctioned up to 1.4.1980. Most of the states have integrated these centres into their primary health care system, and after this date family planning services are being provided through integrated facilities at PHCs (115). As of March 2014, 25,020 primary health centres were functioning in the country. Each centre is supported by sub-centres. The total number of sub-centres functioning are 152,326 (114).

When fully staffed (by 3 medical officers including one lady doctor and supporting personnel) the PHC is expected to provide fairly comprehensive “essential health care” including family planning care. The medical officers are usually trained to provide MTP and sterilization services. The programme of insertion of copper-T IUDs has been intensified. It is intended that laparoscopic services which were so popular will be made more widely available at the PHC.

The sub-centres are to provide the main thrust of the programme. Each subcentre is staffed by one male and one female health worker. They are responsible for providing rudimentary health and MCH care; family planning motivation, supplies and services in spacing methods.

Various studies conducted have highlighted that the existing infrastructure is not being optimally utilized because of its inadequacy to provide proper services. To improve matters popular committees have been set up at all levels by some states to involve people in the programme and in exercising vigilance over the work of various functionaries.

At the village level

Two schemes are being implemented at the village level to improve the outreach of services and increase local participation: (a) The Village Health Guides: An innovative approach has been the creation of a band of village Health Guides (mostly women), one for each village or a population of 1000. They are made responsible for spreading knowledge and information to the eligible couples and providing them with supplies of Nirodh and oral pills. About 3.25 lakh health guides are already in position. (b) Trained dais: The national target is to provide one trained dais per 1000 population. They conduct safe deliveries in rural areas. They also act as family planning counsellors and motivators, supplementing the delivery by becoming ASHA (8.89 lakh ASHAs have been selected so far and 8.06 lakh have been provided with drug kits (112)). At present the village health guides, trained dais and ASHAs are the lynchpins of the family planning delivery system in India.

New initiatives (112)

1. Home Delivery of Contraceptives (HDC)
   a. A new scheme has been launched to utilize the services of ASHA to deliver contraceptives at the doorstep of beneficiaries. The scheme was launched in 235 pilot districts of 17 States on 11 July 2011 and is now expanded to the entire country from 17th December 2012.
   b. ASHA is charging a nominal amount from beneficiaries for her effort to deliver contraceptives at doorstep i.e. Rs. 1 for a pack of 3 condoms; Rs. 1 for a cycle of OCPs and Rs. 2 for a pack of one tablet of ECP.
2. Ensuring Spacing at Birth (EBS):

- Under a new scheme launched by the Government of India, services of ASHAs to be utilized for counselling newly married couples to ensure spacing of 2 years after marriage and couples with 1 child to have spacing of 3 years after the birth of 1st child. The scheme is operational in 18 States (EAG, North-Eastern and Haryana). ASHA would be paid following incentives under the scheme:
  - Rs. 500/- to ASHA for delaying first child birth by 2 years after marriage.
  - Rs. 1000/- in case the couple opts for a permanent limiting method up to 2 children only.

- Ministry of Health & Family Welfare has introduced short term IUdC (5 years effectively), Cu IUdC 375 under the National Family Planning programme. Training of State level trainers has already been completed and process is underway to train service providers up to the sub-centre level.
- A new method of IUdC insertion (post-partum IUdC insertion) has been introduced by the Government.
- Promoting Post partum Family Planning services at district hospitals by providing for placement of dedicated Family Planning Counsellors and training of personnel.

3. Pregnancy Testing Kits

Nischay-Hone based pregnancy test kits (PTKs) was launched under NRHM in 2008 across the country. The

PTKs are being made available at sub-centres and to the ASHAs to facilitate the early detection and decision making for contraceptive practice.

The public sector provides a wide range of contraceptive services for limiting and spacing of births at various levels of health system as described in Table 25.

Government of India is promoting "Fixed Day Static Services" (FDSS) approach in sterilization services within the public health system with the aim of increasing access to sterilization services. States are being provided technical and financial support for the development of human resources and upgradation of health facilities for the functioning of FDSS. In the states with high unmet need for limiting methods, sterilization camps will continue till the time FDSS is implemented effectively. The frequency of sterilization services at different health facilities at FDSS is as follows:

- District hospital - weekly
- Sub-district hospital - weekly
- CHC/Block PHC - fortnightly
- 26x7 PHC/PHC - monthly

Community Needs Assessment Approach (116)

Till recently, the achievements of family welfare programme were assessed on the basis of the targets given from the centre for individual contraceptive. This led to a situation where the achievement of the contraceptive targets had become the ends by themselves. Over the years it became apparent that there were many drawbacks in the top down target approach in which types and quantity of contraceptive need to be canvassed was decided by the higher authorities. Firstly, the user preference was not

reflected in the targets. If the contraceptive required in accordance with the user was not available, the targets were not likely to be achieved. There was no authentic system of feedback regarding which type of contraceptive was to be promoted in a particular area or among a particular age group. Secondly, the quality of the services became secondary. For example, if in an attempt to fulfill targets for the number of IUD insertions, the quality of care is compromised (especially while screening women for pre-existing reproductive tract infections and sexually transmitted diseases before IUD insertion) the acceptability of IUD programme would receive a serious setback and discontinuation rate will be high. Thirdly, people may be tempted to resort to false reporting to claim fulfilment of the target. In other words, contraceptive targets and cash incentives resulted in the inflation of performance statistics and deterioration in the quality of services.

Government of India deliberated objectively on the utility of retaining the practice of targets at national and state levels. In the year 1995-96, one district in each of 18 states (including a pilot project in Kerala and Tamil Nadu) were made target free. Later on the practice of fixing up of targets for individual contraceptive method was given up from April 1996. This does not mean a licence to do no work. The population goals remain the same as before. Health workers are expected to consult families and local community in the beginning of the year in order to assess their needs and preference and then work out for themselves the programme and workload for the coming year. The requirement for each village needs to be worked out to arrive at the workload for the ANM, this becomes the target for the ANM for the year. The workload of different ANMs under one PHC when added up would determine the workload for the PHC. Similarly requirements at the district level would be worked out by adding up the requirements at all the PHCs.

Later on it was found that due to complex calculations required the health workers were unable to fix the performance norms for themselves. Therefore, it was decided to modify and rename the target free manual as Community Needs Assessment Approach Manual.

Involvement of private sector

The family planning programme, to be successful, will have to be extended beyond the government delivery system to include the private sector. Grants-in-aid are provided to voluntary organizations and industrial organizations for running family welfare centres and postpartum centres. The scheme for involvement of private medical practitioners in the family welfare programme has been extended to practitioners of integrated medicine. Government has also created nation-wide retail outlets for selling subsidized condoms.

Incentives and dis-incentives

The use of incentives and dis-incentives to encourage couples to practise family planning has become a common strategy in many developing countries. Financial compensation of individuals undergoing sterilization was first introduced in 1966; over the years, it has been gradually increased. The acceptors now receive a one-time payment of Rs. 600 for conventional tubectomy, Rs. 1100 for vasectomy and Rs. 145 for laparoscopic tubectomy, and Rs. 75 are given to IUD acceptors. Motivators also receive a small amount (Rs. 150 for tubectomy and Rs. 200 for vasectomy). State government employees, who undergo sterilization after two or three children are eligible for a special incentive. Thus two incentives after 2 children and one after 3 children. Central government employees get one increment after sterilization. 'It is under the scheme introduced in Dec. 1979 to promote small family norm, provided the employee is below 50 years of age and his spouse below 45 years. They get special leave (14 days for women and 7 days for men). No maternity leave is allowed after 3 children.

In the event of death following sterilization, recanalization, or IUD insertion, ex-gratia payment of Rs. 50,000 has been authorised to be paid to the surviving spouse, natural heir, etc. Rs. 30,000 per case of incapacitation and Rs. 20,000 per case of death of serious post-operative complications (9).

The State Governments have been requested to issue Green Cards to individual acceptors of terminal methods after two children as a mark of recognition and for priority attention in schemes where preferential treatment was feasible. Cash awards have been instituted for the best performing states, the amount of which will be spent on promoting family welfare activities (117).

Family welfare linked health insurance scheme (9)

Government of India has introduced a family planning insurance scheme for acceptors of sterilization and indemnity cover for doctors performing sterilization procedures in both government and accredited private/ NGO managed health care facilities. The insurance scheme will be operated by the ICICI.

Compensation in the event of death:

In the event of death following sterilization (inclusion of death during process of sterilization operation) in hospital or within 7 days from the date of discharge from the hospital, the compensation available is Rs. 2 lakh. Death following sterilization within 8-30 days from the date of discharge from the hospital, the compensation is Rs. 50,000 and the compensation for failure of sterilization operation is Rs. 30,000 and Rs 85,000 for medical complication occurring within 60 days of sterilization operation (to be reimbursed on the basis of actual expenditure incurred, not exceeding Rs 25,000) (92).

At the doctors and health facilities rendering family planning services, conducting such operations shall stand indemnified against claims arising out of failure of sterilization, death or medical complications resulting therefrom to a maximum amount of Rs. 2 lacs per doctor/ health facility per case. The cover would also include the legal costs and actual cost of defending the prosecuted doctor/ health facility in court, which would be borne by the insurance company, subject to certain limits (118).

Postpartum Programme (119)

An All India Hospital Postpartum Programme (AHPPP) was introduced in 1969. It is a hospital-based, maternity-centred approach to family planning. The primary objective of the postpartum programme is to improve the health of the mother and children through MCH and Family Welfare programme which includes antenatal, neonatal, and postnatal services; immunization services to children and mothers; and prophylaxis against anemia and blindness. The programme is based on the following rationale:
The problem of family planning is, therefore, essentially the problem of social change. Contraceptive technology is no short cut to the problem. What is most important is to stimulate social changes affecting fertility such as raising the age of marriage, increasing the status of women, education and employment opportunities, old age security, compulsory education of children, accelerating economic changes designed to increase the per capita income, etc. It is now axiomatic that economic development is the best contraceptive. The experience of all countries which have had a successful population control show that the best motivation is economic, a desire to improve standards of living. The solution to the problem is one of mass education and communication, so that people may understand the benefits of a small family.

VOLUNTARY ORGANIZATIONS

Voluntary organizations have played a major role in population control programmes since the beginning. They are involved in every possible way so as to complement governmental efforts to promote Family Welfare Programme. Apart from educational and motivational efforts, their activities include running of Family Welfare Centres, post-partum centres, ANM training schools, population research centres and other innovative projects.

Some of the well-known voluntary agencies in India are the Family Planning Association of India, the Family Planning Foundation and the Population Council of India. Others include the Indian Red Cross, the Indian Medical Association, Rotary Clubs, Lion Clubs, Citizens Forum, Christian organisations and others.

At the international level, the International Planned Parenthood Federation is the world’s largest private voluntary organization supporting family planning services in developing countries. It is an international federation of independent Family Planning Associations with headquarters in London. Others with long experience in this field include the United Nations Fund for Population Activities (UNFPA), the US Agency for International Development (USAID), the Population Council, Ford Foundation, the Pathfinder Fund and World Bank besides WHO and UNICEF. The international agencies are assisting in funding family planning research, service, training and information programmes designed to reduce the family size.

NATIONAL FAMILY WELFARE PROGRAMME

India launched a nation-wide family planning programme in 1952, making it the first country in the world to do so, though records show that birth control clinics have been functioning in the country since 1930. The early beginnings of the programme were modest with the establishment of a few clinics and distribution of educational material, training and research. During the Third Five Year Plan (1961–66), family planning was declared as “the very centre of planned development”. The emphasis was shifted from the purely “clinic approach” to the more vigorous “extension education approach” for motivating the people for acceptance of the “small family norm”. The introduction of the Lippes Loop in 1965 necessitated a major structural reorganisation of the programme, leading to the creation of a separate Department of Family Planning in 1965 in the Ministry of Health. During the years 1966–69, the programme took firmer roots. The family planning infrastructure (e.g., primary health centres, sub-centres,
urban family planning centres, district and State bureaus, was strengthened. During the Fourth Five Year Plan (1969–74), the Government of India gave "top priority" to the programme. The Programme was made an integral part of MCH activities of PHCs and their sub-centres. In 1970, an All India Hospital Postpartum Programme and in 1972, the Medical Termination of Pregnancy (MTP) Act were introduced. During the Fifth Five Year Plan (1975–80) there have been major changes. In April 1976, the country framed its first “National Population Policy”. The disastrous forcible sterilization campaign of 1976 led to the Congress defeat in the 1977 election. In June 1977, the newly formed Janata Government that came into power formulated a new population policy, ruling out compulsion and coercion for all times to come. The Ministry of Family Planning was renamed “Family Welfare”.

Although the performance of the programme was low during 1977–78, it was a good year as much as the programme moved into new healthier directions. The 42nd Amendment of the Constitution has made “Population control and Family Planning” a concurrent subject, and this provision has been made effective from January 1977. The acceptance of the programme is now purely on voluntary basis. The launching of the "Rural Health Scheme in 1977 and the involvement of the local people (e.g., Health Guides, trained Dass, Opinion leaders) in the family welfare programme at the grass-root level were aimed at accelerating the pace of progress of the programme. India was a signatory to the Alma Ata Declaration in 1978. The acceptance of the primary health care approach to the achievement of HFA/2000 AD led to the formulation of a National Health Policy in 1982. The National Health Policy was approved by the Parliament in 1983. It laid down the long-term demographic goal of NRR-1 by the year 2000 – which implies a 2-child family norm – through the attainment of a birth rate of 21 and a death rate of 9 per thousand population, and a couple protection rate of 60 per cent by the year 2000. The Sixth and Seventh Five Year Plans were accordingly set to achieve these goals. The National Health Policy also called for restructuring the health care delivery system to achieve HFA/2000 AD, and family planning had been accorded a central place in health development.

The Universal Immunization Programme aimed at reducing mortality and morbidity among infants and young children due to vaccine-preventable diseases was started in the year 1985–86. The oral rehydration therapy was also started in view of the fact that diarrhea was a leading cause of death among children. Various other programmes under MCH were also implemented during the Seventh Five Year Plan. The objective of all these programmes was convergent and aimed at improving the health of the mothers and young children, and to provide them facilities for prevention and treatment of major diseases. During 1992 these programmes were integrated under Child Survival and Safe Motherhood (CSSM) Programme.

The process of integration of related programmes initiated was taken a step further during 1994 when the International Conference on Population and Development in Cairo, recommended Implementation of Unified Reproductive and Child Health Programme (RCH). It is obviously sensible that integrated RCH programme would help in reducing cost of inputs to some event because overlapping of expenditure would no longer be necessary and outcome will be better. Accordingly, during Ninth Five Year Plan the RCH Programme integrates all the related programmes of the Eighth Five Year Plan. The concept of RCH is to provide need based, client oriented, demand driven, high quality integrated services.

The investment on family welfare programme during successive plan-periods is tabulated below [221]. It can be seen that from a modest sum of 0.65 crores during the first plan, the investment has reached a colossal amount of Rs 136,147 crores during the Eleventh Plan period.

### EVALUATION OF FAMILY PLANNING

Evaluation is defined as a “process of making judgements about selected objectives and events by comparing them with specified value standards for the purpose of deciding alternative course of action”. The purpose of evaluation is to improve the design and delivery of family planning services.

Five types of evaluation have been defined by a WHO Expert Committee in 1975 (30) on evaluation of family planning in health services:

1. Evaluation of need
   - That is, health, demographic and socio-economic needs for family planning. For example, the current status of maternal mortality in a given area is an indicator of the need for family planning.

2. Evaluation of plans
   - That is, assessment of the feasibility and adequacy of programme plans.

3. Evaluation of performance
   - (a) Services: Clinic services, mobile services, post-partum services, contraceptive distribution, follow up services, education and motivation activities.
   - (b) Response: Number of new acceptors, characteristics of acceptors.
4. Evaluation of effects
Changes in knowledge, attitudes, motivation and behaviour.

5. Evaluation of impact
A WHO Study Group in 1976 (122) proposed the following indices for evaluating the impact: (a) Family size (census of living children); (b) desired number of additional children; (c) birth interval (d) age of the mother at birth of first child and last child (e) birth order, and (f) number of abortions. To this may be added, changes in birth rate and growth rate.

Evaluation is a technical activity that requires trained personnel, statistical facilities and adequate flow of data and information.

The Family Welfare Programme in India has come a long way and holds forth the promise that in the not very distant future it may be accepted as a way of life by most people. Although birth control continues to occupy the same important position in the programme as it used to be in the earlier days the programme now aims at achieving a higher end — and that is, to improve, in conjunction with other development programmes, the quality of life of the people (121).

17. TARA Services Ltd. (2006), Statistical Outline of India 2005-06.
In any community, mothers and children constitute a prider group than any other. In sheer numbers, they comprise approximately 71.14 per cent of the population of the developing countries. In India, women of the child-bearing age (15 to 44 years) constitute 22.2 per cent, and children under 15 years of age about 35.3 per cent of the total population. Together they constitute nearly 57.5 per cent of the total population. By virtue of their numbers, mothers and children are the major consumers of health services, of whatever form.

Mothers and children not only constitute a large group, but they are also a "vulnerable" or special-risk group. The risk is connected with child-bearing in the case of women; and growth, development and survival in the case of infants and children. Whereas 50 per cent of all deaths in the developed world are occurring among people over 70, the same proportion of deaths are occurring among children during the first five years of life in the developing world. Global observations show that in developed regions maternal mortality ratio averages at 16 per 100,000 live births; in developing regions the figure is 440 for the same number of live births (1). From commonly accepted indices, it is evident that infant, child and maternal mortality rates are high in many developing countries. Further, much of the sickness and deaths among mothers and children is largely preventable. By improving the health of mothers and children, we contribute to the health of the general population. These considerations have led to the formulation of special health services for mothers and children (2).

The problems affecting the health of mother and child are multifactorial. Despite current efforts, the health of mother and child still constitutes one of the most serious health problems affecting the community, particularly in the developing countries. The present strategy is to provide mother and child health services as an integrated package of "essential health care", also known as primary health care which is based on the principles of equity, intersectoral coordination and community participation. The primary health care approach combines all elements in the local community necessary to make a positive impact on the health status of the population, including the health of mothers and children.

**Mother and child – one unit**

Mother and child must be considered as one unit. It is because: (1) during the antenatal period, the foetus is part of the mother. The period of development of foetus in mother is about 280 days. During this period, the foetus obtains all the building materials and oxygen from the mother's blood; (2) child health is closely related to maternal health. A healthy mother brings forth a healthy baby; there is less chance for a premature birth, stillbirth or abortion; (3) certain diseases and conditions of the mother during pregnancy (e.g., syphilis, German measles, drug intake) are likely to have their effects upon the foetus; (4) after birth, the child is dependent upon the mother. At least up to the age of 6 to 9 months, the child is completely dependent on the mother for feeding. The mental and social development of the child is also dependent upon the mother. If the mother dies, the child's growth and development are affected (maternal deprivation syndrome); (5) in the care cycle of women, there are few occasions when service to the child is not simultaneously called for. For instance, postpartum care is inseparable from neonatal care and family planning advice; (6) the mother is also the first teacher of the child. It is for these reasons, the mother and child are treated as one unit.

**Obstetrics, Paediatrics and Preventive and Social Medicine**

In the past, maternal and child health services were rather fragmented, and provided piecemeal "personal health services" by different agencies in different ways and in separate clinics. The current trend in many countries is to provide integrated MCH and family planning services as compact family welfare service. This implies a close relationship of maternity health to child health, of maternal and child health to the health of the family; and of family health to the general health of the community. In providing these services, specialists in obstetrics and child health (paediatrics) have joined hands, and are now looking beyond the four walls of hospitals into the community to meet the health needs of mothers and children aimed at positive health. In the process, they have linked themselves to preventive and social medicine, and as a result, terms such as "social obstetrics", "preventive paediatrics" and "social paediatrics" have come into vogue.

**OBSTETRICS**

Obstetrics is largely preventive medicine. The aim of obstetrics and preventive medicine is the same, viz. to ensure that throughout pregnancy and puerperium, the mother will have good health and that every pregnancy may
cullminate in a healthy mother and a healthy baby. The age- 
old concept that obstetrics is only antenatal, intranatal and 
postnatal care, and is thus concerned mainly with technical 
skills, is now considered as a very narrow concept, and is 
being replaced by the concept of community obstetrics 
which combines obstetrical concerns with concepts of 
primary health care.

SOCIAL OBSTETRICS

The concept of social obstetrics has gained currency in 
recent years, it may be defined as the study of the 
interaction of social and environmental factors and human 
reproduction going back to the preconceptional or even 
prenatal period. The social and environmental factors 
which influence human reproduction are legion, viz. age at 
marrige, child bearing, child spacing, family size fertility 
pattern, level of education, economic status, customs and 
beliefs, role of women in society, etc. A study of these factors 
is an important aspect of social obstetrics. The social 
obstetric problems in India, differ from the social obstetric 
problems in the developed countries, because of various 
differing social, economic, cultural and other factors. While 
accepting the influence of environmental and social factors 
on human reproduction, social obstetrics has yet another 
dimension, that is the influence of these factors on the 
organization, delivery and utilization of obstetric services by 
the community. In other words, social obstetrics is 
concerned with the delivery of comprehensive matrnity and 
child health care services including family planning so 
that they can be brought within the reach of the total 
community.

Preventive paediatrics

Paediatrics which is synonymous with child health is that 
branch of medical science that deals with the care of 
children from conception to adolescence, in health and 
disease. Paediatrics is the first clinical subjects to link 
itself to preventive medicine. Like obstetrics, paediatrics 
has a large component of preventive and social medicine. 
There is no other discipline so comprehensive as paediatrics 
that teaches the value of preventive medicine. Recent 
years have witnessed further specialization within the broad 
field of paediatrics viz. preventive paediatrics, 
social paediatrics, neonatology, perinatology, developmental 
paediatrics, paediatric surgery, paediatric neurology, and 
so on.

Preventive paediatrics comprises efforts to avert rather 
than cure disease and disabilities. It has been broadly 
divided into antenatal paediatrics and postnatal paediatrics. 
The aims of preventive paediatrics and preventive medicine 
are the same: prevention of disease and promotion of 
physical, mental and social well-being of children so that 
each child may achieve the genetic potential with which he/ 
she is born. To achieve these aims, hospitals for children 
have adopted the strategy of "primary health care" to 
Improve child health care through such activities as growth 
monitoring, oral rehydration, nutritional surveillance, 
promotion of breast-feeding, immunization, community 
feeding, regular health check-ups, etc. Primary health care 
with its potential for vastly increased coverage through an 
integrated system of service delivery is increasingly looked 
upon as the best solution to reach millions of children, 
especially those who are most in need of preventive and 
care services.

Social paediatrics

The challenge of the time is to study child health in 
relation to community, to social values and to social policy. 
This has given rise to the concept of social paediatrics. Social 
paediatrics has been defined as "the application of the 
principles of social medicine to paediatrics to obtain a 
more complete understanding of the problems of children in 
order to prevent and treat disease and promote their 
adequate growth and development, through an organized 
health structure (3)." Social paediatrics, like social 
obstetrics, covers a wide responsibility. It is concerned not 
only with the social factors which influence child health but 
also with the influence of these factors on the organization, 
delivery and utilization of child health care services. In other 
words, social paediatrics is concerned with the delivery of 
comprehensive and continuous child health care services and 
to bring these services within the reach of the total 
community. Social paediatrics also covers the various social 
welfare measures - local, national and international - aimed 
to meet the total health needs of a child.

Preventive and social medicine, with its involvement in 
total community care, and expertise in epidemiology and in 
the methodology of collection and utilization of data relating 
to the community and the environment, makes an 
dispensable contribution to social obstetrics and social 
paediatrics in the : 

1. collection and interpretation of community statistics, 
   delineating groups at risk for special care; 
2. correlation of vital statistics (e.g. maternal and infant 
   mortality rates, perinatal and child mortality rates) with social and biological 
   characteristics such as birth weight, parity, age, 
   stature, employment etc. in the elucidation of 
   aetiological relationships; 
3. study of cultural patterns, beliefs and practices relating 
   to childbearing and childrearing, knowledge of which 
   might be useful in promoting acceptance and 
   utilization of obstetric and paediatric services by the 
   community; 
4. to determine priorities and contribute to the planning 
   of MCH services and programmes, and 
5. to determine whether MCH services and programmes are accomplishing their objectives in terms of their 
   effectiveness and efficiency.

Hitherto, obstetrics, paediatrics and preventive and social 
medicine were operating in wattertigh compartments. The 
emergence of social paediatrics, social obstetrics and their 
association with preventive and social medicine are certainly 
new developments in contemporary medicine. In some 
Universities, a chair of social paediatrics has also been 
established. The increasing coming together of these 
disciplines augurs well for the provision of comprehensive 
mother and child health care and family planning services as 
compact family welfare services.

Maternity cycle

The stages in maternity cycle are :

(i) Fertilization
(ii) Antenatal or prenatal period
(iii) Infranatal period
(iv) Postnatal period
(v) Infu-conceptional period.
Fertilization takes place in the outer part of the fallopian tube. Segmentation of the fertilized ovum begins at once and proceeds at a rapid rate. The fertilized ovum reaches the uterus in 8 to 10 days. Cell division proceeds at a rapid rate. By a process of cell division and differentiation, all the organs and tissues of the body are formed. The periods of growth have been divided as follows:

1. Prenatal period:
   (a) Ovum = 0 to 14 days
   (b) Embryo = 14 days to 9 weeks
   (c) Foetus = 9th week to birth

2. Premature infant = from 28 to 37 weeks

3. Birth, full term = average 280 days.

MCH problems

MCH problems cover a broad spectrum. At one extreme, the most advanced countries are concerned with problems such as perinatal problems, congenital malformations, genetic and certain behavioural problems. At the other extreme, in developing countries, the primary concern is reduction of maternal and child mortality and morbidity, spacing of pregnancies, limitation of family size, prevention of communicable diseases, improvement of nutrition and promoting acceptance of health practices. Currently, the main health problems affecting the health of the mother and the child in India, as in other developing countries, revolve around the triad of malnutrition, infection and the consequences of unregulated fertility (4). Associated with these problems is the scarcity of health and other social services in vast areas of the country together with poor social and economic conditions.

1. MALNUTRITION

Malnutrition is like an iceberg: most people in the developing countries live under the burden of malnutrition. Pregnant women, nursing mothers and children are particularly vulnerable to the effects of malnutrition. The adverse effects of maternal malnutrition have been well documented—maternal depletion, low birth weight, anaemia, toxemias of pregnancy, postpartum haemorrhage, and leading to high mortality and morbidity. The effects of malnutrition are also frequently more serious during the formative years of life. Previously it was thought that malnutrition was largely concentrated in school age children, and in toddlers. Now it is realized that the *intrauterine period* of life is a very important period from the nutritional standpoint. Infants born with adequate birth weight have relatively low mortality even under poor environmental conditions. The next critical period of childhood is the period of weaning. Severe malnutrition coincides with the age at which babies are usually weaned. Susceptibility to infection and severity of illness are significantly low in well nourished, than in malnourished children. Nutrition protection and promotion is, therefore, an essential activity of MCH care.

Measures to improve the nutritional status of mothers and children may be broadly divided into direct and indirect nutrition interventions (4). *Direct* interventions cover a wide range of activities, viz., supplementary feeding programmes, distribution of iron and folic acid tablets, fortification and enrichment of foods, nutrition education, etc. *Indirect* nutrition interventions have still wider ramifications because they are not specifically related to nutrition. These include measures such as control of communicable diseases through immunization, improvement of environmental sanitation, provision of clean drinking water, family planning, food security, education and job opportunities. While direct surveillance is becoming increasingly important for identifying subclinical malnutrition, as it tends to be overlooked in both the mother and the child. The primary health worker (community worker) can play a vital role in improving the nutritional status of mothers and children.

2. INFECTION

Maternal infections may cause a variety of adverse effects such as foetal growth retardation, low birth weight, embaphasia, abortion and perinatal sepsis. In industrial societies, the risk of the mother acquiring infections during pregnancy is relatively low, but in underdeveloped areas, the mother is exposed to significantly higher risks. Many women are infected with HIV, hepatitis B, cytomegalovirus, herpes simplex virus or toxoplasma during pregnancy. Furthermore, as many as 25 percent of the women in rural areas suffer at least one bout of urinary infection (5).

As far as the baby is concerned, infection may begin with labour and delivery and increase as the child grows older. Children may be ill with debilitating diarrhoeal, respiratory and skin infections for as much as a third of their first year of life. In some regions, the situation is further aggravated by such chronic infections as malaria and tuberculosis. The occurrence of multiple and frequent infections may precipitate in the children a severe protein-energy malnutrition and anaemia. When the child becomes ill, traditional beliefs and taboos enter into play; the indirect effect of infections may be more important than the direct one in traditional societies (5, 6).

Prevention and treatment of infections in mother and children is a major and important part of normal MCH care activity. It is now widely recognized that children in developing areas need to be immunized against six infections—tuberculosis, diphtheria, whooping cough, tetanus, measles and polo. Many countries, including India, have adopted the WHO Expanded Programme on Immunization as part of everyday MCH care. Tetanus toxoid application during pregnancy has also been taken up. Education of mothers in medical measures such as oral rehydration in diarrhoea and febrile diseases is being tried. In addition, a good knowledge and practice of personal hygiene and appropriate sanitation measures, particularly in and around the home, are essential pre-requisites for the control of the most common infectious and parasitic diseases.

3. UNCONTROLLED REPRODUCTION

The health hazards for the mother and the child resulting from unregulated fertility have been well recognized—increased prevalence of low birth weight babies, severe anaemia, abortion, antepartum haemorrhage and a high maternal and perinatal mortality, which have shown a sharp rise after the 4th pregnancy. Statistics have shown that it is almost every country in the world, a high birth rate is associated with a high infant mortality rate and under-five death rate (Table 1).

Source: (7)

Because family planning has a striking impact on the health of the mother and the child, a number of countries have integrated family planning in the MCH care activities. The introduction of new types of IUD, easier and safer techniques of pregnancy terminations and female sterilization; oral pills and long-acting injectable medroxyprogesterone acetate (MPA) have contributed a good deal in the utilization of family planning services. In some countries, MCH programmes are extending their scope to include family-life education in schools. There is also an increasing acceptance of the role of traditional midwives and community health workers, with suitable training for the extension of family planning services to remote rural areas.

Maternal and child health

The term "maternal and child health" refers to the promotive, preventive, curative and rehabilitative health care for mothers and children. It includes the sub-areas of maternal health, child health, family planning, school health, handicapped children, adolescence, and health aspects of care of children in special settings such as day care (4).

The specific objectives of MCH are (a) reduction of maternal, perinatal, infant and childhood mortality and morbidity; (b) promotion of reproductive health; and (c) promotion of the physical and psychological development of the child and adolescent within the family. The ultimate objective of MCH services is lifelong health (4).

Pregnancy detection

The simple way to confirm pregnancy in the first trimester is to conduct a urine examination using a pregnancy test kit. The kit detects pregnancy on the basis of presence of human chorionic gonadotrophin hormone in the urine. The test is performed soon after a missed period and is simple to perform. The pregnancy test should be offered to any women who is in reproductive age group and comes with a history of amenorrhoea or symptoms of pregnancy. The Government of India has made "Pinchay" pregnancy test kit available across the country. Other test kits are also available in the market. The kit is provided to ASHA or other link workers and the women should be advised appropriately on the result of the test (8).

ANTENATAL CARE

Antenatal care is the care of the woman during pregnancy. The primary aim of antenatal care is to achieve at the end of a pregnancy a healthy mother and a healthy baby. Ideally this care should begin soon after conception and continue throughout pregnancy. In some countries, notification of pregnancy is required to bring the mother in the prevention care cycle as early as possible.

Objectives

The objectives of antenatal care are:

1. To promote, protect and maintain the health of the mother during pregnancy.
2. To detect "high-risk" cases and give them special attention.
3. To detect complications and prevent them.
4. To remove anxiety and dread associated with delivery.
5. To reduce maternal and infant mortality and morbidity.
6. To teach the mother elements of child care, nutrition, personal hygiene, and environmental sanitation.
7. To sensitize the mother to the need for family planning, including advice to cases seeking medical termination of pregnancy; and
8. To attend to the under-fives accompanying the mother.

The above objectives are achieved by the following programme of health care services:

(1) Antenatal visits

Ideally the mother should attend the antenatal clinic once a month during the first 7 months; twice a month, during the next month; and thereafter, once a week, if everything is normal. A high proportion of mothers in India are from lower socio-economic group, and many of them are working women. Attendance at the antenatal clinic may mean loss of daily wages. Consequently, it is difficult for them to attend the antenatal clinic so often. In these cases, a minimum of 4 visits covering the entire period of pregnancy should be the target.

The suggested schedule is as follows (8):

1st visit – within 12 weeks, preferably as soon as the pregnancy is suspected, for registration of pregnancy and first antenatal check-up.
2nd visit – between 14 and 26 weeks
3rd visit – between 28 and 34 weeks.
4th visit – between 36 weeks and term.

It is advisable for the woman to visit medical officer at the PHC for an antenatal check-up during the period of 26-34 weeks (3rd visit). Besides this, she may be advised to avail investigation facilities at the nearest PHC/CHC/FRG.

Registration of pregnancy within 12 weeks is the primary responsibility of the ANM. Opportunities such as Village Health Nutrition Day should be availed to ensure early registration of pregnancy and antenatal check-up.

Early pregnancy detection is important for the following reasons (8):

1. It facilitates proper planning and allows for adequate care to be provided during pregnancy for both the mother and the foetus.
2. Record the date of last menstrual period and calculate the expected date of delivery.

3. The health status of the mother can be assessed and any medical illness that she might be suffering from can be detected. Also, co-obtain and record the baseline information on blood pressure, weight, haemoglobin etc.

4. It helps in timely detection of complications at an early stage and helps to manage them appropriately by referring and where required.

5. It also helps to confirm if the pregnancy is wanted and if not, refer the woman at the earliest to a 24-hour PHC or FRU that provides safe abortion services. The health personnel should be alert to the possibility of sex-selective abortion as such abortions are illegal.

6. Early detection of pregnancy and provision of care from the initial stage facilitates a good inter-personal relationship between the care giver and the pregnant woman.

**Estimation of number of pregnancies in a specified area and pregnancy tracking (8)**

To ensure complete registration, it is essential that the ANM should know the estimated number of pregnancies to be registered annually in her area. Calculating the expected number of annual pregnancies in the area will help her judge how many pregnancies registration is. In case the number of pregnancies registered is less than that of the estimated pregnancies, she needs to track down the pregnancies she has missed, with the help of ASHAs and AWWS. Estimating the number of pregnancies will also help her judge whether she has an adequate stock of the supplies required to provide routine ANC (such as TT injections, IFA tablets and ANC record forms) and tackle any complications that arise during this period.

**The number of expected pregnancies per year:**

The ANM must know the population size and birth rate of the area under her jurisdiction. The expected number of live births may be calculated as shown below:

\[
\text{Expected no. of live births} = \frac{\text{Birth rate (per 1000 population)} \times \text{area}}{\text{of the area}}
\]

(1) Where some pregnancies may not result in a live birth (i.e., abortions and stillbirths may occur), the expected number of live births would be an under-estimation of the total number of pregnancies. Hence, a correction factor of 10% is required, i.e., add 10% to the figure obtained above.

So, the total number of expected pregnancies

\[ (2) = Y + 10\% \text{ of } Y \]

As a thumb rule, in any given month, approximately half the number of pregnancies estimated above should be in records.

**Example of estimation of the number of pregnancies annually**

- **Birth rate:** 25/1000 population
- **Population under the sub-centre:** 5000

Therefore, expected number of live births = 25 × 5000/1000 = 125 births

Correction factor (pregnancy wastage) = 10% of 125 = say 13

Therefore, total no. of expected pregnancies in a year = 125 + 13 = 138

In any month, the ANM should have about 69 pregnancies registered with her.

If the number of women registered is less than expected, the ANM should approach community leaders and key people to ensure that the pregnant women are registered and come for ANC. ASHA and link worker should visit every house in the area and ensure that all pregnant women are registered. Some women may be receiving ANC from the private sector. Ensure that their names are added to the names of the facilities where they are registered.

The ANM must keep track of all pregnant women in her area. In case a registered woman does not turn up for her ANC check-up, ANM must follow her and counsel her for the regular ANC check-up. An antenatal check-up after a missed appointment should include all the components of the missed visit(s) as well as those that correspond to the present visit. For example, the woman should be given her TT injection and supply of IFA tablets, her weight and blood pressure should be checked besides being screened for complications.

A policy decision has been taken for a name-based tracking system whereby pregnant women and children can be tracked for their ANCs and immunization along with a feedback system for the ANM, ASHA etc. This has been done to ensure that all pregnant women receive their ANCs and PCNs, and children receive full immunization. This will also help in tracking and ensuring ANC/PCN for missed/late out cases.

**PREVENTIVE SERVICES FOR MOTHERS (ANTENATAL CHECK-UP)**

A. The first visit, irrespective of when it occurs, should include the following components:

I. **History-taking**

During the first visit, a detailed history of the woman needs to be taken to:

1. Confirm the pregnancy (first visit only).
2. Identify whether there were complications during any previous pregnancy confinement that may have a bearing on the present one.
3. Identify any current medical/surgical or obstetric condition(s) that may complicate the present pregnancy.
4. Record the date of 1st day of last menstrual period and calculate the expected date of delivery by adding 9 months and 7 days to the 1st day of last menstrual period.
5. Record symptoms indicating complications, e.g., fever, persisting vomiting, abnormal vaginal discharge or bleeding, palpitation, easy fatigability, breathlessness at rest or on mild exertion, generalized swelling in the body, severe headache and blurring of vision, burning in passing urine, decreased or absent bowel movements etc.
6. History of any current systemic illness, e.g., hypertension, diabetes, heart disease, tuberculosis, renal disease, epilepsy, asthma, jaundice, malaria, reproductive tract infection, STD, HIV/AIDS etc. Record family history of hypertension, diabetes, tuberculosis, and thalassaemia. Family history of twins or congenital malformation; and

II. **Physical examination**

1. **Pallor:** Presence of pallor indicates anaemia. The woman should be examined for pallor at each visit. Examine woman's conjunctiva, nails, tongue, oral mucosa and palms. Pallor should be co-related with haemoglobin estimation.
2. Pulse: The normal pulse rate is 60 to 90 beats per minute. If the pulse rate is persistently low or high, with or without other symptoms, the woman needs medical attention.

3. Respiratory rate: It is important to check the respiratory rate, especially if the woman complains of breathlessness. Normal respiratory rate is 18-20 breaths per minute.

4. Oedema: Oedema (swelling), which appears in the evening and disappears in the morning after a full night's sleep, could be a normal manifestation of pregnancy. Any oedema of the face, hands, abdominal wall and vulva is abnormal. Oedema can be suspected if a woman complains of abnormal tightness of any rings on her fingers. She must be referred immediately for further investigation. If there is oedema in association with high blood pressure, heart disease, anaemia or proteinuria, the woman should be referred to the medical officer.

5. Blood pressure: Measure the woman's blood pressure at every visit. This is important to rule out hypertensive disorders of pregnancy. Hypertension is diagnosed when two consecutive readings taken four hours or more apart show the systolic blood pressure to be 140 mmHg or more and/or the diastolic blood pressure to be 90 mmHg or more. High blood pressure during pregnancy may signify Pregnancy-Induced Hypertension (PIH) and/or chronic hypertension. If the woman has high blood pressure, check her urine for the presence of albumin. The presence of albumin (+2) together with high blood pressure is sufficient to categorize her as having preeclampsia. Refer her to the MO immediately. If the diastolic blood pressure of the woman is above 110 mmHg, it is a danger sign that points towards imminent eclampsia. The urine albumin should be estimated at the earliest. If it is strongly positive, the woman should be referred to the FRU IMMEDIATELY. If the woman has high blood pressure but no urine albumin, she should be referred to the MO at 24±7 PHC. A woman with PIH, pre-eclampsia, or imminent eclampsia requires hospitalization and supervised treatment at a 24-hour PHC/FRU.

6. Weight: A pregnant woman's weight should be taken at each visit. The weight taken during the first visit registration should be treated as the baseline weight. Normally, a woman should gain 9-11 kg during her pregnancy. Ideally, after the first trimester, a pregnant woman gains around 2 kg every month. If the diet is not adequate, i.e. if the woman is taking less than the required amount of calories, she might gain only 5-6 kg during her pregnancy. An inadequate dietary intake can be suspected if the woman gains less than 2 kg per month. She needs to be put on food supplementation. The help of the AWW should be taken in this matter, especially for those categories of women who need it the most. Low weight gain usually leads to Intrauterine Growth Retardation and results in the birth of a baby with a low birth weight. Excessive weight gain (more than 3 kg in a month) should raise suspicion of pre-eclampsia, twins (multiple pregnancy) or diabetes. Take the woman's blood pressure and test her urine for proteinuria and sugar. If the blood pressure is high and the urine is positive for protein or sugar, refer her to the medical officer.

7. Breast examination: Observe the size and shape of the nipples for the presence of inverted or flat nipples.

III. Abdominal examination

Examine the abdomen to monitor the progress of the pregnancy and foetal growth. The abdominal examination includes the following steps:

1. Measurement of fundal height: Enlargement of the uterus and the height of the uterine fundus is as shown in Fig. 1.
   a. 12 weeks - Uterine fundus just palpable per abdomen.
   b. 20 weeks - Fundus flat at the lower border of umbilicus.
   c. 36 weeks - Fundus felt at the level of xiphisternum.

   The duration of pregnancy should always be expressed in terms of completed weeks. In the first half of pregnancy the site of the uterus is of the greatest value in confirming the calculated duration of pregnancy.

2. Foetal heart sounds: The foetal heart sounds can be heard after 6th month. The rate varies between 120 to 140 per minute. They are usually best heard in the midline; after the 28th week, their location may change because of the position and lie of the foetus.

3. Foetal movement: Foetal movements can be felt by the examiner after 18-22nd week by gently palpating the abdomen.

4. Foetal parts: These can be felt about the 22nd week. After the 28th week, it is possible to distinguish the head, back and limbs.

5. Multiple pregnancy: This must be suspected if the uterus is larger than the estimated gestational age or palpation includes multiple foetal parts.

6. Foetal lie and presentation: Relevant only after 32 weeks of pregnancy.

7. Inspection of abdominal scar or any other relevant abdominal findings.

![Fig. 1](image) (Uterine fundal height at various stages of pregnancy (numbers indicate weeks of pregnancy).

IV. Assessment of gestation age (9)

Measurement of gestational age has changed over the time. As the dominant effect of gestational age on survival and long-term impairment has become apparent over the last 30 years, perinatal epidemiology has shifted from measuring birth weight alone to focusing on gestational age. The most accurate "gold standard" for assessment is routine early ultrasound assessment together with foetal measurements ideally in the first trimester. Gestational age
assessment based on the date of last menstrual period (LMP) was previously the most widespread method used and remains the only available method in many settings. Many countries now use "best obstetric estimate," combining ultrasound and LMP as an approach to estimate gestational age. It can have a large impact on the number of preterm births reported.

Any method using ultrasound requires skilled technicians, equipment, and for maximum accuracy, first trimester antenatal clinic attendance. These are not common in low-income settings, where majority of preterm births occur. Alternative approaches to LMP in these settings include fundal height, clinical assessment of the newborn after birth or birth weight as a surrogate.

V. Laboratory Investigations
The following laboratory investigations are carried out at the facilities indicated below:

a. At the sub-centre:
   - Pregnancy detection test
   - Haemoglobin examination
   - Urine test for presence of albumin and sugar
   - Rapid malaria test.

b. At the PHC/CHC/FRU:
   - Blood group, including Rh factor
   - VDRL/RPR
   - HIV testing
   - Rapid malaria test (if unavailable at SC)
   - Blood sugar testing
   - HBsAg for hepatitis B infection.

Essential components of every antenatal check-up:
1. Take the patient's history.
2. Conduct a physical examination—measure the weight, blood pressure and respiratory rate and check for pallor and oedema.
3. Conduct abdominal palpation for foetal growth, foetal lie and auscultation of foetal heart sound according to the stage of pregnancy.
4. Carry out laboratory investigations, such as haemoglobin estimation and urine tests for sugar and proteins.

Interventions and counselling:
1. Iron and folic acid supplementation and medication as needed
2. Immunisation against tetanus
3. Group or individual instruction on nutrition, family planning, self-care, delivery and parenthood
4. Home visiting by a female health worker/trained dai
5. Referral services, where necessary
6. Inform the woman about Janani Suraksha Yojana and other incentives offered by the government.

RISK APPROACH (10)
The central purpose of antenatal care is to identify "high risk" cases (as early as possible) from a large group of antenatal mothers and arrange for them skilled care, while continuing to provide appropriate care for all mothers. These cases comprise the following:
1. Elderly primi (30 years and over)
2. Short statured primi (140 cm and below)
3. Malpresentations, viz. breech, transverse lie, etc.
4. Antepartum haemorrhage, threatened abortion
5. Pre-eclampsia and eclampsia
6. Anaemia
7. Twins, hydramnios
8. Previous still-born, intrauterine death, manual removal of placenta
9. Elderly grandmultipara
10. Prolonged pregnancy (14 days after expected date of delivery)
11. History of previous caesarean or instrumental delivery
12. Pregnancy associated with general diseases, viz. cardiovascular disease, kidney disease, diabetes, tuberculosis, liver disease, malaria, convulsions, asthma, HIV, RTI, STI, etc.
13. Treatment for infertility.
14. Three or more spontaneous consecutive abortions.

The "risk approach" is a managerial tool for improved MCH care. Its purpose is to provide better services for all, but with special attention to those who need them most. Inherent in this approach is maximum utilization of all resources, including some human resources that are not conventionally involved in such care—traditional birth attendants, community health workers, women's groups, for example. The risk strategy is expected to have far-reaching effects on the whole organization of MCH/FP services and lead to improvements in both the coverage and quality of health care, at all levels, particularly at primary health care level.

MAINTENANCE OF RECORDS
A Mother and Child Protection Card should be duly completed for every woman registered. It contains a registration number, identifying data, previous health history and main health events etc. The case record should be handed over to the woman. She should be instructed to bring the record with her during all subsequent check-ups visits and also to carry it along with her at the time of delivery. This card has been developed jointly by the Ministry of Health and Family Welfare (MOHFW) and Ministry of Women and Child Development (MOWCD) to ensure uniformity in record keeping. This will also help the service provider to know the details of previous ANCs/PNCs both for routine and emergency care. The information contained in the card should also be recorded in the antenatal register as per the Health Management Information System (HMIS) format.

HOME VISITS
Home visiting is the backbone of all MCH services. Even if the expectant mother is attending the antenatal clinic regularly, it is suggested that she must be paid at least one home visit by the Health Worker Female or Public Health Nurse. More visits are required if the delivery is planned at home. The mother is generally relaxed at home. The home visit will win her confidence. The home visit will provide an opportunity to observe the environmental and social conditions at home and also an opportunity to give prenatal advice.

(2) Prenatal advice
A major component of antenatal care is prenatal or preconception advice. The mother is more receptive to advice concerning herself and her baby at this time than at other
times. The "talking points" should cover not only, the specific problems of pregnancy and child-birth but overflow into family planning aspects

(i) DIET: Reproduction cost energy. A pregnancy in total duration consumes about 60000 kcal, over and above normal metabolic requirements. To meet this demand excess 550 kcal a day. Further, child survival is correlated with birth weight. And birth weight is correlated to the weight gain of the mother during pregnancy (8). The average, a normal healthy woman gains about 9-11 kg of weight during pregnancy. Several studies have indicated that weight gain of poor Indian women averaged 6.5 kg during pregnancy (11). Thus pregnancy imposes the need for considerable extra calorie and nutrient requirements. If maternal stores of iron are poor (as may happen after repeated pregnancies) and if enough iron is not available to the mother during pregnancy, it is possible that foetus may lay down insufficient iron stores. Such a baby may show a normal haemoglobin at birth, but will lack the stores of iron necessary for rapid growth, and increase in blood volume and muscle mass in the first year of life. Stressers in the form of malaria and other childhood infections will make the deficiency more acute, and many infants become severely anaemic during early months of life. A balanced and adequate diet is therefore, of utmost importance during pregnancy and lactation to meet the increased needs of the mother, and to prevent "nutritional stress".

(ii) PERSONAL HYGIENE: Of equal importance is advice regarding personal hygiene. (a) Personal cleanliness: The need to bathe every day and to wear clean clothes also family explained. The hair should also be kept clean and tidy. (b) Rest and sleep: 8 hours sleep, and at least 2 hours rest after mid-day meals should be advised. (c) Bowels: Constipation should be avoided by regular intake of green leafy vegetables, fruits and extra fluids. Purgatives like castor oil should be avoided to relieve constipation. (d) Exercise: Light household work is advised. (e) Manual physical labour during late pregnancy may adversely affect the foetus. (e) Smoking: Smoking should be cut down to a minimum. Expectant mothers who smoke heavily produce babies much smaller than the average – it is because nicotine has a vasocostrictor influence in the uterus and induces a degree of placental insufficiency. The adverse effects of smoking range from low birth-weight to an increased risk of perinatal death of the infant (12). Women who smoke during pregnancy give birth to babies which on average weigh 170 g less at term than the babies of non-smokers. The perinatal mortality amongst babies whose mothers smoked during pregnancy is between 10-50 per cent higher than that of non-smokers. (f) Alcohol: Evidence is mounting that alcohol can cause a range of fertility problems in women. Moderate to heavy drinkers who become pregnant have greater risk of pregnancy loss (13), and if they do not abort, their children may have various physical and mental problems (14). Heavy drinking has been associated with a fetal syndrome (FAS) which includes intra-uterine growth retardation and developmental delay. More recently, it has been shown that the consumption of even moderate amount of alcohol during pregnancy is associated with an increased risk of spontaneous abortion (15). (g) Dental care: Advice should also be given about oral hygiene. (h) Sexual intercourse: This should be restricted especially during the last trimester.

(iii) DRUGS: The use of drugs that are not absolutely essential should be discouraged. Certain drugs taken by the mother during pregnancy may affect the foetus adversely and cause foetal malformations. The classical example is thalidomide, a hypnotic drug, which caused deformed hands and feet of the babies born. The drug proved most serious when taken between 4 to 8 weeks of pregnancy. Other examples are LSD which is known to cause chromosomal damage, and some sedatives. Benzodiazepines may cause milk infertility in the foetus (16). Corticosteroids may impair foetal growth, sex hormones may produce virilism, tetracyclines may affect the growth of bones and enamel formation of teeth. Anaesthetic agents including pethidine administered during labour can have depressant effect on the baby and delay the onset of effective respiration. Later still in the peripuerium, if the mother is breast-feeding, there are certain drugs which are excreted in breast milk. A great deal of caution is required in the drug-intake by pregnant women (17).

(iv) RADIATION: Exposure to radiation is a positive danger to the developing foetus. The most common source of radiation is abdominal X-ray during pregnancy. Careful cohort studies have shown that mortality rates from leukaemia and other neoplasms were significantly greater among children exposed to intrauterine X-ray. This is in addition to congenital malformations such as microcephaly. The X-ray examination in pregnancy should be carried out only for definite indications. X-ray dosage kept to minimum. Furthermore, in all women of child-birthing age among whom there is a possibility of pregnancy, elective X-ray should be avoided in the two weeks preceding the menstrual period.

(v) WARNING SIGNS: The mother should be given clear-cut instructions that she should report immediately in case of the following warning signals: (a) swelling of the feet (b) (i) (c) (d) (e) (f) any other unusual symptoms.

(vi) CHILD CARE: The art of child care has to be learnt. Special clamps are held for mothers attending antenatal clinics. Mother-craft education consists of nutrition education, advice on hygiene and childrearing, cooking demonstrations, family planning education, family budgeting, etc.

(3) Specific health protection

(i) ANAEMIA: Surveys in different parts of India indicate that about 50 to 60 per cent of women belonging to low socio-economic groups are anaemic in the last trimester of pregnancy (11). The major aetiological factors being iron and folic acid deficiencies. It is well known that anaemia per se is associated with high incidence of premature births, postpartum haemorrhage, puerperal sepsis and thromboembolic phenomena in the mother. The Government of India has initiated a programme in which 100 mg of elemental iron, and 500 mg of folic acid are being distributed daily for 100 days to pregnant women through antenatal clinics, primary health centres and their subcentres.

(ii) OTHER NUTRITIONAL DEFICIENCIES: The mother should be protected against other nutritional deficiencies that may occur, particularly protein, vitamin and mineral especially vit A and iodine deficiency. In some MCH Centres, fresh milk is supplied free of cost to all expectant mothers, where this is not possible, skimmed milk should be given. Capsules of vitamin A and D are also supplied free of cost.

(iii) TOXEMIAS OF PREGNANCY: The presence ofalbumin in urine and an increase in blood pressure
PREVENTIVE MEDICINE IN OBSTETRICS, PAEDIATRICS AND GERIATRICS

indicates toxemias of pregnancy. Their early detection and management are indicated. Efficient antenatal care minimizes the risk of toxemias of pregnancy.

(iv) TETANUS: If the mother was not immunized earlier, 2 doses of adsorbed tetanus toxoid should be given: the first dose at 16–20 weeks and the second dose at 20–24 weeks of pregnancy. The minimum interval between the 2 doses should be one month. No pregnant woman should be denied even one dose of tetanus toxoid, if she is seen late in pregnancy. For women who have been immunized earlier, one booster dose will be sufficient. When such a booster has been given, it will provide necessary cover for subsequent pregnancies, during the next 5 years. It is advised not to inject tetanus toxoid at every successive pregnancy because of the risk of hyperimmunization and side-effects.

(v) ST. PHILLIPS: Syphilis is an important preventable cause of pregnancy wastage in some countries. Pregnancies in women with primary and secondary syphilis often end in spontaneous abortion, stillbirth, perinatal death, or the birth of a child with congenital syphilis. Syphilitic infection in the pregnant woman is transmissible to the foetus. Neurological damage with mental retardation is one of the most serious consequences of congenital syphilis. When the mother is suffering from syphilis, infection of the foetus does not occur before the 4th month of pregnancy; it is most likely to occur after the 6th month in which time the Langham’s cell layer has completely atrophied (18). Infection of the foetus is most likely to occur when the mother is suffering from primary or secondary stages of syphilis than late syphilis.

It is routine procedure in antenatal clinics to test blood for syphilis at the first visit. Since the mother can subsequently get infected with syphilis, the ideal procedure would be to test blood for syphilis both early and late in pregnancy (18). Congenital syphilis is easily preventable. Ten daily injections of penicillin (600,000 units) are almost always adequate (18).

(vi) GERMAN MEASLES: The best estimate of the total risk comes from the long-term prospective study carried out in Great Britain. When rubella was contracted in the first 16 weeks of pregnancy, foetal death or death during the first year of life occurred in the affected child 17 per cent of the pregnancies. Among survivors who were followed up to age 8 years, 15 per cent had major defects, of which cataract, deafness and congenital heart diseases were the most common. Minor defects were found in an additional 16 per cent. It appears that the risk of all degrees of malformed foetuses may remain in the region of 20 per cent up to the 20th week (19).

Ideally we should prevent infection during pregnancy by preventing and controlling the disease in the general population. In many countries, this is being attempted by vaccination of all school-aged children with rubella vaccine. This will allow the community to control the infection and vaccinate all women of childbearing age who are anti-negative. Before vaccinating, it is advisable that pregnancy be ruled out and effective contraception be maintained for 8 weeks after vaccination because of the possible risk to the foetus from the virus.

(vii) Rb STATUS: The foetal red cells may enter the maternal circulation in a number of different circumstances, during labour, caesarean section, therapeutic abortion, external cephalic version, and apparently spontaneously in the late pregnancy. The intrusions of these cells, if the mother is Rh-negative and the child is Rh-positive, provokes an immune response in her so that she forms antibodies to Rh which can cross the placenta and produce foetal haemolysis. The same response may be produced to a greater degree by a transfusion of Rh-positive blood. In a pregnant woman, immunization mainly occurs during labour, so that the tolerance to the Rh factor may be less in the subsequent pregnancies, the more so if the mother has been already sensitized. In the second or subsequent pregnancies, if the child is Rh-positive, the mother will react to it. In smaller amount of foetal cells, by producing antibodies to destroy foetal blood cells causing haemolytic disease in the foetus. Clinically haemolytic disease takes the form of hydrops foetalis, intravascular coagulation, and neonatal anaemia (of which kernicterus is often a sequel) and congenital haemolytic anaemia.

P is a routine procedure in antenatal clinics to test blood for Rh factor in early pregnancy. If the woman is Rh-negative and the husband is Rh-positive, she is kept under surveillance for determination of Rh antibody levels during antenatal care. The blood should be further examined at 28 weeks and 34–36 weeks of gestation for antibodies. Rh anti-D immunoglobulin should be given at 28 weeks of gestation so that sensitization during the first pregnancy can be prevented. If the baby is Rh-positive, the Rh anti-D immunoglobulin is given again within 72 hours of delivery. It should also be given after abortion. Post-maturity should be avoided. Whenever there’s evidence of haemolytic process in foetus in utero, the mother should be shifted to an equipped centre specialized to deal with Rh problems. The Incidence of haemolytic disease due to Rh factor in India is estimated to be approximately one for every 400 to 500 live births.

(viii) HIV INFECTION: HIV may pass from an infected mother to her foetus through the placenta or in her infant during delivery or breast-feeding. Prenatal testing for HIV infection should be done as early in pregnancy as possible for pregnant women who are at high risk (if they or their partner has a number of sexual partners; has a sexually transmitted disease; uses illicit injectable drugs etc.). Universal confidential voluntary screening of pregnant women in high-prevalence areas may allow infected women to choose therapeutic abortion, make an informed decision on breast-feeding, or receive appropriate care. Screening should not be used as a substitute for primary prevention through community-wide education on safe sexual practice, making condoms readily available and preventing penile-vaginal transmission.

(ix) HEPATITIS B INFECTION: Spread of infection from HBV carrier mothers to their babies appears to be a factor for the high prevalence of HBV infection in some regions. The mechanism of perinatal infection is uncertain. Most infections appear to occur at birth. Transmission of the virus to the baby after or even infancy is likely if both surface antigen and e antigen are positive. Vertical transmission can be blocked by immediate post-delivery administration of B immunoglobulin and hepatitis B vaccine. Please refer to page 534 for details.

(x) PRENATAL GENETIC SCREENING: Prenatal genetic screening includes screening for chromosomal abnormalities associated with serious birth defects, screening for direct evidence of congenital structural anomalies, and screening for haemoglobinopathies and other inherited conditions detectable by biochemical assay. Universal genetic screening...
is generally not recommended. Screening for chromosomal abnormalities and for direct evidence of structural anomalies is performed in pregnancy in order to make the option of therapeutic abortion available when severe defects are detected. Typical examples are screening for trisomy 21 (Down’s syndrome) and severe neural tube defects. Women aged 35 years and above, and those who already have an afflicted child are at higher risk.

(4) Mental preparation
Antenatal care does not mean only palpation, blood and urine examination and pelvic examinations. These are no doubt important aspects of antenatal care. Mental preparation is as important as physical or material preparation. Sufficient time and care are needed to be given to the expectant mothers to have a free and frank talk on all aspects of pregnancy and delivery. This will go a long way in smoothing her fears about confinement. The “mothercraft” classes at the MCH Centres help a great deal in achieving this objective.

(5) Family planning
Family planning is related to every phase of the maternity cycle. The mother is psychologically more receptive to advice on family planning than at other times. Educational and motivational efforts must be initiated during the antenatal period. If the mother has had 2 or more children, she should be motivated for proteral sterilization. In this connection, the All India Postpartum Programme services are available to all expectant mothers in India (21).

(6) Paediatric component
It is suggested that a paediatrician should be in attendance at all antenatal clinics and pay attention to the under-five accompanying the mothers.

INTRANATAL CARE
Childbirth is a normal physiological process, but complications may arise. Septicaemia may result from unskilled and septic manipulations, and tetanus neonatorum from the use of unsterilized instruments. The need for effective intranatal care is therefore indispensable, even if the delivery is going to be a normal one. The emphasis is on the cleanliness. It entails – clean hands and fingernails, a clean surface for delivery, clean cord care i.e., clean blade for cutting the cord and clean tie for the cord, no application on cord stump, and keeping birth canal clean by avoiding harmful practices. Hospitals and health centres should be equipped for delivery with midwifery kits. A regular supply of sterile gloves and gowns, towels, cleansing materials, soap and antiseptic solution, as well as equipment for sterilizing instruments and supplies. There are delivery kits available with the items needed for basic hygiene for delivery at home, where a midwife with a midwifery kit is not likely to be present. The aims of good intranatal care are:

(i) thorough asepsis
(ii) delivery with minimum injury to the infant and mother
(iii) readiness to deal with complications such as prolonged labour, antepartum haemorrhage, convulsions, malpresentations, prolapse of the cord, etc.
(iv) Care of the baby at delivery – resuscitation, care of the cord, care of the eyes, etc.

Domiciliary care
Mothers with normal obstetric history may be advised to have their confinement in their own homes, provided the home conditions are satisfactory. In such cases, the delivery may be conducted by the Health Worker Female or trained dai. This is known as “domiciliary midwifery service.”

The advantages of the domiciliary midwifery service are:
1. The mother delivers in the familiar surroundings of her home and this may tend to remove the fear associated with delivery in a hospital. (2) The chances for cross infection are generally fewer at home than in the nursery/hospital, and the mother is able to keep an eye upon her children and domestic affairs; this may tend to ease her mental tension.

Domiciliary midwifery is also not without disadvantages:
1. The mother may have less medical and nursing supervision than in the hospital, (2) the mother may have less rest, (3) she may resume her domestic duties too soon, and (4) her diet may be neglected. Strictly speaking, many homes in India are unsuitable for even a normal delivery. The argument that childbirth is a natural event and should take place at home does not guarantee that everything will be normal.

Since 72.2 per cent of India’s population live in rural areas, most deliveries will take place in the home with the aid of Female Health Workers or trained dais. Domiciliary midwifery is a major component of intranatal health care: The Female Health Worker, who is a pivot of domiciliary care, should be adequately trained to recognize the ‘danger signals’ during labour and seek immediate help in transferring the mother to the nearest Primary Health Centre or Hospital. The danger signals are:

1. sluggish pains or no pains after rupture of membranes
2. good pains for an hour after rupture of membranes, but no progress
3. geotapse of the cord or hand
4. meconium-stained liquor or a slow irregular or excessively fast foetal heart
5. excessive ‘show’ or bleeding during labour
6. frayed cord or dilated cervix
7. a placenta not separated within half an hour after delivery
8. post-partum haemorrhage or collapse, and
9. a temperature of 38.5 deg C or over during labour. These should be a close liaison between domiciliary and institutional delivery services.

Institutional care
About one per cent of deliveries tend to be abnormal, and four per cent “difficult”, requiring the services of a doctor. Institutional care is recommended for all “high-risk” cases, and where home conditions are unsuitable.

The mother is allowed to rest in bed on the first day after delivery. From the next day, she is allowed to be up and about. The current practice is to discharge the woman after 5 days lying-in period after a normal delivery.

Rooming-in
Keeping the baby’s crib by the side of the mother’s bed is called “rooming-in’. This arrangement gives an opportunity for the mother to know her baby. Mothers interested in breast feeding usually find there is a better chance for success with rooming-in. Rooming-in also allays the fear in
the mother's mind that the baby is not misplaced in the central nursery. It also builds up her self-confidence.

**POSTNATAL CARE**

Care of the mother (and the newborn) after delivery is known as postnatal or postpartum care. Broadly this care falls into two areas: care of the mother which is primarily the responsibility of the obstetrician; and care of the newborn, which is the combined responsibility of the obstetrician and paediatrician. This combined area of responsibility is also known as perinatology.

**Care of the mother**

The objectives of postnatal care are:

1. To prevent complications of the postpartal period.
2. To provide care for the rapid restoration of the mother.
3. To check adequacy of breast-feeding.
4. To provide family planning services.
5. To provide basic health education to mother and family.

**Complications of the postpartal period**

Certain complications may arise during the postpartal period which should be recognized early and dealt with promptly. These are: (1) **Puerperal sepsis**: This is infection of the genital tract within 3 weeks after delivery. This is accompanied by rise in temperature and pulse rate, foul-smelling lochia, pain and tenderness in lower abdomen, etc. Puerperal sepsis can be prevented by attention to asepsis before and after delivery. This is particularly important in domiciliary maternity service. (2) **Thrombophlebitis**: This is an infection of the veins of the legs, frequently associated with varicose veins. The leg may become tender, pale and swollen. (3) **Secondary haemorrhage**: Bleeding from vagina anytime from 6 hours after delivery to the end of the puerperium (6 weeks) is called secondary haemorrhage, and may be due to retained placenta or membranes. (4) **Others**: Urinary tract infection and mastitis, etc. It is extremely important to look for these complications in the postpartal period and prevent or treat them promptly.

**Restoration of mother to optimum health**

The second objective of postnatal care is to provide care to whereby the woman can recuperate physically and emotionally from her experience of delivery. The broad areas of this care fall into three divisions:

**PHYSICAL**

1. **Postnatal examinations**: Soon after delivery, the health check-ups must be frequent, i.e., twice a day during the first 3 days, and subsequently once a day till the umbilical cord drops off. At each of these examinations, the FHW checks temperature, pulse and respiration, examines the breasts, checks progress of normal involution of uterus, examines choicxa for any abnormality, checks urinary and bowel functions and advises on perineal toilet including care of the stitches, if any. The immediate postnatal complications, viz., puerperal sepsis, thrombophlebitis, secondary haemorrhage should be kept in mind. At the end of 6 weeks, an examination is necessary to check-up involution of uterus which should be complete by then. Further visits should be done once a month during the first 6 months, and thereafter once in 2 or 3 months till the end of one year. In rural areas only limited postnatal care is possible. Efforts should be made by the FHW to give at least 3 to 6 postnatal visits. The common conditions found on examination during the late postnatal period are subinvolution of uterus, retroverted uterus, prolapse of uterus and cervicitis. Postnatal examination offers an opportunity to detect and correct these defects.

2. **Anaemia**: Routine haemoglobin examination should be done during postnatal visits, and when anaemia is discovered, it should be treated. In some cases, it may be necessary to continue treatment for a year or more.

3. **Nutrition**: Though a malnourished mother is able to secrete as much breast milk as a well-nourished one, she does it at the cost of her own health. The nutritional needs of the mother must be adequately met. Often the family's budget is limited; the mother should be shown the means how she can eat better with less money.

4. **Postnatal exercises**: Postnatal exercises are necessary to bring the stretched abdominal and pelvic muscles back to normal as quickly as possible. Gradual resumption of normal household duties may be enough to restore one's figure.

**PSYCHOLOGICAL**: The next big area of postnatal care involves a consideration of the psychological factors peculiar to the recently delivered woman. One of the psychological problems is fear which is generally born of ignorance. Other problems are timidity and insecurity regarding the baby. If a woman is to endure cheerfully the emotional stresses of childbirth, she needs the support and companionship of her husband. Fear and insecurity may be eliminated by proper prenatal instruction. The so-called 'morning sickness' is perhaps precipitated by birth; and it is rather uncommon.

**SOCIAL**: It has been said that the most important thing a woman can do is to have a baby. This is only part of the truth. The really important thing is to nurture and raise the child in a wholesome family atmosphere. She, with her husband, must develop her own methods.

**Breast-feeding**

Postnatal care offers an excellent opportunity to find out how the mother is getting along with her baby, particularly with regard to feeding. For many children, breast milk provides the main source of nourishment in the first year of life. In some societies, lactation continues to make an important contribution to the child's nutrition for 18 months or longer. In the world's more affluent societies, breast-feeding appears to have become a lost art and the feeding bottle has usurped the breast. When the standard of environmental sanitation is poor and education low, the content of the feeding bottle is likely to be as nutritionally poor as it is bacteriologically dangerous. It is therefore very important to advise the mothers to avoid the feeding bottle.

A great asset in India is that an average Indian mother, although poor in nutritional status, has a remarkable ability to breast-feed her infant for prolonged periods, sometimes extending to nearly 2 years and beyond. Longitudinal and cross-sectional studies indicate that poor Indian women should be supplemented by additional foods rich in protein and other nutrients (e.g., animal milk, soft-cooked mashed vegetables, etc.). These are called supplementary foods which should be introduced very gradually in small amounts.

Family planning

It has already been stressed that family planning is related to every phase of maternity cycle. Every attempt should be made to motivate mothers when they attend postnatal clinics or during postnatal contacts to adopt a suitable method for spacing the next birth or for limiting the family size as the case may be. Postpartum, sterilization is generally recommended on the 2nd day after delivery. Although lactation confers some protection against conception, it cannot be depended upon; contraceptives have to be supplied immediately postpartum. To ask the mother to come at the time of her first menstruation may be too late. A contraceptive must therefore be used, that will not affect lactation in the early postpartum period. In this connection, IUD and conventional (non-hormonal) contraceptives are the choices during the first 6 months following delivery. In general, combined or sequential oral "pills" should be avoided in a lactating mother as they do suppress lactation. Fortunately, evidence is accumulating that progestogens alone have little or no effect on lactation. The injection of medroxy-progesterone acetate (MPA) after delivery has been found to be successful in ensuring spacing of pregnancy without suppressing lactation; however, because of its side-effects (e.g., irregular uterine bleeding, prolonged infertility) some countries have limited its use to multiparas at ages ≥35 and/or who have already completed their families. MPA is not recommended for general use.

Basic health education

Health education during the postnatal period should cover the following broad areas: (a) hygiene – personal and environmental (b) feeding for mother and infant (c) pregnancy spacing (d) importance of health check-up, and (e) birth registration.

CARE OF CHILDREN

This section focuses on children in the age group 0–14 years. This is the most important age group in all societies, not because they constitute about 40 per cent of the total population, but because there is a renewed awareness that the determinants of chronic disease in later life and health behaviour are laid down at this stage (22). Family influences and education are of the highest importance, and these experiences ultimately influence patterns of their future life-styles, occupational skills, and even political attitudes and leadership. The childhood period is also a vital period because of the so-called socialization process, that is, transmission of attitudes, customs and behaviour. In addition, of course, they are vulnerable to disease, death and disability owing to their age, sex, place of living, socio-economic class and a host of other variables. Certain specific biological and psychological needs must be met to ensure the survival and healthy development of the child and future adult.

It is customary to divide the childhood into the following age-periods:

1. Infancy (up to 1 year of age)
   a. Neonatal period (first 28 days of life)
   b. Post neonatal period (28th day to 1 year)
2. Pre-school age (1–4 years)
3. School age (5–14 years)

Antenatal paediatrics

Fifty years ago, the main purpose of antenatal care was the prevention of maternal mortality. With the fall in the maternal mortality to about 0.2 per 1000 live births, attention has shifted to the child – first to decrease perinatal mortality, secondly to prevent perinatal morbidity, and more recently to the “fetus at risk”. This has given rise to the concept of antenatal paediatrics. Recent technical developments such as amniocentesis, ultrasonography, foetoscopy and chorion biopsy have contributed significantly to the diagnosis of congenital abnormalities and inborn errors of metabolism (23, 24). This knowledge has led to the recognition that causation and possible prevention may lie in intra-uterine life. The emphasis has greatly changed in the care of the child with the prevention of disorders (e.g., low birth weight, foetal disorders and neonatal asphyxia) assuming greater importance.

Antenatal care should, appropriately, begin even before the mother conceives and enters the maternity cycle; this care comprising such measures as genetic counselling for prospective parents; limitation and proper spacing of births with intervals of 2–3 years; delaying a young woman’s first pregnancy until she is physically and socially mature enough to cope; ensuring adequate maternal nutrition; protection of the unborn against intrauterine infections and other adverse influences. In a developing country such as India, all this may not be possible, but certainly some elements, such as improvement of maternal nutrition, family planning and counselling could go a long way in ensuring maternal and foetal health.

INFANCY

Infants (0–1 year) constitute about 2.92 per cent of the total population in India. Of the 136 million children born each year in the world, 90 per cent are in the third world. Although the chances of survival of these newborns has improved by 50 per cent in the last 20 years, the first few hours, days and months of their lives are still an obstacle race. From the time of birth, 20–30 per cent of babies are under-weight. That makes them vulnerable to infection and disease. About 40 per cent of total infant mortality occurs in the first month of life. Then comes the weaning period, when one out of four surviving children receives neither the quality nor the quantity of food needed to replace the substances provided by mother’s milk. The result is that more and more children in developing countries reach adulthood with their health already largely impaired. An infant mortality rate of
NEONATAL CARE

A flow chart of the optimum care of the newborn is as shown in Fig. 2. This aspect of family health services has been termed neonatology. This branch of medicine is, perhaps, more than any other, dependent on teamwork in which disciplines of obstetrics and gynaecology, paediatrics, preventive and social medicine, community health services and nursing have an important part to play, if any impact is to be made on the vast problems of perinatal and neonatal mortality and morbidity. The paediatrician has a key role as a coordinator and guide for the whole team.

Early neonatal care

The first week of life is the most crucial period in the life of an infant. In India, 63.7 per cent of all infant deaths occur within the first month of life. Of these, more than half may die during the first week of life. This is because the newborn has to adapt itself rapidly and successfully to an alien external environment. The risk of death is the greatest during the first 24–48 hours after birth. The problem is more acute in rural areas where obstetric care is scarce, and the home environmental conditions in which the baby is born, are usually unsatisfactory.

The objective of early neonatal care is to assist the newborn in the process of adoption to an alien environment, which involves:

(i) Establishment and maintenance of cardio-respiratory functions
(ii) Maintenance of body temperature
(iii) Avoidance of infection
(iv) Establishment of satisfactory feeding regimen, and
(v) Early detection and treatment of congenital and acquired disorders, especially infections.

Congenital infections caused by toxoplasmosis, rubella, human (alpha) herpes-virus 1 or 2, human (beta) herpes virus, and syphilis (TORCHES synonyms) is associated with high mortality rate in the neonates (25).

Immediate care

1. CLEARING THE AIRWAY

Establishment and maintenance of cardio-respiratory functions (e.g., breathing) is the most important thing the moment the baby is born, and everything else is secondary. To help establish breathing, the airways should be cleared of mucus and other secretions. Positioning the baby with its head low may help in the drainage of secretions. This process can be assisted by gentle suction to remove mucus and amniotic fluid. Resuscitation becomes necessary if natural breathing fails to establish within a minute, as in the case of babies who have already been subject to hypoxia during labour. In these cases, resuscitation may require more active measures such as suction, application of oxygen mask, intubation and assisted respiration. All labour wards should be equipped with resuscitation equipment including oxygen. If the heart has stopped beating for 5 minutes, the baby is probably dead.

2. Apgar SCORE

The Apgar score is taken at 1 minute and again at 5 minutes after birth. Today it is considered as negligence to omit Apgar scoring of a newborn infant, especially low birth weight babies (56). It requires immediate and careful observation of the heart rate, respiration, muscle tone, reflex response and colour of the infant. Each sign is given a score of 0, 1 or 2 (Table 3). It provides an immediate estimate of the physical condition of the baby. A perfect score should be 9 or 10; 0–3 indicates that the baby is severely depressed and 4–6 moderately depressed. A score below 5 needs prompt action. Infants with low Apgar scores at 5 minutes of age are subject to a high-risk of complications and death during the neonatal period (25).

![Flow chart of optimum newborn care](https://example.com/flowchart.png)
3. CARE OF THE CORD

In the case of the normal infant, the umbilical cord should be cut and tied when it has stopped pulsating. The advantage is that the baby derives about 10 ml of extra blood, if the cord is cut after pulsation ceases. This is particularly important in India, where anaemia is frequent. Care must be taken to prevent tetanus of the newborn by using properly sterilized instruments and cord ties. It is essential to apply an antiseptic preparation on the cord stump and the skin around the base. The cord should be kept as dry as possible, it dries and shrivels up and separates by aseptic necrosis in 5-8 days.

4. CARE OF THE EYES

Before the eyes are open, the lid margins of the newborn should be cleaned with sterile wet swabs, one for each eye from inner to outer side. Instil a drop of freshly prepared silver nitrate solution (1 per cent) to prevent gonococcal conjunctivitis, alternatively, a single application of tetracycline 1 per cent ointment can be given. Any discharge from the eye of an infant is pathological and calls for immediate treatment.

Ophthalmia Neoratorum: A variety of organisms are implicated — N. gonorrhoea, C. trachomatis (commonest), staphylococci, streptococci, Candida spp, etc. The most serious cause of conjunctivitis of the newborn is infection with N. gonorrhoea as it can rapidly cause blindness. C. trachomatis is also an important cause of neonatal conjunctivitis. Since gonococcal ophthalmia neonatorum has become much less frequent than conjunctivitis due to other acquired organisms, application of topical neomycin might be more useful (27).

As a preventive measure, specific maternal genital tract infection should be treated effectively prior to, or during, pregnancy, and specific care should be taken while conducting forceps or breech delivery.

5. CARE OF THE SKIN

When a baby is a few hours old, the first bath is given with soap and warm water to remove vernix, meconium and blood clots. Some prefer to apply warm oil before the bath. The first bathing is done by the nursing staff. Thereafter no further bathing is necessary until the day before discharge. If culturally acceptable, the first bathing may be delayed for 12-24 hours after birth to avoid cooling the body temperature (28).

6. MAINTENANCE OF BODY TEMPERATURE

The normal body temperature of a newborn is between 36.5 to 37.5°C. A newborn baby is projected out of warm womb of the mother into an environment which may be 10 to 20°C cooler especially in winter months in India. A newborn has little thermal control and can lose body heat quickly. Immediately after birth, most of the heat loss occurs through evaporation of the amniotic fluid from the body of the wet child. As much as 75 per cent of the heat loss can occur from the head. It is important that immediately after birth the child is quickly dried with a clean cloth and wrapped in warm cloth and given to the mother for skin-to-skin contact and breast-feeding. Practices such as separating the baby from the mother for the first 12-24 hours of life are harmful. Pre-term and low birth weight babies lose heat more easily through their thin skin as they have less sub-cutaneous fat for insulation. Putting the newborn on a cold surface such as metallic tray, rubber sheeting or weighing scale should be avoided, and the child should be kept away from cold walls, open windows and from draught (29).

7. BREAST-FEEDING

Breast-feeding should be initiated within an hour of birth instead of waiting several hours as is often customary. Although there is little milk at that time, it helps to establish feeding and a close mother-child relationship, known as "bonding".

The first milk which is called "colostrum" is the most suitable food for the baby during this early period because it contains a high concentration of protein and other nutrients the body needs; it is also rich in anti-infective factors which protect the baby against respiratory infections and diarrhoeal diseases. Supplementary feeds are not necessary. The regular milk comes on the third to sixth day after birth. The baby should be allowed to breast-feed whenever it wants. Feeding the baby on demand helps the baby to gain weight. It is very important to advise mother to avoid feeding bottles.

Neonatal examinations

a. FIRST EXAMINATION

The first examination is made soon after birth, and preferably in the delivery room. This examination is (a) to ascertain that the baby has not suffered injuries during the birth process; (b) to detect malformations especially those requiring urgent treatment; and (c) to assess maturity. The following abnormalities should be looked for on routine examination:

- Maldevelopments or malformations of any organ system (e.g., cleft palate, craniofacial abnormalities, etc.).
- Congenital anomalies such as clubfoot, congenital heart defects, etc.
- Signs of cerebral palsy such as twitching, convulsions, neck rigidity, bulging of anterior fontanelle, etc.
- decreased or absent tone.

b. SECOND EXAMINATION

The second examination should be made preferably by a paediatrician within 24 hours after birth. This examination should form the first stage of a continual process of health care surveillance. It is a detailed systematic examination from head to foot, conducted in good light. The following protocol will be found useful for such an examination (30).

1. Body size
- Body weight: crown-heel length, head and thoracic perimeter.
2. Body temperature
3. Skin:
Observe for cyanosis of lips and skin; jaundice; pallor; generalized erythema; vesicular and bullous lesions.

4. Cardio-respiratory activities:
Cardiac murmurs; absence of femoral pulse; central cyanosis around 20 percent rate of over 60 per minute; thoracic cage retraction on inspiration.

5. Neuro-behavioral activity:
(i) Rupture: neck retraction; frog-like posture; hyper-extension of all limbs; hyperflexion of all limbs; asymmetrical posture
(ii) Muscle tone: hypotonia; obesity; movements.

6. Head and face:
Hydrocephalus; large fontanelles; prominent scalp vein (i) Eyes: cataact; coloboma; conjunctivitis
(ii) Ears: dysmorphism; accessory auricles; preauricular pits (iii) Mouth and lips: Hawe lip; cleft palate.

7. Abdomen:
Signs of distension; abnormal taseses; imperforate anus.

8. Limbs and joints:
Deformities of joints; congenital dislocation of the hips; extra digits

9. Spine:
Neural tube defects

10. External genitalia:
Male: Hypospadias; undescended testis; hydrolecele; Female: fused labia; enlarged clitoris.

The infected newborn (31)
Neonatal infection is particularly frequent in Africa. It is the main cause of neonatal mortality in many developing countries. Contributing factors are related to the environment (traditional practices, poor hygiene), the course of pregnancy (prematurity, rupture of membrane) and constitutional fragility (prematurity, small-for-date, dysmaturity). Transplacental contamination is one of the important cause of infection in newborns. Early detection of newborns at risk of transplacental infection is important, so that close monitoring and preventive action may be implemented.

NEONATAL TETANUS:
It can be prevented by immunization of pregnant women and zero-vaccination of newborns in case of at-risk delivery. These measures have proved effective in those countries where they are systematically applied.

CONGENITAL SYPHILIS:
The frequency of congenital syphilis is on rise in some large African cities. Diagnosis is essentially based on the evidence of syphilis in the mother, since clinical signs of congenital syphilis often do not occur at once. In case of doubt and if there is risk of inadequate subsequent medical surveillance of the baby, treatment with 2.4 to 4.8 million U of Benzathine Penicillin may be recommended.

NEWBORN WITH AN HIV-POSITIVE MOTHER:
Chronic carriers of hepatitis virus are extremely frequent in some countries. Babies may be infected at birth when the mother is a carrier of this virus. The risk of transmission is somewhere around 20 per cent when the mother has the HBs antigen only, and around 90 per cent when she also has the HBe antigen. Transmission occurs through the blood and the genital secretions and therefore affects the newborn during the immediate perinatal period and throughout infancy. It is not a contraindication of breast-feeding.

If the newborn is infected, there is a risk that he/she will become a chronic carrier, and tend to HIV-positive mothers, hepatits, cirrhosis or primary cancer of liver during adulthood. 50 per cent of severe cases of infantile hepatitis before age one year are the outcome of untreated perinatal transmission. It is possible to prevent perinatal transmission by seroprophylaxis combined with vaccination - an intra-muscular injection of 0.5 ml of hepatitis B immunoglobulin along with hepatitis B vaccine within 24 hours of birth. The vaccine must be repeated at 6, 10 and 14 weeks of age.

This prophylaxis has proved effective. The real problem is to detect mothers who are chronic carriers of the HBs antigen, and the high cost of prevention.

NEWBORN WITH AN HIV-POSITIVE MOTHER:
The rapport of the propagation of HIV infection is a source of great concern. About 33 per cent babies born to HIV-positive mothers get infected. Transmission of infection mostly occurs at the end of the pregnancy, and it is not influenced by the type of delivery. The virus has been isolated in breast-milk. Although there is probably a risk of transmission of infection through breast-milk, prohibiting breast-feeding is debatable, as it is so essential for the survival of newborn in developing countries. The risk of transmission depends on the severity of the mother’s case. It is higher from mothers with AIDS, but may also occur from aperositive cases. Unfortunately, unlike hepatitis B, there is no prevention available for newborn at present. The question of whether to perform BCG vaccination raises - it is contraindicated in infected children, and therefore, should not be given in the offspring of HIV-positive mothers until it is determined whether the baby is infected or not. This is only feasible at the end of several months when the maternal antibodies are completely eliminated (31).

MEASURING THE BABY
Measurements of birth-weight, length (height) and head circumference are the simplest and one of the reliable methods by which the health and maturity of a baby is evaluated.

1. Birth-weight:
The birth-weight should be taken preferably within the first hour of life, before significant post-natal weight loss has occurred (32). The naked baby should be placed on a clean towel on the scale pan. In home delivery, weight is taken by placing the baby in a sling bag using a salver weighing scale. The baby is weighed to the nearest 10g and according to the standard method for weight measurement.

The average birth-weight of infants is lower in many developing countries than it is in developed countries. There are reasons to believe that this difference is not of genetic origin but is due largely to maternal malnutrition.

2. Length (height):
This need not be taken immediately if the baby’s condition gives rise to any anxiety, but should be recorded within the first 3 days. Length can be taken most accurately with a measuring board (infantometer) with a fixed head piece on which the infant lies supine with its legs fully extended and the feet flexed at right angles to the lower legs. Two people are needed to hold the baby correctly. The sliding board is moved firmly against the feet before the reading is taken. Length is taken to the nearest 0.1 cm.
3. Head circumference
This measurement may change slightly during the first 3 days owing to moulding during labour. It is taken with a tape measure at the maximum circumference of the head in the occipito-frontal diameter.

The purpose of taking these measurements are:
(i) to assess the baby’s size against known standards for gestation
(ii) to compare the size with estimated period of gestation
(iii) to use a baseline against which subsequent progress can be measured.

Anthropometric measurements may be classified as (CS):
(a) Weight
(b) Length
(c) Perimeters
(d) Diameters
(e) Skinfold thickness

Weight:
Length:
Total height, sitting height, heel length
Head, chest, abdomen, arm, calf
Biacromial, bipectoral, biacromial, bicipital, bicondylar, bisceps, biceps, subscapular

NEONATAL SCREENING
The object of screening newborns is primarily to detect infants with treatable genetic, developmental and other abnormalities, and secondarily, to provide their parents with genetic counselling. The Apgar score and routine clinical examinations are simple screening tests which should be carried out on all newborn infants. 10 to 15 ml of cord blood should be collected at birth and saved in the refrigerator for 7 days for typing, coombs’ testing and other tests if needed. Recent years have witnessed development of numerous tests for screening congenital metabolic disorders, inherited haemoglobinopathies and red cell disorders. Since these diseases are rare, general screening of the population for them is neither justified nor technically possible. However, only a few tests qualify for a screening programme. The most common disorders which are screened are discussed below.

(a) Phenylketonuria (PKU): PKU is a rare (incidence 1 in 10,000—20,000 births) disorder of amino acid metabolism. This is an autosomal recessive trait in babies who are homozygous with a deficiency in the enzyme phenylalanine hydroxydase (PAH) which normally converts phenylalanine to tyrosin. The deficiency results in raised serum phenylalanine concentrations causing mental retardation and tendency to seizures if the child does not receive low phenylalanine diet. Mass screening of blood phenylalanine in neonate is performed in many countries by the Guthrie test. It is possible to test for all three types of metabolic error, namely PKU, galactosaemia and maple syrup urine disease by taking blood from the 6—10 days old baby by heel prick and collecting 3 or 4 separate drops of it on thick absorbent filter paper. The treatment of PKU consists of a diet free of phenylalanine. Cautions dietary management in affected children results in normal physical and mental development.

(b) Neonatal hypothyroidism: This is the most common disorder that is screened. Congenital hypothyroidism leads to serious sequelae, including severe mental retardation, which can be prevented if medical treatment is given within the first 1—2 months of life. The test involves measuring the radio-immuno-assays of the thyroid hormone T4 or the thyroid-stimulating hormone (TSH). By examining the cord blood of newborns, potential victims of ID can be identified and proper prevention can be taken at such an early stage of life. Coombs’ test: This is done routinely on infants of all Rh-negative mothers. D) Sickle cell or other haemoglobinopathies: Haemoglobin electrophoresis is done on infants whose mothers have sickle cell or other haemoglobinopathies, e.g. thalassaemia, G6PD.

Identification of “at-risk” infants
The number of infants (and children 1—6 years of age) in a community, or attending a child health clinic, may be so large that it may not be possible to give sufficient time and attention to all of them. It is therefore necessary to identify particularly those “at-risk” and give them special intensive care, because it is these “at-risk” babies that contribute so largely to perinatal, neonatal and infant mortality. The basic criteria for identifying these babies include:

1. Birth weight less than 2.5 kg
2. Twins
3. Birth order 5 and more
4. Artificial feeding
5. Below 70 per cent of the expected weight (i.e., I and III degrees of malnutrition)
6. Failure to gain weight during three successive months
7. Children with PEM, diarrhoea
8. Working mother or one parent.

Late neonatal care
The remaining three weeks of the neonatal period carry the common and serious hazards of infection and failure of satisfactory nutrition. Diarrhoea and pneumonia take a heavy toll of life in infants exposed to an unsatisfactory environment. The case fatality rate of what normally would be trivial episodes can increase dramatically when elementary care is not given.

LOW BIRTH WEIGHT
The birth weight of an infant is the single most important determinant of its chances of survival, healthy growth and development.
There are two main groups of low birth weight babies—those born prematurely (short gestation) and those with foetal growth retardation. In countries where the population of low birth weight infants is less, short gestation period is the major cause. In countries where the proportion is high (e.g. India), the majority of cases can be attributed to foetal growth retardation. By international agreement low birth weight has been defined as a birth weight of less than 2.5 kg (upto and
including 2009 g), the measurement being taken preferably within the first hour of life, before significant postnatal weight loss has occurred (38). Apart from birth weight, babies can also be classified into 3 groups according to gestational age, using the word "preterm", "term" and "postterm", as follows (32):

a. Preterm: Babies born before the end of 37 weeks gestation (less than 299 days).

b. Term: Babies born from 37 completed weeks to less than 42 completed weeks (259 to 293 days) of gestation.

c. Postterm: Babies born at 42 completed weeks or any time thereafter (294 days and over) of gestation.

A LBW infant then, is any infant with a birth weight of less than 2.5 kg regardless of gestational age. It includes two kinds of infants:

**PRETERM BABIES (9, 33A)**

Preterm is defined as babies born alive before 37 weeks of pregnancy are completed. There are sub-categories of preterm birth, based on gestational age:

- extremely preterm (<28 weeks)
- very preterm (28 to <32 weeks)
- moderate to late preterm (32 to 37 weeks).

These are babies born too early. Their intrauterine growth may be normal. That is, their weight, length and development may be within normal limits for the duration of gestation. Given good neonatal care, these babies may catch-up growth and by 2 to 3 years of age will be of normal size and performance.

**INCIDENCE**

More than 1 in 10 of the world’s babies born in 2010 were born preterm, making an estimated 15 million preterm births (defined as before 37 weeks of gestation) of which more than 1 million died as a result of their prematurity. Prenatal care is now the second-leading cause of death in children under 5 years, and the single most important cause of death in the critical first month of life. For the babies who survive, many face a lifetime of significant disability.

**Causes of preterm births (9)**

Preterm birth is a syndrome with a variety of causes which can be classified into two broad subtypes: (1) spontaneous preterm birth (spontaneous onset of labor or following prelabour premature rupture of membranes (pPROM) and (2) provider-initiated preterm birth (defined as induction of labor or elective caesarean birth before 37 completed weeks of gestation) for maternal or fetal indications (both ‘urgent’ or ‘discretionary’), or other non-medical reasons.

Spontaneous preterm birth is a multi-factorial process, resulting from the interplay of factors causing the uterus to change from quiescence to active contractions and to birth before 37 completed weeks of gestation. The precursors to spontaneous preterm birth vary by gestational age, social and environmental factors, but the cause of spontaneous preterm labor remains unidentified in up to half of all cases. Maternal history of preterm birth is a strong risk factor and most likely driven by the interaction of genetic, epigenetic and environmental risk factors.

Elevated risk of preterm birth also demands increased attention to maternal health, including the antenatal diagnosis and management of NCDs and other conditions known to increase the risk of preterm birth. Premature babies, in turn, are at greater risk of developing NCDs, like hypertension and diabetes, and other significant health condition later in life, creating an intergenerational cycle of risk. The link between prematurity and increased risk of NCDs takes on an added public health importance when considering the reported increase in the rates of both worldwide. Table 4 summarizes the types of preterm births and the risk factors involved.

**Source**: (9)

**SMALL-FOR-DATE (SFD) BABIES**: These may be born at term or preterm. They weigh less than the 10th percentile for the gestational age. These babies are clearly the result of retarded intrauterine foetal growth.

**Computation**: The percentage of LBW babies is computed as:

\[
\text{LBW babies with birth weight less than 2.5 Kg} \times 100
\]

Total number of live births

The factors associated with intrauterine growth retardation are multiple and interrelated to mother, the placenta or to the foetus. The maternal factors include malnutrition, severe anaemia, heavy physical work during pregnancy, hypertension, malaria, toxemia, smoking, low economic status, short maternal stature, very young age,
high parity and close birth spacing, low education status etc. (34). The placental causes include placental insufficiency and placental anomalies. The foetal causes include foetal abnormalities, intrauterine infections, chromosomal abnormality and multiple gestation.

SFD babies have a high risk of dying not only during the neonatal period but during their infancy, thus significantly raising the rate of infant and perinatal mortality and contribute greatly to immediate and long term health problems. Most of them become victims of protein-energy malnutrition and infections.

In the developing countries, adverse prenatal and postnatal development of the child is associated with 3 interrelated conditions: malnutrition, infection and unregulated fertility which are often due to poor socio-economic and environmental conditions.

IMPORTANCE

LBW is one of the most serious challenges in maternal and child health in both developed and developing countries. Its public health significance may be ascribed to numerous factors – its high incidence; its association with mental retardation and a high risk of perinatal and infant mortality and morbidity (half of all perinatal and one-third of all infant deaths are due to LBW); human wastage and suffering; the very high cost of special care and intensive care units and its association with socio-economic underdevelopment (35).

LBW is the single most important factor determining the survival chances of the child. Many of them die during their first year. The infant mortality rate is about 20 times greater for all LBW babies than for other babies. The lower the birth weight, the lower the survival chance. Many of them become victims of protein-energy malnutrition and infection. LBW is thus an important guide to the level of care needed by individual babies. LBW also reflects inadequate nutrition and ill-health of the mother. There is a strong and significant positive correlation between maternal nutritional status and the length of pregnancy and birth weight. A high percentage of LBW therefore points to deficient health status of pregnant women, inadequate prenatal care and the need for improved care of the newborn.

PREVENTION

Experts opine that the rates of LBW babies could be reduced to not more than 10 per cent in all parts of the world (36). It is clear from the multiplicity of causes that there is no universal solution. Interventions have to be cause-specific. Main attention has been given in recent years to ways and means of preventing LBW through good prenatal care and intervention programmes, rather than "treatment" of LBW babies born later.

DIRECT INTERVENTION MEASURES

The evidence of LBW can be reduced if pregnant women at risk are identified and steps are taken to reduce the risk. For this approach the women need to be identified early in pregnancy. To achieve this goal, the mothers health card – which is simple and can be used by primary health care worker – has been found very useful. The risk factors are: mother’s malnutrition, heavy work load, diseases and infections and high blood pressure. Added to malnutrition, too many and too frequent pregnancies contribute to the continued depletion of her body. Both malnutrition and morbidity due to infections during pregnancy are amenable to correction or can be prevented. Some of the direct interventions are as follows:

(i) Increasing food intake: Studies have shown that even a relatively small dietary improvement in the malnourished pregnant mother, even during the last trimester, can result in a significant improvement in the birth weight of an infant. In Southern India, treatment of anaemic mothers led to an increase in birth weight of offspring. Direct intervention covers a wide range of activities, viz., supplementary feeding, distribution of iron and folacidal tablets, fortification and enrichment of foods, etc. (ii) Controlling infections: Many maternal infections go unrecognized. They should be diagnosed and treated (e.g., malaria, urinary tract infection, infections due to cytomegalovirus, toxoplasmosis, rubella and syphilitic infection) or otherwise prevented. These infections can affect foetal growth in several ways. (iii) Early detection and treatment of medical disorders: These include hypertension, toxemia, and diabetes.

INDIRECT INTERVENTION

Family planning, avoidance of excessive smoking, improved sanitation measures, and measures aimed at improving the health and nutrition of young girls, each have a role to play. These measures can be expected to be more effective and to have lasting effects only if, at the same time there are improvements in the socio-economic and environmental conditions and in the distribution of health and social services especially in the under-served areas. Government support could be provided through such measures as maternity leave with full wages and child benefits.

Fig. 3 summarizes the integrated services delivery package for maternal and newborn care.

TREATMENT

From the point of view of treatment, LBW babies can be divided in to 2 groups: (a) those under 2 kg and (b) those between 2-2.5 kg. The first group requires first class modern neonatal care (which is hardly available globally) in an intensive care unit until the weight reaches that of the best care, otherwise for low birth-weight babies. They include skin-to-skin positioning of a baby on the mother’s chest; adequate nutrition through breast-feeding; ambulatory care as a result of earlier discharge from hospital and support for the mother and her family in caring for the baby (37).

The intensive care comprises of: (a) Incubatory care, that is, adjustment of temperature, humidity and oxygen supply. There is increasing evidence that low levels of oxygen in a baby’s blood stream (hypoxia) can produce cerebral palsy. Therefore, continuous monitoring of the level of oxygen in baby’s blood stream is now carried out in the best incubatory care units. If the oxygen is excessive, it may lead to retrolateral fibroplasia. (b) Feeding: Breast-feeding is rarely possible – the baby cannot suck. However, breast milk

**FEEDING OF INFANTS**

A detailed discussion of the feeding of infants is outside the scope of this book. However, a brief mention may be made of some of the important aspects of the problem.

(1) Breast-feeding

Under any circumstances, breast milk is the ideal food for the infant. No other food is required by the baby until 6 months after birth. Under normal conditions, Indian mothers secrete 450 to 600 ml of milk daily with 1.1 gm protein per 100 ml. The energy value of human milk is 70 kcal per 100 ml.

A child who is breast-fed has greater chances of survival than a child artificially fed. Prolonged breast feeding does protect the infant from early malnutrition and some infections. The data suggests that infant mortality rates in developing countries are 5-10 times higher among children who have not been breast-fed or who have been breast-fed for less than 6 months. Despite the marked advantages of breast-feeding, its popularity has declined significantly in many parts of the world.
Advantages of breast-feeding

Among the advantages of breast milk are the following:

1. It is safe, clean, hygienic, cheap and available to the infant at correct temperature (2) if it fully meets the nutritional requirements of the infant in the first few months of life (3) it contains antimicrobial factors such as microphages, lymphocytes, secretory IgA, anti-streptococcal factor, lysozyme and lactoferrin which provide considerable protection not only against diarrhoeal diseases and necrotizing enterocolitis, but also against respiratory infections in the first months of life (4) it is easily digested and utilized by both the normal and prematurity babies (5) it promotes "bonding" between the mother and infant (6) its high is good for the baby – it helps in the development of jaws and teeth (7) it protects babies from the tendency to obesity (8) it prevents diarrhoea and reduces infant mortality (9) it provides several biochemical advantages such as prevention of neonatal hypocalcaemia and hypomagnesaemia (10) it helps parents to space their children by prolonging the period of infertility and (11) special fatty acids in breast milk lead to increased intelligence quotients and better visual acuity. A breast-fed baby is likely to have an IQ of around 8 points higher than a non-breast fed baby (39).

Early initiation of breast-feeding lowers the mother's risk of postpartum haemorrhage and anaemia, boosts mother's immune system, delays next pregnancy and reduces the insulin of diabetic mothers. It protects mothers from ovulation and breast cancers and osteoporosis (39).

It is neither necessary nor desirable to train a baby to "feed by the clock". It should be explained to the mother, however, that intervals between feeds are necessary for herself and for the baby, though they may vary between 1 to 4 hours, according to the baby's needs, size, strength of suckling and the mother's milk supply.

(2) Artificial feeding

The main indications for artificial feeding are failure of breast milk, prolonged illness or death of the mother. It is crucial for the baby to be fed "breast-milk substitutes" – e.g., dried whole milk powder, cow milk from a cow or other animal, or commercial formula.

PRINCIPLES OF ARTIFICIAL FEEDING

In planning an artificial feed, the nutritional needs of infants should be kept in view. These include:

1. Infants require an average of 100 kcal of energy per kg of body weight per day, i.e., about 150 ml of milk per kg of body weight each day.

2. The estimated protein requirement is about 2 g/kg of body weight during the first 6 months; it declines to about 1.5 g/kg by the end of one year. This works out to 13-14 g protein daily during the first year of life. In terms of calories, 8 to 10 per cent of calories are given as protein

3. The carbohydrate requirement is about 10 g/kg of body weight daily.

4. After 4 months of age, undiluted boiled and cooled milk should be given

5. Infants need feeding at frequent intervals about 6-8 times a day; older babies 5 times a day.

6. During illness (e.g., fevers) the calorie need is increased, and it should be met.

(a) DRIED MILK: The safest milk is undoubtedly dried whole milk, which is scientifically prepared for infant feeding. It is free from bacteria; there is little danger from flies; it does not become sour and is simple to reconstitute. It is usually fortified with vitamins. But it is expensive and, therefore, beyond the reach of many Indian families.

(b) COW'S MILK: A cheaper alternative which is well within the reach of many Indian families is cow's milk, which in fact is widely used for infant feeding. Most health workers give very conflicting advice on the use of cow's milk for infant feeding. A small minority of over-enthusiastic paediatricians recommend undiluted cow's milk right from the birth, forgetting that the fact that human milk is made for the human baby and cow's milk for the calf. Both cannot be equated. Most authorities in India and abroad including the World Health Organization have persistently recommended dilution of cow's milk during the first 2 months in order to reduce the solute load on neonatal kidneys. The Government of India is the Ministry of Health and Family Welfare in the "Manual for Health Worker (Female) Vol. I (1978) have also recommended dilution of cow's milk during the first two months. A suggested schedule for infant feeding with cow's milk is given in Table 5.

Source: (40)

Artificial feeding is a hazardous procedure in poor homes because of the dangers of contamination and over-dilution of the feeds. The composition of cow's milk and human milk is given in Table 6. Table 6 shows that cow's milk and human milk are dissimilar in many respects. The differences may be seen as great as the difference between "brain" and "brain", (a) PROTEIN: One of the striking differences is the low protein content of human milk; this is about 3 times less than in cow's milk and lower than in most mammals. The proteins in human breast milk and in cow's milk are completely different. Human milk contains more casein, essential for the premature, and less histamine than cow's milk. It is rich in taurine, indispensable for infants, but which, they unlike adults, are unable to synthesize. Breast milk is almost completely digested and utilized for growth, whereas much of cow's milk protein is excrated by the infant undigested producing whitish curdy stool. Breast milk contains other proteins whose functions are not nutritive, but anti-infective, e.g., IgG, lysozyme, living cells. Human milk is virtually a "living" fluid. (b) FATS: Mother's milk is especially rich in fats, which represents between 35-50 per cent of total energy value. There are two main ways in which the fats of human milk differ from those of other milks – first, levels of essential polyunsaturated fatty acids, especially linoleic acid and alpha-linolenic acid are higher in human milk than is cow's milk; secondly, the fats of human milk are easier for the baby

To digest and absorb than are those of cow’s milk. With cow’s milk, unabsorbed fatty acids tend to bind with calcium and prevent it from being absorbed. Although there is less calcium in human milk than in cow’s milk, it is much better absorbed. (c) CARBOHYDRATES: Human milk contains more lactose than most other milks. It may be specially useful for the growing brain. In the intestine, lactose helps the “right” kind of bacteria (i.e., Lactobacillus bifidus) to grow. Lactobacillus and lactose help to keep the intestinal contents acidic, which inhibits the growth of harmful bacteria. Lactose plays an important role in maintaining low electrolyte concentration. (d) VITAMINS AND MINERALS: If the mother takes adequate amounts of vitamins, there is no reason why the child should have a vitamin supplement. The earlier teaching that human milk was deficient in vitamin D is no longer accepted. Vitamin D is present in human milk in water-soluble form. Human milk contains more vitamin A and vitamin C than cow’s milk. Another factor which was supposed to be deficient in human milk was iron, but again recent work has shown that iron contained in human milk has a high level of bioavailability, thanks to complex phenomena (the action of lactoferrin, acidity of the digestive tract, presence of appropriate proportions of zinc and copper). The coefficient of uptake of the iron in breast milk may be as high as 70 per cent, whereas it is only 30 per cent for cow’s milk and infant formulas (41), and no iron supplement is necessary for the baby reared on human milk. Human milk is rich in copper, selenium and cobalt than cow’s milk. It contains less sodium than cow’s milk and does not put any unnecessary strain on the infant’s kidneys. The calcium/phosphorus ratio is high, so that the uptake of calcium is better than cow’s milk. The high phosphorus content of cow’s milk causes this mineral to be assimilated to the detriment of calcium. It has the added disadvantage of combining with certain fatty acids to form non-soluble calcium soap.

WEANING: Weaning is not sudden withdrawal of child from the breast. It is a gradual process starting around the age of 6 months. The child’s milk intake should start to decrease at about 12 months. BFH in sustain growth beyond 6 months. It should be supplemented by suitable foods rich in protein and other nutrients. These are called “transition foods”. The transition foods are particularly exposed to the deleterious synergistic interaction of malnutrition and infection. Weaning, if not done properly, is often followed by diarrhoea and may lead to growth failure leading to kwashiorkor, marasmus and immunodeficiency marked by maculative and persistent infections which may be fatal. A knowledge of weaning foods and practices is an important aspect of preventive and social paediatrics. At the age of one year, the child should receive solid foods consisting of cereals, pulses, vegetables and fruits. There is now enough evidence to show that children can be properly weaned by local foods of a kind usually consumed by the older children and adults in their families. Efforts should therefore be made to design and promote the use of adequate home-made weaning foods.

**Baby friendly hospitals initiatives**

Since 1993 WHO’s efforts to improve infant and young child nutrition have focused on promoting breast feeding. It has been calculated that breast feeding could prevent deaths of at least one million children a year. A new "Baby friendly hospital initiative" (BFHI), created and promoted by WHO and UNICEF, has proved highly successful in encouraging hospitals to practice breastfeeding (41). BFH is supported by the major professional medical and nursing bodies in India. The Global BFHI has listed ten steps which hospitals can follow to "achieve the baby-friendly hospital” status: (1) Have a written breast feeding policy that is routinely communicated to all health care staff; (2) Train all health care staff in skills of breastfeeding; (3) Process women about the benefits and management of breast feeding; (4) Help mothers initiate breast-feeding within one hour of birth; (5) Provide mother, how to breast-feed and maintain lactation, even if they are separated from their infants; (6) Give newborn infants no food or drink other than breast milk, not even water, unless medically indicated; (7) Practice room-in — that is, allow mothers and infants to remain together 24 hours a day; (8) Encourage breast-feeding on demand; (9) Give no artificial tests or pacifiers (also called dummies or soothers) to breast-feeding infants; and (10) Foster the establishment of breast-feeding support groups and refer mothers to them on discharge from the hospital or clinic. The "Baby friendly" hospitals in India are also expected to adopt and practice guidelines on other interventions critical for child survival including antenatal care, clean delivery practices, essential newborn care, immunization and ORT (43).

**National guidelines on infant and young child feeding**

In view of the vulnerability of young infant to the risk of breast milk substitutes, the Government of India enacted the
GROWTH AND DEVELOPMENT

The new norms of infant and young child feeding i.e., exclusive breast-feeding for the first 6 months (replacing the 4-6 months age range of earlier guidelines), introduction of complementary foods at 6 months while continuing breast-feeding up to the age of 2 years or beyond; replaces the previous policy. The infant milk substitutes, feeding bottles and infant foods (Regulation of Production, Supply and Distribution) Amendment Act 2003, was passed and came into action since 1st January 2004 (39). Go-to set to be achieved by year 2007 were:

1. Intensify nutrition and health education to improve infant and child feeding and caretaking practices so as to (a) bring down the prevalence of undernutrition in children, under three years from the current level of 47 per cent to 40 per cent; (b) reduce prevalence of severe undernutrition in children in the 0-6 years age group by 50 per cent.

2. Enhance early institution of breast-feeding (colostrum feeding) from the current level of 15.5 per cent to 50 per cent.

3. Enhance the exclusive breast-feeding rate for the first six months from the current rate of 55.2 per cent (for 0-3 months) to 88 per cent; and

4. Enhance the complementary feeding rate at six months from the current level of 33.5 per cent to 75 per cent.

GROWTH AND DEVELOPMENT

1. Definition

A phenomenon peculiar to the paediatric age group is growth and development. The term growth refers to increase in the physical size of the body, and development to increase in skills and functions. Growth and development are considered together because the child grows and develops as a whole. Growth and Development include not only physical aspect, but also intellectual, emotional and social aspects.

Normal growth and development take place only if there is optimal nutrition, if there is freedom from recurrent episodes of infections, and if there is freedom from adverse genetic and environmental influences. MCH care is concerned with the process of growth and development, which is the foundation of human life. It is the nature of this process of physical and psychological growth and development of the child which is crucial for his life or ill-health, for life or death.

Determinants of growth and development

It is beyond the scope of this book to delve into the subject of growth and development which indeed is a vast one, except to make a passing reference to some of the more important factors influencing it. Briefly these are:

(1) GENETIC INHERITANCE: Genetic factors influence growth and development, especially height and weight, mental and social development and personality. (2) NUTRITION: Nutrition influences growth and development before as well as after birth. In fact, retardation of growth rate is an indication of malnutrition. When the diet is improved the child begins to grow in height and weight. (3) AGE: Growth rate is maximum during foetal life, during the first year of life and then again at puberty. At other periods, growth is slower. (4) SEX: At about the age of 10 to 11 years, female children show a sudden increase in height and weight. This growth spurt corresponds to puberty. In male children, the growth spurt occurs a little later, i.e., between 12 and 13 years. (5) PHYSICAL SURROUNDINGS: Sunshine, good housing, lighting and ventilation have their effects on growth and development.

(6) PSYCHOLOGICAL FACTORS: Love, tender care and proper child-parent relationship do affect the social, emotional and intellectual development of children.

(7) INFECTIONS AND PARASTISS: Certain infections of the mother during pregnancy (e.g., rubella, mumps) affect the intrauterine growth of the foetus. Infections after birth (e.g., diarrhoea, measles) slow down growth and development, especially in the malnourished child. The intestinal parasites (e.g., roundworms) by consuming considerable quantities of nutrients hamper growth and development. (8) ECONOMIC FACTOR: The standard of living of the family is an important factor. Children from well-to-do families have better height and weight. The economic factor is connected with the nutrition and living of the people.

(9) OTHER FACTORS: These comprise the birth order of the child, birth spacing, birth weight in single and multiple pregnancies, education of the parents, etc. In short, a normal childhood implies proper physical, mental and emotional development, and is a prerequisite for a full adult life. The study of normal development and its determinants is the basis for paediatric education.

The process of growth from birth to age 20 may be represented diagrammatically in 3 curves (Fig. 4) which shows the level accomplished (as a percentage of development between birth and maturity). These curves are so drawn that height at age 20 corresponds to 100 on the vertical scale. It will be seen from Fig. 4 that the growth of the brain is spectacular during the pre-school age.

2. Normal growth

CONCEPT OF NORMALITY

When speaking of human growth and development, mention must be made of the term 'normality defining normal growth'. A normal child may be defined as one whose characteristics fall within the range of measurements accepted as normal for the particular age and sex and reference age group. Conventionally, these limits - the limits of normal variation - are assumed to include two standard deviations above and below the mean (i.e., between the 3rd and the 97th centiles). This presupposes the availability of accurate measurement techniques of growth, and a satisfactory set of reference values or standards for comparison.

As far as physical development is concerned, we have measurement techniques. For example, we measure growth in terms of kilograms and centimetres. But very great difficulties are encountered in connection with psychomotor, emotional and social development: most measurement techniques are based on observations such as "milestones of development."

Methods of assessment (44, 45)

In childhood, the parameters of growth generally used are: weight, height (or length in infants), and head and chest circumference. These characteristics are measured and compared with the reference standards. Three methods are generally used for making comparisons: (i) The first method is based on mean (or median) values. The median, rather than mean is used where possible because of the skewed distribution of most anthropometric measurements.
A variation of 2 standard deviations from either side of the mean (or median) is considered as within normal limits. (ii) The second method is by means of percentile or (centiles). Percentiles are easier to understand than standard deviations. Percentiles refer to the percentage of individuals falling below a particular level. By definition 3 per cent of children are below the 3rd percentile and a further 3 per cent are above the 97th percentile. The remaining 94 per cent of individuals who fall between these two lines (i.e., between 3rd and 97th percentiles) should therefore be regarded as being within the range of "normal." However, the 6 per cent of the children outside this range may not necessarily be "abnormal," particularly if their growth is parallel with their centile lines. A measurement outside the 3 standard deviation (above 99th and below 1st centile) is more likely to indicate a significant degree of abnormality. (iii) Thirdly, it is also possible to assess the growth of a child by such indices as weight for length, and weight for height. These are age-independent indices.

The assessment of growth may be longitudinal or cross-sectional. Longitudinal assessment of growth entails measuring the same child at regular intervals. This provides valuable data about a child’s progress. Cross-sectional studies are also essential to compare a child’s growth with that of his peers. Cross-sectional comparisons involve large numbers of children of the same age. These children are measured and the range of their measurements (e.g., weight, height) is plotted, usually on percentile charts.

Reference values

For national and international comparisons and for monitoring, reference or “standard” values of growth are essential. The well-known reference standards are:

(i) Harvard (or Boston) standards (46) : These are based on observations made on children in Boston from 1930 to 1956. They have been carefully compiled longitudinally on a large series of children, mostly from North European origin. They became widely used throughout the world. (ii) WHO reference values (47, 48) : The Harvard values were replaced by WHO reference values for weight and height. These values were based on extensive cross-sectional data assembled by the United States National Centre for Health Statistics (NCHS) which were considered the best available for international use. The WHO reference values are used for children up to 5 years of age since the influence of ethnic or genetic factors on young children at this age period is considered insignificant, given the similar socio-economic environment. (iii) Indian standards (49) : The Indian Council of Medical Research (ICMR) undertook a nationwide cross-sectional study during the year 1956 and 1965 to establish the much-needed reference standards of growth and development of Indian children, for the country as a whole, as well as for each of the states in the country. As the Indian data are based on measurements of children belonging to the lower socio-economic groups which form the majority of Indian communities, the values cannot be considered as representing standard values (50).

The use of local standards of reference is not recommended unless these are based on well-nourished and healthy samples of local population. Further, local standards do not permit international comparisons (51). It was the opinion of WHO that countries or regions might eventually develop their own reference standards; in the interim, the WHO reference values should provide an effective substitute (49).

Reference versus standard values

A distinction must be made between reference values and standard values. If the values are derived from a population
A baby should gain at least 500 gram wt. per month in the first three months of life. That is the minimum. The children who gain less weight are malnourished. It is usual for babies to gain about 1 kg a month, especially in the first 3 months. Healthy babies, on an average double their birth weight by 5 months, and triple by the end of first year and quadruple by the age of two. During the first year, weight increases by about 7 kg. After that the increase in weight is not so fast – only about 2.5 kg during the second year and from then until puberty by about 2 kg per year. The weight and height gain patterns in India are as shown in Table 8.

In different parts of India, the average birth weight is between 2.7 and 2.9 kg (54). The Indian infant manages to grow well up to the age of 3-4 months, even at the expense of its malnourished mother. Thereafter, the growth falls due to lack of supplementary feeding (55). However, Indian children from well-to-do families display growth patterns as good as their counterparts in the Western world (49).

Source: (55)
Weight-for-age is often used to classify malnutrition and determine its severity. Jelliffe suggested that 90 per cent of the median weight-for-age of the reference be the cut-off point below which children could be considered malnourished.

2. Height (length)-for-age

Height should be taken in a standing position without foot support. A height machine is not available, the measuring scale fixed to the wall can be employed. This arrangement is suitable for children 2 years and above. The measuring scale should be capable of measuring to an accuracy of 0.1 cm (48). A very great effort should be made to measure children accurately. Errors in the measurement of a young child may lead to significant errors in the classification of the nutritional status. The WHO standards (2006) for height-for-age are as shown in Table 9.

The length of a baby at birth is about 50 cm. It increases by about 25 cm during first year, and by another 12 cm during the second year. During growth spurt, boys add something like 20 cm in their height, and girls gain about 16 cm. The spurt is followed by a rapid slowing of growth. Indian girls reach 90 per cent of their final height on an average by the age of 16.5 years, and boys reach the same stage by the age of 17.75 years. With the exception of a few ethnic groups, there is evidence showing that all children have a similar growth potential.

Height is a stable measurement of growth as opposed to body weight. Whereas weight reflects only the present health status of the child, height indicates the events in the past also. The use of growth (height) centile chart is particularly valuable in studying the trend of height curve.

Low height for age: This is also known as nutritional stunting or dwarfing. It reflects past or chronic malnutrition. The cut-off point commonly taken for the diagnosis of stunting is 90 per cent of the United States NCHS height-for-age values (54). The WHO recorded the use of 2SD below the median reference as the cut-off point.

3. Weight-for-height

Height and weight are interrelated. Weight in relation to height is now considered more important than weightalone. It helps to determine whether a child is within range of "normal" weight for his height. For example, a child on the 75th centile of both his height and weight is neither overweight nor underweight, but a child on the 75th centile of his weight chart and the 25th centile of his height chart is clearly overweight.

Low weight for height: This is also known as nutritional wasting or emaciation (acute malnutrition). It is associated with an increased risk of mortality and morbidity (56). A child who is less than 70 per cent of the expected weight-for-height is classed as severely wasted.

The WHO has compiled reference values for children giving weight according to height. For details see reference 53.

Weight records

Weight records are generally kept by all infant clinics; the aim is the prevention of underfeeding, and in the developing world, the weight chart is an important tool in the prevention of malnutrition.

4. Head and chest circumference

At birth the head circumference is about 34 cm. It is about 2 cm more than the chest circumference. By 6 to 9 months, the two measurements become equal, after which the chest circumference overtakes the head circumference. In severely malnourished children, this overtaking may be delayed by 3 to 4 years due to poor development of the thoracic cage. In an ICMR study (49), the crowning over of chest and head circumference did not take place until the age of two years and six months. This has been attributed to growth retardation in poor Indian children.

Besides increase in height and weight, the term "growth" also includes various physiological events which occur at predictable periods such as, dentition, ossification of bones and secondary sexual characteristics.

BEHAVIOURAL DEVELOPMENT

A closely related development is behavioural development. It is assessed in four fields:

Source: (53)
1. Motor development
2. Personal-social development
3. Adaptive development
4. Language development

The developmental landmarks or milestones of development provide an estimate of the time when the child can be expected to attain certain skills or points in development. Since the milestones are averages, each child is bound to differ from the other. For instance, some children sit up and speak earlier than others. Table 10 shows some of the normal developmental milestones and ages at which these are reached in the Indian context. When a child takes longer time to cross these milestones, the possibility of his being mentally handicapped should not be overlooked.

The behavioural development of the child is a complex affair. The work of ethologists and sociologists show how quickly the child's behaviour conform to the models adult society offers them. For proper behaviour development, the child must be assured emotional and moral stability, that is, a home where he will find bonds of affection, regular discipline and parents who accept him and provide him with models of balanced conduct. Many children will not find themselves in ideal conditions. They consequently have trouble with behaviour, speech, sleep and appetite and these problems will have to be anticipated, diagnosed and treated.

THE GROWTH CHART

The growth or "road-to-health" chart (first designed by David Morley and later modified by WHO) is a visible display of the child's physical growth and development. It is designed primarily for the longitudinal follow-up (growth monitoring) of a child, so that changes over time can be interpreted.

It is important to note that in the weight-for-age chart, the height of the child is not taken into consideration. This is because weight is the most sensitive measure of growth, and any deviation from "normal" can be detected easily by comparison with reference curves. A child can lose weight, but not height. In short, the growth chart offers a simple and inexpensive way of monitoring weight gain, and in fact child health over time.

1. WHO child growth standards, 2006 (53)

In 1993 the WHO undertook a comprehensive review of the uses and interpretation of anthropometric references. The review concluded that the NCHS growth references, which had been recommended for international use since the late 1970s, did not adequately represent early childhood growth and that new growth curves were necessary. A Multicentre Growth Reference Study (MGRS) was undertaken between 1997 and 2003 in Brazil, Ghana, India, Norway, Oman and USA and primary growth data and related information were gathered from 9,440 healthy breast-fed infants and young children (0 to 60 months boys and girls) from widely diverse ethnic background and cultural settings. In addition their mothers followed health practices such as breast feeding their children, and not smoking during and after pregnancy.

The new standards were generated for boys and girls aged 0-60 months – percentile and Z-score curves for length/height-for-age, weight-for-age, weight-for-length, weight-for-height and BMI-for-age. The last standard is an addition of the set of indicators previously available as part of the NCHS/WHO reference.

As expected, there are notable differences with the NCHS/WHO reference that vary by age, sex, anthropometric measure and specific percentile or Z-score curve. Differences are particularly important in infancy. Stunting will be greater throughout childhood when assessed using the new WHO standards compared to the NCHS/WHO reference. The growth pattern of breast-fed infant will result in a substantial increase in rate of underwater during the first half of infancy and a decrease thereafter. For wasting, the main difference is during infancy when wasting rate will be substantially higher using the new WHO standards. With respect to overweight, use of the new standards will result in a greater prevalence that will vary by age, sex and nutritional status of the index population.

The new WHO standards depict normal early childhood growth under optimal environmental conditions and can be used to assess children everywhere, regardless of ethnicity, socio-economic status and type of feeding.

Fig. 5 and 6 show the comparison of WHO with NCHS weight-for-age reference curve from birth to 5 years of age for boys and girls respectively (53).

![Table 10: Milestones of development](image-url)

The 'milestones' given here are approximations and to assess any individual child, all types of growth development and behaviour must be taken into account.

2. Growth chart used in India

India has adopted the new WHO Child Growth Standards (2006) in February 2009, for monitoring the young child growth and development within the National Rural Health Mission and the ICDS. The same standards will be used for research too in future.

These standards are available for both boys and girls below 5 years of age. With these new standards the child care workers will know when the nutrition and care needs of the child is being compromised and it will enable them to take timely corrective action at different levels.

A joint “Mother and Child Protection Card” has been developed, as shown in Fig. 7 and 8, which provides space for recording the family identification and registration, birth record, pregnancy record, institutional identification, care during pregnancy, preparation for delivery, registration under Janani Suraksha Yojana, details about immunization procedures, breast-feeding and introduction of supplementary food, milestones of the baby, birth spacing and reasons for special care. The chart is easily understood by the health workers and the mother, with a visual record of the health and nutritional status of the child. It is kept by the mother and brought to the health centre at each visit.

The growth chart shows normal zone of weight for age, undernutrition (below – 2 SD) and severely underweight zone (below – 3 SD). In some states like Maharashtra, the growth chart contains normal weight for age zone and undernutrition zone of grades one, second, third and fourth. It is the direction of growth that is more important than the position of dots on the line. The importance of the direction of growth is illustrated at the left hand, upper corner of the chart. Flattening or falling of the child’s weight curve signals growth failure, which is the earliest sign of the protein-energy malnutrition and may precede clinical signs by weeks and months. Such a child needs special care. The objective in child care is to keep the child in normal zone.

FIG. 7
ICDS growth chart for boys
Uses of growth chart

A growth chart has many potential uses:

1. **for growth monitoring** which is of great value in child health care
2. **diagnostic tool**: for identifying “high-risk” children. For example, malnutrition can be detected long before signs and symptoms of it become apparent
3. **planning and policy making**: by grading malnutrition, it provides an objective basis for planning and policy making in relation to child health care at the local and central levels
4. **educational tool**: because of its visual character, the mother can be educated in the care of her own child and encourage her to participate more actively in growth monitoring
5. **tool for action**: It helps the health worker on the type of intervention that is needed; it will help to make referrals easier
6. **evaluation**: it provides a good method to evaluate the effectiveness of corrective measures and the impact of a programme or of special interventions for improving child growth and development, and
7. **tool for teaching**: it can also be used for teaching, for example, the importance of adequate feeding; the deleterious effects of diarrhoeas.

The growth chart has been described as a passport to child health care (57). It has won international recognition and is now a standard method of monitoring children’s health and nutritional status.

**Alternative methods of growth monitoring**

Growth charting is only one method of growth monitoring. There are other indicators such as height-for-
CARE OF THE PRE-SCHOOL CHILD

Children between 1–4 years of age are generally called pre-school age children or toddlers. In the history of health services of many developing countries, their social and health needs were realized rather late. Today, more than ever before, the pre-school age child has become a focus for organized medical-social welfare activities, and their death rate is considered a significant indicator of the social situation in a country.

The pre-school age is distinguished by the following characteristics:

1. Large numbers

Pre-school age children (1–4 years) represent about 9.7 per cent of the general population in India. A large majority of these children live in rural and tribal areas and in urban slums. By virtue of their numbers, they are entitled to a large share of health and social services. Further, children are the human resources of the future. Their development is in the interest of the total national development; therefore, they need special attention. Unfortunately, pre-school age children are comparatively less attended to.

2. Mortality

The pre-school age (1–4 years) mortality in India is 2.3 per cent of all deaths. This high mortality which is largely due to infection and malnutrition is characteristic of this age group in underprivileged areas. Malnutrition was shown to be an underlying cause in 34 per cent of all deaths in young children and associated cause in no less than 46 per cent (42).

3. Morbidity

The data on the extent of morbidity of pre-school children are scarce. Some hospital records and a few surveys suggest that children in this age group are usually victims of PEM accompanied by retarded growth and development. Survey data indicates that the main morbidity problems are malnutrition and infections. The prevalence of severe protein-energy malnutrition ranged between 5–6 per cent, and mild protein energy malnutrition about 40 per cent. PEM is often associated with other nutritional deficiencies such as anemia, xerophthalmia, etc. Diarrhoea, diphtheria, tetanus, whooping cough, measles and other eruptive fevers, skin and eye infections, and intestinal parasitic infestations are usually common under the existing environmental conditions. At least 5 per cent of the pre-school age children belonging to poor socio-economic groups show signs of vitamin A deficiency. Accidents are also becoming frequent, especially burns and trauma from home accidents, and to an increasing degree, traffic accidents. Some childhood diseases and conditions do not kill their victims, but cause serious disability (e.g., blindness, paralysis); and some diseases become manifest later in life (e.g., heart disease and mental retardation). In many developing countries, periods of illness take up 25–30 per cent of the child’s life and each represents either loss of weight or failure to gain weight. These episodes are well documented by several authors (56).

4. Growth and development

The importance of the first 5 or 6 years of life of a child for its growth and development is well known. Any adverse influences operating on children during this period (e.g., malnutrition and infection) may result in severe limitations in their development, some of which at least are irreversible. The concept of vulnerability calls for preventive care and special actions to meet the biological and psychological needs inherent in the process of human growth and development (36).

5. Accessibility

While the infant may be easily reached, the toddler is hard to reach, and it is therefore difficult to look after his health. Special inputs are needed (e.g., day care centres, play group centres, children’s clubs) to reach the toddler and to bring him into the orbit of health care. Operation research all over the world has demonstrated that parents are unlikely to travel more than 5–8 kms to obtain medical care. For the toddler who needs to be carried, the distance may be reduced even further.

6. Prevention in childhood of health problems in adult life

Results of research indicate how events in early life (e.g. child’s diet, infections) affect its health when it becomes an adult, and how many conditions can be prevented through early action, for example, dental diseases in adulthood. Early treatment of streptococcal infection can prevent rheumatic heart disease. Longitudinal studies suggest that the foundations of obesity, hypertension, cardiovascular diseases, and certain mental disorders may be laid in early life. Some of the chronic orthopaedic ailments of the adult are probably connected with anomalies in the development or minor uncorrected inanities of the infant (e.g. talipes, congenital dislocation of the hip). Many of the measures subsequently undertaken to treat these disorders often do not fully succeed.

Since young children are "vulnerable" to social and health hazards which can retard or arrest their physical and mental development during these critical years, they deserve special attention by the administration, general population and the family.

CHILD HEALTH PROBLEMS

The problems facing the health worker in the developing world are vast and are nowhere more evident than in the field of childcare. The main health problems encountered in the child population comprise the following:

1. Low birth weight
2. Malnutrition
3. Infections and parasitosis
4. Accidents and poisoning
5. Behavioural problems.

1. Low birth weight

This has been discussed in detail earlier.

2. Malnutrition

Malnutrition is the most widespread condition affecting the health of children. Scarcity of suitable foods, lack of purchasing power of the family as well as traditional beliefs and taboos about what the baby should eat, often lead to an insufficient balanced diet, resulting in malnutrition. A childhood mortality study in the Americas showed that no less than 50 per cent of the children who died before the age of 5 years were found to have malnutrition as underlying or
associated cause of death, the peak of this mortality being in the post-neonatal period. During 2006–12, more than 15 per cent of the world’s children under the age of 5 years were underweight for their age. The proportion ranged from 1.4 per cent of children in developed countries to 24 per cent in developing countries [28]. In India, the National Family Health Survey (NFHS) 2005–06 included survey of the nutritional status of young children. Both chronic and acute undernutrition were widespread and to be high in all the 7 states for which reports have been received, namely, Haryana, Karnataka, Maharashtra, Orissa, Tamil Nadu, Uttar Pradesh and West Bengal. At present in India 43.5 per cent of children under 5 years age are underweight. This includes 43 per cent moderate to severe cases, 15 per cent severe malnutrition, of these, 20 per cent have moderate to severe wasting and 48 per cent moderate to severe stunting [58].

Malnutrition makes the child more susceptible to infection, recovery is slower and mortality is higher. Unfed-and-favoured children do not grow to their full potential of physical and mental abilities. Malnutrition in infancy and childhood leads to stunted growth. It also manifests by clinical signs of micronutrient and vitamin deficiencies. Prevention and appropriate treatment of diarrhoea, measles and other infections in infancy and early childhood are important to reduce malnutrition rates as infection and malnutrition often make vicious cycle. Exclusive breast-feeding in first 6 months of life is very important.

Specific nutritional deficiencies

(a) Protein-energy malnutrition

Protein-energy malnutrition (PEM) is defined as a major public health problem in India. It occurs particularly in weaklings and children in the first years of life. It is characterized by low birth weight if the mother is malnourished, poor growth in children and a high level of mortality in children between 12 and 24 months, and is estimated to be an underlying cause in 30 per cent of deaths among children under age 5.

As many as 37 per cent of the children in the developing world have low height for their age i.e. stunting, and 30 per cent children have low weight for height. The rate of low height for age reflects the cumulative effects of undernutrition and infections since birth or even before birth; high rates are often suggestive of bad environmental conditions and/or early malnutrition. On the other hand, a greater frequency of low weight for height, often reflects current severe undernutrition or disease.

(b) Micronutrient malnutrition

Micronutrient malnutrition refers to a group of conditions caused by deficiency of essential vitamins and minerals such as vitamin A, calcium, iodine, iron and zinc. It is estimated that about 2 billion people are affected by this type of malnutrition. Vitamin A deficiency is the most common cause of preventable childhood blindness worldwide; iodine deficiency causes goitre, cretinism and brain damage; and anaemia results from insufficient iron intake.

Nutritional anaemia: It affects all age groups, including pre-school children, school children and elders. Even mild anaemia reduces resistance to fatigue. It has a profound effect on psychological and physical behaviour.

Vitamin A deficiency and nutritional blindness: Young children are at greater risk of developing xerophthalmia, partly because their vitamin A requirements are proportionately greater than those of any other group and partly because they suffer most from infections. The result is that severe, blinding corneal destruction is most frequently seen in children between the age of six months and six years. Vitamin A deficiency is in fact, the single most frequent cause of blindness among pre-school children in developing countries. Some 20 per cent children with this deficiency are at increased risk of death from common infections, and around 2 per cent are blinded or suffer serious sight impairment.

Iodine deficiency: Iodine deficiency disorders pose a public health problem in which 1.5 billion people are living in environments lacking this mineral. As a result at least 30,000 babies are stillborn each year and over 120,000 are mentally retarded, physically stunted, deaf-mute or paralyzed. Even when children are born otherwise healthy, lack of iodine may still cause mental dullness and apathy.

The nutritional deficiencies not only lead to severe illnesses, entailing long and costly treatment, but also influence physical development, psychological and susceptibility to infection.

3. Infectious and parasitic disease

Young children fall an easy prey to infectious diseases. The leading childhood diseases are: diarrhoea, respiratory infections, measles, pertussis, polio, neonatal tetanus, tuberculosis, and diphtheria. It is known that a child may get affected several times in a year; the incidence increases with the aggravation of a state of malnutrition. Of about 4 million deaths a year from acute respiratory infections in the developing world, a quarter are linked to malnutrition, and a further quarter associated with complications of measles, pertussis, malaria and HIV/AIDS. During 2012, about 9 per cent of under-five mortality worldwide was due to diarrhoeal diseases, about 17 per cent due to ARIs, about 1 per cent deaths were due to measles and about 7 per cent due to malaria. In India, during the year 2013, 4,090 cases of diphtheria, 15,768 cases of measles, 36,661 cases of pertussis, and 528 cases of neonatal tetanus were reported (59). The actual figures may be several times higher since there is considerable under-reporting. This is so, for example, in the case of eruptive fevers, malaria, influenza, meningitis and various gynaecological infections and amebiasis etc. which are common because of poor environmental sanitation and paucity of potable drinking water. The nutritional deficiencies not only lead to severe illnesses but may interrupt the transmission of infection in the community.

These few facts, which are merely examples and could be multiplied, show that the prevention and treatment of infections and parasitism of children is bound to have important long-term consequences.

4. Accidents and poisoning

In the developed world, accidents and poisoning have become a relatively more important child health problem. There is every reason to believe that accidents among children are frequent in the developing countries also, especially burns and trauma as a result of home accidents and, to an increasing degree, traffic accidents. Children and young adolescents are particularly vulnerable to domestic accidents — including falls, burns, poisoning and drowning.
5. Behavioural problems

Behavioural disturbances are notable child health problems, the importance of which is increasingly recognized in most countries. Children abandoned by their families present severe social and health problems. Over 60,000 children are abandoned each year in India (60).

6. Other factors affecting the health of children

a. Maternal health

A major determinant of child health is the health of his/her mother. Child health is adversely affected (the risk begins even before birth) if the mother is malnourished, if she is under 18 years (too young) or over 35 (too old), if her last child was born less than 2 years ago (too close), if she has already more than 4 births (too many) and if she is deprived of basic pregnancy care. A healthy mother brings forth a healthy baby, with better chances of survival.

b. Family

In pre-school years, the child is very much an organic part of the immediate family. Whatever happens to him or her affects the other members of the family, and vice versa. Therefore, “child health” has to be “family health”. It depends upon the family’s physical and social environment, which includes its lifestyle, customs, culture, traditional habits, and the childrearing and childbearing practices are greatly influenced by this. The family and social environment has a considerable influence on the development of speech, personality and the intellectual potentials of the small child. Other factors are the family size, the family relationships, and family stability. Infancy and early childhood is the time when the child contracts common contagious illness from contact with others (older brothers and sisters, playmates, school-mates). Data shows that the number of episodes of infectious diarrhoea increases with the size of the family. Studies also show an increase in the prevalence of malnutrition in families with more than 4 children. In short, fewer children would mean better nutrition, better health care, less morbidity and lower infant mortality.

c. Socio-economic circumstances

The socio-economic situation in which the family is placed is a very important factor in child health. In every region of the world, the physical and intellectual development of children varies with the family’s socio-economic level. Under-privileged children of the same age are smaller, lighter and less advanced in psychomotor and intellectual performance, compared to children of privileged group. A detailed analysis of socio-economic factors shows the ‘part played by the parents’ education, profession and income, their housing, the urban or rural, industrialized or non-industrialized nature of the population.

Poverty, illiteracy (especially mothers’ illiteracy) and sickness create a vicious circle starting from one generation to the next, and from which it is difficult for the individual to escape. The differences in health between rich and poor, which can be observed in all age-groups are particularly striking among children.

d. Environment

After the first week of a child’s life, the environmental factors play a very great role as determinants of infant and childhood mortality and morbidity. Tetanus infection of the newborn may take a heavy toll of the newborn in the first few weeks of life. Diarrhoea, pneumonia and other infections, tetanus, and malnutrition are extremely common in children exposed to insanitary and hostile environment. The stages at which these infections occur vary according to ecological conditions, home and family hygiene, local epidemiological conditions and the extent to which they come into contact with earth, water and animal excreta. Much of the contamination supply of safe water, inadequate disposal of human excreta and other waste, an abundance of insects and other disease vectors are essentially environmental factors continuously menacing family health.

Another important factor which influences child development is environmental stress thus, a parent also develop skills if they are given the opportunity. Stimulation, particularly the interaction with people who take interest early in life, helps children to develop. Other sources of environmental stimulation are the radio, TV and illustrated magazines.

e. Social support and health care

Other factors affecting the health status of children include community and social support measures, ranging from creches and day care facilities to organized health care systems.

RIGHTS OF THE WOMEN AND CHILDREN

Women and children are the most vulnerable section of the society. It is, therefore, vital to improve their health and well-being in order to achieve complete development of overall human resources.

One of the core functions assigned to the WHO in its Constitution of 1948 was to "promote maternal and child health and welfare". By the 1990s, national health plans and policy documents from development agencies invariably stressed that mothers and children were vulnerable groups and, therefore, priority "targets" for public health action. The notion of mothers and children as vulnerable group was also central to the primary health care movement launched at Alma-Ata in 1978. The plight of mothers and children came to be seen as much more than a problem of biological vulnerability. The 1987 Cal to Action for Safe Motherhood explicitly framed it as "deeply rooted in the adverse social, cultural and economic environment of the society, and specially the environment that societies create for women". Women’s relative lack of decision-making power and their unequal access to employment, finances, education, basic health care and other resources are considered to be the root causes of their ill-health, and that of their children. The unfairness of this situation has made it obvious that the health of mothers and children is an issue of rights, entitlements and day to day struggle to secure these entitlements. The milestones in this establishment of the rights of women and children are as shown in Fig. 9 (6)).

RIGHTS OF THE CHILD

One of the most encouraging signs of our times is the awareness of the public to the needs and rights of children. The needs of children and our duties towards them are enshrined in our Constitution; the relevant articles are:

a. Article 24 prohibits employment of children below the age of 14 in factories;
The Universal Declaration of Human Rights states that ‘motherhood and childhood are entitled to special care and assistance’, 1948.

The Convention on the Elimination of All Forms of Discrimination Against Women enjoins States parties to ensure appropriate maternal health services. 1981.

At the United Nations World Summit on Children, governments declare their ‘joint commitment... to give every child a better future’, and recognize the link between women’s rights and children’s well-being. 1995.

The United Nations Human Rights Committee rules that, when abortion gives rise to a criminal penalty even if a woman is pregnant as a result of rape, a woman’s right to be free from inhuman and degrading treatment might be violated. 1996.

The United Nations Committee on the Rights of the Child states that adolescent girls should have access to information on the impact of early marriage and early pregnancy and have access to health services sensitive to their needs and rights. 2003.

The United Nations Committee Against Torture calls for an end to the extraction or confession for prosecution purposes from women seeking emergency medical care as a result of illegal abortions. The United Nations Special Rapporteur on the Right to Health reports that all forms of sexual violence are inconsistent with the right to health. 2004.

FIG. 9

Milestones in the establishment of the rights of women and children

b. Article 39 prevents abuse of children of tender age, and

c. Article 45 provides for free and compulsory education for all children until they complete the age of 14 years.

In the country’s Five Year Plans, special attention has been given to the welfare of children particularly the weaker sections. Various schemes have been introduced and implemented to achieve this goal. However, despite constitutional provisions, organized efforts for stepping up child welfare services did not take place until 1959.

UN DECLARATION OF THE RIGHTS OF THE CHILD

The year 1959 ushered in a new era in child welfare. To meet the special needs of the child, the General Assembly of the United Nations adopted on 20th November 1959, the Declaration of the Rights of the Child. India was a signatory to this Declaration. The Rights of the Child are:

1. Right to develop in an atmosphere of affection and security and, wherever possible, in the care and under the responsibility of his/her parents.

2. Right to enjoy the benefits of social security, including nutrition, housing and medicare.

3. Right to free education.

4. Right to full opportunity for play and recreation.

5. Right to a name and nationality.

6. Right to special care, if handicapped.

7. Right to be among the first to receive protection and relief in times of disaster.

8. Right to learn to be a useful member of society and to develop in a healthy and normal manner and in conditions of freedom and dignity.

9. Right to be brought up in a spirit of understanding, tolerance, friendship among people, peace and universal brotherhood and
dignity.

10. Right to enjoy these rights, regardless of race, colour, sex, religion, national or social origin.

UNIVERSAL CHILDREN’S DAY

November 14 is observed as Universal Children’s Day. It was started by the International Union for Child Welfare and
the UNICEF. In 1954, the UN General Assembly passed a formal resolution establishing Universal Children’s Day and assigned to UNICEF the responsibility for promoting this annual day.

A non-governmental organization (Defence for Children International, Geneva) was set up in 1979 (during the International Year of the Child) to ensure ongoing, systematic international action specially directed towards promoting and protecting the Rights of the Child.

The 1990 World Summit for children agreed on a series of specific social goals for improving the lives of the children including measurable progress against malnutrition, preventable diseases and illiteracy. The vital vulnerable years of childhood should be given a first call on society’s concerns and capacities. A child has only one chance to develop normally, and the protection of that one chance, therefore, demands the kind of commitment that will not be superseded by other priorities. The following are the goals that have been accepted by almost all nations.

**Social goals for the year 2000 (62)**

The end-of-century goals agreed to by the nations following the 1990 World Summit for children were:

1. A one-third reduction in 1990 under-five death rates (or to 70 per 1000 live births, whichever is less)
2. A halving of 1990 maternal mortality rates
3. A halving of 1990 rates of malnutrition among the world’s under-five (to include the elimination of micronutrient deficiencies, support for breast-feeding by all maternity units, and a reduction in the incidence of low birth weight to less than 10 per cent)
4. Achievement of 90 per cent immunization among under-fives, eradication of polio, elimination of neonatal tetanus, a 90 per cent reduction in measles cases and a 95 per cent reduction in measles deaths (compared to pre-immunization level)
5. A halving of child deaths caused by diarrhoeal disease
6. A one-third reduction of child deaths from acute respiratory infections
7. Basic education for all children and completion of primary education by at least 80 per cent girls as well as boys
8. Clean water and safe sanitation for all communities
9. Acceptance in all countries of the Convention on the Rights of Child, including improved protection for children in especially difficult circumstances; and
10. Universal access to high quality family planning information and services in order to prevent pregnancies that are too early, too closely spaced, too late or too many.

**NATIONAL POLICY FOR CHILDREN**

Keeping in view the constitutional provisions and the United Nations Declaration of the Rights of the Child, the Government of India adopted a National Policy for Children in August 1974. The Policy declares:

*It shall be the policy of the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development. The State shall progressively increase the scope of such services so that, within a reasonable time, all children in the country enjoy optimal conditions for their balanced growth.*

According to the Declaration, the development of children has been considered an integral part of national development. The Policy provides that “the child is a nation’s supreme asset” and declares that the nation is responsible for their “nurture and solicitude”. It further spells out various measures to be adopted and priorities to be accorded to children’s programmes with a focus on areas like child health, child nutrition and welfare of the handicapped and destitute children.

A high level National Children’s Board with the Prime Minister as Chairman was established. It provides a forum where problems relating to child welfare and their purposeful development into useful members of society are evolved, reviewed and coordinated into an effective programme (68).

Following the enunciation of the National Policy for Children, a number of programmes were introduced by the Government of India, viz. the ICDS Scheme, programmes of supplementary feeding, nutrition education and production of nutritious food, constitution of the “National Children’s Fund” under the Charitable Endowments Act, 1980, institution of National Awards for Child Welfare, Welfare of the Handicapped (63).

**Review of existing policies and legislations (64)**

The Constitution of India follows the principle of protective discrimination and thereby commits itself to safeguard the rights of children through policies, laws and action. These commitments are reflected through the policies which are as follows:

1. National Policy for Children, 1974 provides the conceptual basis for an integrated approach to address the whole child and commits the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development.
2. National Policy on Education, 1986 and its National Plan of Action, which has a full section on early childhood care and education. It clearly recognizes the holism of nurturing the child; and that ECCE is the crucial foundation for human resource development and cumulative lifelong learning. It is viewed as a feeder and support programme for universal elementary education – especially for first generation learners, and an important support service for working mothers and girls.
3. The National Children’s Fund was created during the international year of the child in 1979 under the Charitable Endowment Fund Act, 1890. The fund provides financial assistance to voluntary agencies for implementing programmes for the welfare of children including rehabilitation of destitute children.
4. National Health Policy, 2002 accords primacy to preventive and first line curative care at primary health level, and emphasizes convergence, and strategies to change care behaviours in families and communities.
5. National Charter for Children, 2003 intends to secure for every child its inherent right to be a child and enjoy a healthy and happy childhood, to address the
root causes that negate the healthy growth and development of children, and to awaken the conscience of the community in the wider societal context to protect children from all forms of abuse, while strengthening the family, society and the nation.

The national charter for children affirms India's commitment to the child. However, it does not declare India's acceptance of children's entitlements as their rights. The national policy for children, 1974 still stands as the official policy commitment to children of India. With India's accession to the UNCRHR and its two optional protocols, rights-based framework has been accepted as the guiding frame for policy measures and programming for children. This is clearly reflected in the national plan of action for children, 2005.

6. Commission for the Protection of Child Rights Act, 2005 provides for the constitution of a national commission and state commissions for protection of child rights and children's courts for providing speedy trial of offences against children or of violation of child rights and for matters connected therewith or incidental thereto.

7. National Plan of Action for Children, 2005 articulates clearly the rights, perspective, and agenda for the development of children. It provides a robust framework within which to promote the development and protection of children. The guiding principles of the NPA are:

   a. To regard the child as an asset and a person with human rights;
   b. To address issues of discrimination emanating from biases of gender, class, caste, race, religion and legal status in order to ensure equality;
   c. To accord utmost priority to the most disadvantaged, poorest of the poor and the least served child in all policy and programme interventions; and
   d. To recognize the diverse stages and settings of childhood, and address the needs of each, providing all children the entitlements that fulfill their rights and meet their needs in each situation.

Time targets in the NPAC 2005 extend to 2012, the end-year of the Eleventh Plan. The NPAC 2005 has identified 12 key priority areas for the highest and most sustained attention in terms of outreach, programme interventions and resource allocations. These are:

- Reducing infant mortality rate
- Reducing maternal mortality rate
- Reducing malnutrition among children
- Achieving 100% civil registration of births.
- Universalization of early childhood care and development and quality education for all children achieving 100% access and retention in schools, including pre-schools.
- Complete abolition of female foeticide, female infanticide and child marriage and ensuring the survival, development and protection of the girl child.
- Improving water and sanitation coverage in both rural and urban areas.
- Addressing and upholding the rights of children in difficult circumstances.
- Securing for all children all legal and social protection, from all kinds of abuse, exploitation and neglect.
- Complete abolution of child labour with the aim of progressively eliminating all forms of economic exploitation of children.
- Monitoring, review, and reform of policies, programmes and laws to ensure protection of child's inherent and rights.
- Ensuring child participation and choice in matters and decisions affecting their lives.

A new alienation of children from their rights has arisen with the plight of children affected by HIV/AIDS. Since the finalization of the NPAC the issues of these children have also been accepted as key priorities by MWCD and therefore found a place in the Eleventh Plan among critical concerns that need to be addressed.

8. Integrated Child Protection Scheme (ICPS) (655, 66)

During the year 2009-10, the Ministry of Women and Child Development launched a new centrally sponsored scheme called "Integrated Child Protection Scheme" (ICPS) with a view to create a safe and secure environment in the country for the comprehensive development of children who are in need of care and protection, children in conflict and in contact with law (either as a victim or as a witness or due to any other circumstances), children of migrant families, children of prisoners, prostitutes, working children, street children, trafficked or sexually exploited children, child drug abusers, child beggars etc.

The objectives of the scheme are: (1) Improve access to and quality of child protection services; (2) Raise public awareness about child rights; (3) Clearly articulated responsibilities and accountability for child protection; (4) Establish structures at all government levels for delivery of statutory and support services to children in difficult circumstances; and (5) Setting-up of an evidence based monitoring and evaluation system.

The services provided under ICPS are as follows:

1. Emergency outreach service through 'Child line', dedicated number is 1098. It is a 24-hour toll free telephone service available to all children in distress.
2. Open shelters for children in need, in urban and semi-urban areas.
3. Family based non-institutional care through sponsorship, foster-care, adoption, cradle baby centres and after-care.
4. Institutional services through shelter homes, children homes, observation homes, special homes and specialized services for children with special needs.
5. Web-enabled child protection management system including website for missing children.

The growing vulnerability of children in urban settlements, including those caught in the shifting frame of migratory and transient labour are also now in the MWCD portfolio. Their distress and the difficult circumstances of their childhoods merit special measures of development and protection.

Goals and targets set by Government of India for child health under various national and international commitments are as follows (64):
CHILD HEALTH GOALS/TARGETS

Common Minimum Programme
To raise public spending on health to at least 2.5% of GDP over the next five years and focus on primary health care... special attention will be paid to the poorer sections in the matter of health care.

Eleventh Five Year Plan 2007-12
Reduction of infant mortality rates to 28 per thousand live births by 2012. To raise the sex ratio for age group 0-6 from 927 in 2001 to 950 by 2011-12 and to 950 by 2016-17.

National Plan of Action for Children, 2005
- To reduce infant mortality rate to below 30 per 1000 live births by 2010.
- To reduce child mortality rate to below 51 per 1000 live births by 2010.
- To reduce neonatal mortality rate to below 18 per 1000 live births by 2010.
- To explore possibilities of covering all children with plan for health insurance.

Millennium Development Goals (MDG)
- Reduce by two-thirds, between 1990 and 2015, the under-five mortality rate (Goal 4).
- Reduce by three-quarters, between 1990 and 2015, the maternal mortality rate.
- Combat HIV/AIDS, malaria and other diseases.

National Health Policy, 2002
- To achieve an acceptable standard of good health among the population by increasing access to decentralized public health system and by establishing or upgrading the infrastructure in the existing institutions.
- Reduce IMR to 30/1000 and MMR to 100/kish by 2010.
- Eradicate polio and yaws, and eliminate leprosy by 2005.
- Improve nutrition and reduce proportion of LBW babies from 30% to 10% by 2010.
- Reduce mortality by 50% on account of TB, malaria and other vector and water-borne diseases by 2010.
- Reduce prevalence of blindness to 0.5% by 2010.

DELIVERING THE MCH SERVICES
MCH (mother and child health) is not a new specialty. It is a method of delivering health care to special group in the population which is especially vulnerable to disease, disability or death. These groups (i.e., children under the age 5 years and women in the reproductive age group (15-44 years) comprise about 32.4 per cent of the total population in India.

The MCH services encompass the curative, preventive and social aspects of obstetrics, paediatrics, family welfare, nutrition, child development and health education. The specific objectives of MCH are:
1. reduction of morbidity and mortality rates for mothers and children.
2. promotion of reproductive health, and
3. promotion of the physical and psychological well-being of the child within the family.

Through concern with child development and the health education of parents and children, the ultimate objective of MCH services is life-long health.

Sub-areas
The components of MCH include the following sub-areas:
- maternal health
- family planning
- child health
- school health
- handicapped children
- care of the children in special settings such as day care centres.

The content of MCH care will vary according to the demographic, social and economic patterns. Factors such as urbanization, rural migration, changing patterns of women's work and status have far-reaching effects on childbearing and child-rearing. It is now generally accepted that the MCH services should always be flexible and based on, and adapted to the local needs and resources of the community it serves; they should be moulded to the local traditions, cultures and other environmental characteristics and cannot be modelled on patterns copied from other countries. Health care, social legislation and social support measures also will have to be adapted to these changing needs and problems of the community.

MCH care is now conceived of as all activities which promote health and prevent or solve health problems of mother and children, irrespective of whether they are curative, diagnostic, preventive or rehabilitative, and whether they are carried out in health centres or in the home by primary health care workers, traditional dais, or highly trained specialists.

Recent trends in MCH care
Maternal and child care was traditionally designed and provided in the form of vertical programmes with "standard" technical content based on models from a few developed countries. Applied in different socio-economic situations, such vertical programmes have been unable to provide more than minimum coverage because of their cost, and they have scarcely been of a kind to solve the priority problems of the majority of mothers and children. The emergence of some new concepts is now changing the organization and management of MCH care in increasing number of countries (67). These are discussed below:

1. Integration of care
Conventional MCH services tended to be fragmented into antenatal care, postnatal care, infant care, family planning etc. The various components were dealt with separately by different staff or departments. This approach has changed over the years. The trend now is an "integrated" approach. This integration is based on the fact that it is inconvenient for the mother to go to one place to receive care for herself,
to another for care for their children, and yet another for family planning services.

An integrated approach implies that all those involved in maternity care from the obstetrician down to the local dal, must work as a team. Obstetric and paediatric units should be closely linked so that services for the care of the mother and the child to the hospital and community be planned and reviewed insuring teaching and research. This approach helps to promote continuity of care as well as improve efficiency and effectiveness of MCH care.

2. Risk approach

A promising means of improving the coverage and efficacy of MCH care and family planning is the risk approach. This is a managerial tool for better use of scarce resources. It is based on the early detection of mothers and children with high-risk factors. All mothers and children with high risk factors are given additional and more skill and care including hospitalization, while at the same time essential care is provided for the rest of the mothers and children so that every one gets care appropriate to their need.

It is also possible to assess the "degrees" of risk by each factor, by scoring according to their (a) magnitude — i.e., extent and severity; (b) treatability — responsiveness to treatment and control; (c) cost-effect — in terms of alleviating human suffering; and (d) community attitude — social concern. Such an approach when applied on a community-wide basis enables the determination of priority activities, within the MCH programme based on the "degrees" of risk.

Application of the risk approach to the problems of mothers and children is a departure from past or traditional practices to promote the health of mothers and children.

3. Manpower changes

The special category of "maternal and child health worker" (e.g., auxiliary-nurse-midwives, health visitors) at the peripheral level is gradually being phased out. A wide range of workers are now considered necessary for maternal and child health work. They include:

(i) Professionals: Specialists
(ii) Field workers: Multi-purpose workers, Health Guides, dais (traditional birth attendants), bakwiyaks, Anganwadi workers, extension workers, ASHA etc.
(iii) Volunteer workers: Members of women's organizations

Taking for example, the local dais in the past were not generally recognized by the national health authorities, who thought that their services were inimical to the safety of the mother and child. The current trend is to assist them perform safe deliveries through training and supervision. In India, where 70 percent of population lives in rural areas, there are not enough obstetricians to attend to all deliveries. Therefore, a trained dai or midwife is absolutely essential in every village. The same thing can be said about paediatrics. It is now recognized that obstetric and paediatric services can only be improved by cooperation and liaison with these practitioners.

4. Primary health care

Primary health care is now recognized as a way of making essential health care available to all. It has all the elements necessary to make a positive impact on the health of mothers and children. I.e., MCH care, family planning, control of infections, education about health problems and how to prevent them, and measures to ensure nutritious food — all closely related. Primary health care emphasizes family oriented care and support, and community self-reliance in health matters. MCH care is an indispensable priority element of primary health care in every country.

**Targets for MCH Services**

From time to time Government of India has suggested MCH goals with quantifiable time bound targets for achievement. Table 11 shows the MCH indicators with their goal period and the current level of achievement.

**Organisation of MCH/FP services**

The mother and child health, and family planning services were integrated in the Fourth Five Year Plan for better effectiveness. They both are now an integral part of primary health care, which places emphasis on community participation and sectoral coordination. The National Health Policy 2002 and National Population Policy 2000 has

Source: (7)
provided the necessary directives for reorienting and restructuring the health services, based on primary health care approach with short and long-term goals.

The infrastructure in rural areas is based on the complex of community health centres, primary health centres and their subcentres. They provide preventive and promotive health care services. Since deliveries by trained health personnel are crucial in reducing maternal and infant mortality in rural areas, the government of India undertook a scheme to train local dais to conduct safe deliveries. These dais are now available in most villages. Mention must be made of ICDS (Integrated Child Development Services) projects which are functioning all over the country providing a package of basic health services (eg. supplementary nutrition, immunization, health check-up, referral, nutrition and health education, and non-formal education services) to mother and children.

Maternal health care was a part of family welfare programme from its inception. Interventions were introduced on vertical schemes, but family planning remained a separate intervention. In 1992, the Child Survival and Safe Motherhood Programme integrated all the schemes for better compliance. More recently, Reproductive and Child Health Programme was launched in 1997, which integrated family planning, Child Survivals and Safe Motherhood Programme. Preventive management of STD/RTI, AIDS, and a client approach to health care. This programme has entered into phase II, with reorientation to make it consistent with the requirement of the National Rural Health Mission.

In urban areas, the general trend is towards institutional delivery. In larger cities, almost 90 per cent of deliveries take place in maternity hospitals and maternity homes. Some of the institutions are under the auspices of the Municipal Corporations and voluntary organizations. The services of obstetricians are available at district hospitals, which are the apical hospitals for MCH care at the district level. For specialized care of children, paediatric units have been established in several district hospitals.

Table 12 shows the evolution of maternal and child health programmes in India.

**INDICATORS OF MCH CARE**

Maternal and child health status is gauged through measurements of mortality, morbidity and growth and development. In many countries, mortality rates are still the only source of information. Morbidity data are scarce and poorly standardized. In recent years, attention has been paid to systematizing the collection, interpretation and dissemination of data on growth and development. The commonly used mortality indicators of MCH care are:

1. Maternal mortality ratio
2. Mortality in infancy and childhood
   a. Perinatal mortality rate
   b. Neonatal mortality rate
   c. Post-neonatal mortality rate
   d. Infant mortality rate
   e. 1-4 year mortality rate
   f. Under-5 mortality rate
   g. Child survival rate.

**MATERNAL MORTALITY RATIO**

According to WHO, a maternal death is defined as "the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental causes." (69)

Maternal mortality ratio measures women dying from "puerperal causes" and is defined as:

\[
\text{Maternal mortality ratio} = \frac{\text{Number of female deaths due to complications of pregnancy, childbirth or within 42 days of delivery from "puerperal causes" in an area during a given year}}{\text{Average annual number of live births in the same area and year}} \times 1000 \text{ (or 100,000)}
\]

Late maternal death: Complications of pregnancy or childbirth can also lead to death beyond the six-weeks postpartum period. In addition, increasingly available modern life-sustaining procedures and technologies enable more women to survive adverse outcomes of pregnancy and delivery, and to delay death beyond 42 days postpartum. Despite being caused by pregnancy-related events, these deaths do not count as maternal deaths if routine civil registration system. An alternative concept of late maternal death was included in ICD-10, in order to capture these delayed deaths that occur between six weeks and one year postpartum. It is defined as "the death of a women from direct or indirect causes, more than 42 days but less than one year after termination of pregnancy." (69)

Pregnancy-related death: A pregnancy-related death is the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the cause of death (33).

**Statistical measures of maternal mortality**

(a) Maternal mortality ratio : Number of maternal deaths in a given time period per 100,000 live births during the same time-period.

(b) Maternal mortality rate : Number of maternal deaths in a given period per 100,000 women of reproductive age during the same time-period.

(c) Adult lifetime risk of maternal death : The probability
PREVENTIVE MEDICINE IN OBSTETRICS, PAEDIATRICS AND GERIATRICS

of dying from a maternal cause during a woman's reproductive lifespan.

(a) The proportion of maternal deaths of women of reproductive age (PM) : The number of maternal deaths in a given time period divided by the total deaths, among women aged 15–49 years.

The International Classification of Diseases (ICD) has recommended that maternal deaths may be disaggregated into two groups:

(1) Direct obstetric deaths : those resulting from obstetric complications of the pregnant state (pregnancy, labour and ्xperium), from intervention, omissions, incorrect treatment, or from a chain of events resulting from any of the above.

(2) Indirect obstetric deaths : those resulting from previous existing disease or disease that developed during pregnancy and which was not due to direct obstetric causes, but which was aggravated by physiological effects of pregnancy.

The maternal mortality rate, the direct obstetric rate and the indirect obstetric rate are fine measures of the quality of maternity services.

The 43rd World Assembly in 1990 adopted the recommendation that countries consider the inclusion on death certificates of questions regarding current pregnancy and pregnancy within one year preceding death in order to improve the quality of maternal mortality data and provide alternative methods of collecting data on deaths during pregnancy or related to it, as well as to encourage the recording of deaths from obstetric causes occurring more than 42 days following termination of pregnancy.

Approaches for measuring maternal mortality

In the absence of complete and accurate civil registration systems, MMR estimates are based upon a variety of methods:

(1) Civil registration systems : This approach involves routine registration of births and deaths. Ideally, maternal mortality statistics should be obtained through civil registration data.

(2) House-to-house survey : Where civil registration data are not available, house-to-house survey provides an alternative.

(3) Sisterhood methods : Sisterhood methods obtain information by interviewing a representative sample of respondents about the survival of all their adult sisters (to determine the number of ever married sisters, how many are alive, how many are dead, and how many died during pregnancy, delivery, or within six weeks of pregnancy.

(4) Reproductive-age mortality studies (RAM0S) : This approach involves identifying and investigating the causes of all deaths of women of reproductive age in a defined area and using multiple sources of data.

(5) Verbal autopsy : This approach is used to assign cause of death through interview with family or community members, where medical certification of cause of death is not available. Records of births and deaths are collected periodically among small populations, under demographic surveillance systems maintained by the research institutions in developing countries.

(6) Census : A national census, with the addition of a limited number of questions, could produce estimates of maternal mortality; this approach eliminates sampling errors and hence allows a more detailed breakdown of the results, including time trends, geographic subdivisions and social strata.

Incidence

WORLD SCENARIO

Globally, an estimated 289,000 maternal deaths occurred in 2013, a decline of 47 per cent from levels in 1990. Sub-Saharan Africa (60 per cent) and South Asia (24 per cent) accounted for 86 per cent (249,000 maternal deaths) of the global burden in 2013. At the country level, two countries account for a third of global maternal deaths: India at 17 per cent (50,000) and Nigeria at 14 per cent (40,000). The global MMR in 2013 was 210 maternal deaths per live birth. The MMR in developing regions (250) was 15 times higher than in developed regions. Sub-Saharan Africa had the highest MMR at 510 maternal deaths per live births, three times the developed regions at 33 maternal deaths per live births (1).

A woman is most vulnerable at the post-partum period. About 50–70 per cent of maternal deaths occur in the postpartum period of which 45 per cent deaths occur in the first 24 hours after delivery and more than two-thirds during the first week. Between 11–17 per cent of maternal deaths occur during child birth itself (69).

Maternal mortality ratios strongly reflect the overall effectiveness of health systems, which in many low-income developing countries suffer from weak administrative, technical and logistical capacity, inadequate financial investment and a lack of skilled health personnel. Scaling up key interventions – for example, increasing the number of births attended by skilled health personnel, providing access to emergency obstetric care when necessary and providing post-natal care for mothers and babies – could sharply reduce both maternal and neonatal deaths. Enhancing women’s access to family planning, adequate nutrition, improved water and sanitation and reproducible basic health care and protection from abuse, violence, discrimination, empowerment of women, greater involvement of men in maternal and child health will also help. Women’s health care is still. These are not impossible, impractical actions, but proven, cost-effective provisions that women of reproductive age have a right to expect.

The low status of women in the society coupled with their low literacy levels prevent the women from taking antenatal care, does not have a right to expect. Women’s health care is still. These are not impossible, impractical actions, but proven, cost-effective provisions that women of reproductive age have a right to expect.

The low status of women in the society coupled with their low literacy levels prevent the women from taking antenatal care, does not have a right to expect. Women’s health care is still. These are not impossible, impractical actions, but proven, cost-effective provisions that women of reproductive age have a right to expect.
Maternal mortality ratio deliveries conducted by skilled personnel, antenatal care coverage and lifetime risk of maternal deaths in some developing and developed countries.

Source: (1, 7)

Maternal health, however, goes beyond the survival of pregnant women and mothers. For every woman who dies from causes related to pregnancy or childbirth, it is estimated that there are 20 others who suffer pregnancy-related illness or experience other severe consequences. The number is striking: An estimated 10 million women annually who survive their pregnancies experience such adverse outcomes.

Causes

Maternal deaths mostly occur from the third trimester to the first week after birth (with the exception of deaths due to complications of abortion). Studies show that mortality risks for mothers are particularly elevated within the first two days after birth. Most maternal deaths are related to obstetric complications including postpartum haemorrhage, infections, eclampsia and prolonged or obstructed labour - and complications of abortion. Most of these direct causes of maternal mortality can be readily addressed if skilled health personnel are on hand and key drugs, equipment and referral facilities are available.

About 80 per cent of maternal deaths are due to direct causes i.e. obstetric complications of pregnancy, labour and puerperium to interventions or incorrect treatment. As shown in Fig. 10 the single most common cause-accounting for a quarter of all maternal deaths - is obstetric haemorrhage, generally occurring postpartum which can lead to death very rapidly in the absence of prompt life-saving care.

Puerperal infections, often the consequence of poor hygiene during delivery, or untreated reproductive tract infections account for about 15% of maternal mortality. Such infections can be easily prevented. Hypertensive disorders of pregnancy, particularly eclampsia (conjunctions), result in about 13% of all maternal deaths. They can be prevented through regular blood pressure monitoring during pregnancy and treatment with relatively simple anticonvulsant drugs in cases of eclampsia.

Of the estimated 210 million pregnancies that occur every year, about 42 million end in induced abortion, of which only approximately 60 per cent are carried out under safe conditions. More than 20 million induced abortions each year are performed by people lacking the necessary skills or in an environment lacking the minimal medical standards, or both.

Around 8% of maternal deaths occur as a result of prolonged or obstructed labour. Other direct causes include ectopic pregnancies, embolism and deaths related to infection. Around 20 per cent of maternal deaths are due to indirect causes, that is, the result of pre-existing diseases or disease that developed during pregnancy, which are not due to direct obstetric cause but are aggravated by the physiological effect of pregnancy. One of the most significant is anaemia, which can cause death. Maternal anaemia affects about half of all pregnant women. Pregnant adolescents are more prone to anaemia than older women, and they often receive less care. Infectious diseases such as malaria, and intestinal parasites can exacerbate anaemia, as can poor quality diet - all of which heighten vulnerability to maternal death. Severe anaemia contributes to the risk of death in cases of sepsis. Other important causes of indirect death are hepatitis, cardiovascular diseases,
diseases of the endocrine and metabolic system and infections such as tuberculosis, malaria and increasingly HIV/AIDS (71). Each year, approximately 50 million women living in malaria-endemic countries throughout the world become pregnant. Around 10,000 of these women die as a result of malaria (72).

Social correlates

A number of social factors influence maternal mortality. The important ones are: (a) Women's age: The optimal child-bearing years are between the ages of 20 and 30 years. The further away from this age range, the greater the risks of a woman dying from pregnancy and childbirth. (b) Birth interval: Short birth intervals are associated with an increased risk of maternal mortality. (c) Parity: High parity contributes to high maternal mortality.

Not only are these three variables interrelated, but there are also other factors which are involved, e.g., economic circumstances, cultural practices and beliefs, nutritional status, environmental conditions and violence against women. The social factors often precede the medical causes and make pregnancy and child-birth a risky venture.

INDIA

India is among those countries which have a very high maternal mortality ratio. According to the estimates the MMR has reduced from 212 per 100,000 live births in 2007-09 to 178 per 100,000 live births in 2010-12, a reduction of 34 points over a period of three years period. States of Kerala, Maharashtra and Tamil Nadu have already achieved the goal of a MMR of 100 per 100,000 live births. In EAG and Assam category of states, MMR is about 257 per 100,000 live births, with Assam on top (328) and Uttar Pradesh (292), Rajasthan (255), Madhya Pradesh (250), Odisha (230) closely following. Assam, Madhya Pradesh and Rajasthan have shown an acceleration in reduction in last three years (73).

During the year 2012, about 47,000 women died of pregnancy related causes (74). It is mainly due to large number of deliveries conducted at home by untrained persons. In addition, lack of adequate referral facilities to provide emergency obstetric care for complicated cases also contribute to high maternal morbidity and mortality.

From year 2000 onwards, SRS (Central registration system) included a new method called the "RHIME" or Representative, Re-sampled, Routine Household Interview of Mortality with Medical Evaluation. This is an enhanced form of "verbal autopsy" which is the key feature of a prospective study of 1 million deaths within the SRS. RHIME include random re-sampling of field-work by an independent team for maintaining quality of data. For comparability with WHO estimates for India and for other countries, the WHO's "Global Burden of Disease" categorization of maternal deaths has been used, which includes various categories with their ICD-10 codes such as: haemorrhage, sepsis, hypertensive disorder, obstructed labour, abortion, and other conditions.

The SRS report has been grouped into three categories; (a) EAG states of Bihar and Jharkhand, Madhya Pradesh and Chhattisgarh, Orissa, Rajasthan, Uttar Pradesh and Uttrakhand and Assam. These states have high mortality indicators; (b) This category includes southern states of Andhra Pradesh, Karnataka, Kerala and Tamil Nadu. These states have comparatively lower health indicators; (c) The remaining states have been classified as others (73).

Table 14 shows live births, maternal deaths, maternal mortality in India from 2010-2012, special survey of deaths using RHIME. During this period the life time

risk of maternal death of women in the age group 15-49 has been reported to be 0.6 per cent. This is substantially higher for women in the category LAG states and Assam (1.0 per cent) compared to women in the category southern (0.3 per cent) or in the "other" states (0.4 per cent).

The age distribution of maternal and non-maternal deaths from the 2010-2012 Special Survey of Deaths are given in Table 15. It shows that more than two-thirds of the maternal deaths are of women in age group 20-34 years. In contrast, non-maternal deaths are more evenly distributed over the reproductive age span of 15-49 years.

**Causes**
The major causes of maternal mortality according to the 2001-2003 SRS survey are haemorrhage (38 per cent), sepsis (11 per cent), hypertensive (5 per cent), obstructed labour (5 per cent), abortion (8 per cent) and other causes (34 per cent). Anaemia (19 per cent) is not only one of the leading causes of maternal death. That this should continue despite MTP facilities points to the need for wider dissemination of information about these facilities. Induced abortions also point to a large unmet need for contraceptives, as with each pregnancy the woman faces increased risk of death. The percentage distribution of causes of maternal deaths during the year 2000-2003 are as shown in Fig. 11.

**FIG. 11**

**Obstetric causes**
- Toxaemia of pregnancy: Age at child birth
- Haemorrhage: Parity
- Infection: Too close pregnancies
- "Obstructed labour": Family size
- Unsafe abortion: Malnutrition
- Accidents: Depth

**Social factors**
- Ignorance and prejudices: Lack of maternity services
- shorter of health services: Delivery by untrained dais
- Associated illnesses, e.g., cardiac, renal, hepatic: Poor environmental sanitation
- Malnutrition: Transport facilities
- Accidents: Social customs, etc.

Newer approaches such as "risk approach" and primary health care are steps in the right direction to reduce maternal mortality and morbidity. Despite best antenatal care, some women may develop complications without warning signs and require emergency care. Essential obstetric care and establishment of first referral units (FRUs) for emergency obstetric care is, therefore, a high priority under the safe motherhood component of Reproductive and Child Health Programme. Equally important is an attack on social and cultural factors (e.g., ignorance, low levels of female literacy, prejudices inherent in the socio-cultural milieu, low levels of nutrition and poor environmental sanitation). It calls for a concurrent development of the community through active community involvement.

**National maternal health care indicators**
The estimates of maternal mortality can only be used as a rough indicator of maternal health situation in any given country. Hence indicators such as antenatal check-up, institutional delivery and delivery by trained personnel etc. are used to assess the maternal health status. These indicators also reflect the status of the ongoing programs and interventions and the situation of maternal health (76). Table 17 shows the national average of key indicators as per different surveys conducted in India (76).

* Safe delivery is defined as institutional deliveries plus deliveries conducted at home by skilled staff and do not include deliveries by trained birth attendants (data).
Preventive and social measures

High maternal mortality reflects not only in inadequacy of health care services for mothers, but also a low standard of living and socio-economic status of the community. In the world as a whole, the problem of maternal mortality is principally one of applying existing obstetric knowledge through antenatal, intranatal and postnatal services rather than developing new skills. Any attempt to lower MMR must take into consideration the following measures:

1. Early registration of pregnancy.
2. At least four antenatal check-ups.
3. Dietary supplements, including correction of anaemia.
4. Prevention of infection and haemorrhage during parturition.
5. Prevention of complications, e.g., eclampsia, malpresentations, ruptured uterus.
6. Treatment of medical conditions, e.g., hypertension, diabetes, tuberculosis, etc.
7. Anti-malaria and tetanus prophylaxis.
8. Clean delivery practice.
9. In India, a large number of maternal deaths could be prevented with the help of trained local dais and female health workers.
10. Institutional deliveries for women with bad obstetric history and risk factors.
11. Promotion of family planning – to control the number of children to not more than two, and spacing of births.
12. Identification of every maternal death, and searching for its cause, and
13. Safe abortion services.

MORTALITY IN INFANCY AND CHILDHOOD

Mortality rates are good indicators to measure the level of health and health care in different countries. They also help in assessing the overall socio-economic development of a country and correlate well with certain economic variables such as GNP. Medical and social progress have substantially reduced mortality in childhood.

It has become customary to consider mortality in and around infancy in a number of time periods convenient from both the analytical and programmatic point of view as under:

- perinatal period
- early neonatal period
- late neonatal period
- neonatal period
- post neonatal period

These are as illustrated in Fig. 12.

FOETAL DEATH: Foetal death is death prior to the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy; the death is indicated by the fact that after such separation the foetus does not breathe or show any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles (77). Defined variously as death after the 20th or 28th week of gestation (the definition of length of gestation varies between countries).

![Infant mortality diagram](image)

Infant mortality diagram showing stages of infant mortality, including post-neonatal death, neonatal death, late neonatal death, early neonatal death, perinatal death, and stillbirth. The diagram is labeled with time periods: 28 weeks, 7 Days, 28 Days, 1 Year.

**FIG. 12**

Mortality in and around infancy

Some observers have expressed the view that vital statistical reports are less reliable on foetal deaths occurring at 20–27 weeks than on those occurring after 28 completed weeks, and have preferred to analyze the data separately for the two intervals. Stillbirths are seldom reported in developing countries.

Because of the above difficulties WHO has recommended that within any country the term “stillbirth” be applied to a foetus born dead, and weighing over 500 g – the birth weight most frequently associated with a gestation period of 22 weeks. But for international comparison, however, they suggested a boundary of 1000 g or more, which is more frequently associated with a gestation period of 28 weeks.

**STILLBIRTH RATE**

The most widespread use of the term is, “death of a foetus weighing 1000 g (this is equivalent to 28 weeks of gestation) or more” occurring during one year in every 1000 total births (live births plus stillbirths). Stillbirth rate is given by the formula:

\[
\text{Stillbirth rate} = \left( \frac{\text{Foetal deaths weighing over 1000 g at birth}}{\text{Total births}} \right) \times 1000
\]

It is a frequent occurrence in the developing countries. Its prevention involves the detection and treatment of infectious pathology in the course of pregnancy as well as of high blood pressure and its complications, Rh incompatibility, diabetes and premature rupture of the membranes. Some causes are difficult or impossible to eliminate, such as multiple pregnancies, cord anomalies, foetal malformations, placenta anomalies. Approximately 3.3 million babies are stillborn each year worldwide (72). In India, the SRS estimates for the year 2012 for the whole country is about 5 per 1000 total births (5 for the rural and 5 for the urban areas). Among the bigger
The estimates provided by Lancet Stillbirth Series for India is 22 per 1000 live births for the year 2009. This estimate is being used as a target-setting exercise by India Newborn Action Plan (launched in June 2014). With the current level of average annual rate of reduction, which is less than 1 per cent, India is expected to reach SGR of 15 per 1000 live births by 2030 (81).

PERINATAL MORTALITY RATE

As currently defined, the term "perinatal mortality" includes both late foetal deaths (stillbirths) and early neonatal deaths. The Eighth Revision of the International Classification of Diseases (ICD) defined the "perinatal period" as lasting from the 28th week of gestation to the seventh day after birth. The Ninth Revision (1978) of ICD added that:

i) Babies chosen for inclusion in perinatal statistics (this means late foetal deaths, live births and early neonatal deaths) should be those above a minimum birth weight, i.e., 1000 g at birth (a birth weight of 1000 g is considered equivalent to gestational age of 28 weeks)

ii) if the birth weight is not available, a gestation period of at least 28 weeks should be used, and

iii) where (i) and (ii) are not available, body length (crown to heel) of at least 35 cm should be used. But the preferred criterion is birth weight.

The Conference for the Tenth Revision (ICD-10) made no changes to these definitions.

### Definitions (79)

The WHO’s definition, more appropriate in nations with well-established vital records of stillbirths is as follows:

- Late foetal deaths (28 weeks gestation and more) + early neonatal deaths (first week) in one year

\[ \text{PMR} = \frac{\text{Live births} + \text{late foetal deaths}}{\text{28 weeks gestation and more}} \times 1000 \]

### The WHO’s definition, more appropriate in nations with well-established vital records, is:

- Late foetal deaths (28 weeks + of gestation) + postnatal deaths (first week) in one year

\[ \text{Perinatal mortality rate} = \frac{\text{Live births in a year}}{\times 1000} \]

There is a difference in denominator of the perinatal mortality rate defined by the WHO and industry-developed nations. This makes international comparisons difficult.

### International comparisons

For international comparisons, the WHO Expert Committee on the Prevention of Perinatal Mortality and Morbidity (1970) recommended a more precise formulation:

- Late foetal and early neonatal deaths weighing over 1000 g at birth, expressed as a ratio per 1000 live births weighing over 1000 g at birth

\[ \text{Late foetal and early neonatal deaths weighing over 1000 g at birth} \times 1000 = \text{Perinatal mortality rate} \]

Perinatal mortality rate

- Total live births weighing over 1000 g at birth

\[ \text{Total live births weighing over 1000 g at birth} \times 1000 = \text{Perinatal mortality rate} \]

### Why perinatal mortality rate?

With the decline of infant mortality rate to low levels in many developed countries, perinatal mortality rate has assumed greater significance as a yardstick of obstetric and paediatric care before and around the time of birth.

First, two types of death rate i.e., stillbirths and deaths under the first week of life are combined in perinatal mortality rate because the factors responsible for these two types of deaths are often similar, being those operating before and around the time of birth. Secondly, a proportion of deaths which occur after birth are incorrectly registered as stillbirths, thereby inflating the stillbirth rate and lowering the neonatal death rate. The perinatal mortality rate, being a combination of stillbirths and early neonatal deaths, is not influenced by this error, by removing from consideration the dividing line between a stillbirth and a live birth with death shortly after birth.

Although perinatal period occupies less than 0.5 per cent (less than 168 hours) of the average life span, there are more deaths within this period than during the next 30–40 years of life in many developing countries (80). The value of perinatal mortality rate is that it gives a good indication of the extent of pregnancy wastage as well as the quality and quantity of health care available to the mother and the newborn. It reflects the results of maternity care more clearly than the neonatal death rate.

### Incidence

Perinatal mortality is a problem of serious dimensions in all countries. It now accounts for about 90 per cent of all...
foetal and infant mortality in the developed countries. In India, stillbirths are seldom registered. Consequently, most studies on perinatal mortality in this country are hospital-based. The SRS estimates for perinatal mortality rate in India for the year 2010 was about 32 per 1000 live births and stillbirths, with about 35 for rural areas and 22 for the urban areas. The statewide perinatal mortality rate is shown in Table 18.

In developed countries, perinatal mortality rates have gradually declined during the past decades due to improved obstetric and perinatal technologies.

Social and biological variables

A number of social and biological factors are known to be associated with perinatal mortality. The degree to which these factors influence perinatal mortality varies from country to country. Many of these factors also endanger the life of the mother, causing high maternal mortality. An appreciation of these factors (at-risk factors) will certainly make the greatest impact on reducing perinatal mortality. The overall risk is increased in the following categories:

1. Low socio-economic status;
2. High maternal age (35 years or more);
3. Low maternal age (under 16 years);
4. High parity (fifth and subsequent pregnancies, especially with short intervals between pregnancies);
5. Heavy smoking (10 or more cigarettes daily);
6. Maternal height - short stature (as compared with average for locality);
7. Poor past obstetric history (one or more previous stillbirths and neonatal deaths, one or more premature live-born infants);
8. Malnutrition and severe anaemia;
9. Multiple pregnancy.

For further details see page 569 under factors affecting infant mortality.

Causes of perinatal mortality

About two-thirds of all perinatal deaths occur among infants with less than 2500 g birth weight. The causes involve one or more complications in the mother during pregnancy or labour, in the placenta or in the foetus or neonate.

Main causes: The main causes of death are intrapartum and birth asphyxia, low birth weight, birth trauma, and intrapartum or neonatal infections. The various causes of perinatal mortality may be grouped as below:

(a) Antenatal causes

1. Maternal diseases: hypertension, cardiovascular diseases, diabetes, tuberculosis, anaemia
2. Pelvic diseases: uterine myomata, hydrodometrosis, ovarian tumours
3. Anatomical defects: uterine anomalies, incompetent cervix
4. Endocrine imbalance and inadequate uterine preparation
5. Blood incompatibilities
6. Malnutrition
7. Toxoaemia of pregnancy
8. Antepartum haemorrhage
9. Congenital defects
10. Advanced maternal age

(b) Intrapartum causes

1. Birth injuries
2. Asphyxia
3. Prolonged effort time
4. Obstetric complications

(c) Postnatal causes

1. Prematurity
2. Respiratory distress syndrome
3. Respiratory and alimentary infections
4. Congenital anomalies

(d) Unknown causes

In some cases, the causes are not clinically ascertainable.

Interventions for the reduction of perinatal mortality

Measures to reduce perinatal mortality rates are essential to accelerate the declining trend in neonatal and infant mortality rates. For further details, refer to Table 21.

International certificate of perinatal death

For international comparability, the 9th (1975) Revision of International Classification of Diseases (ICD-9) recommended a special certificate of cause of perinatal death. The ICD has also a list of 100 causes (the "P" list) for tabulation of perinatal morbidity and mortality (32).

Prevention of perinatal mortality

See page 571 under Preventive & Social Measures.

NEONATAL MORTALITY RATE

Neonatal deaths are deaths occurring during the neonatal period, commencing at birth and ending 28 completed days after birth. Neonatal mortality rate is the number of neonatal deaths in a given year per 1000 live births in that year.

The neonatal mortality rate is tabulated as:

\[
\text{Number of deaths of children under 28 days of age in a year} \times 1000
\]

Total live births in the same year

Causes of neonatal mortality

The main causes of neonatal death globally are as shown in Fig 13.

No woman should die giving life. Nor should any mother endure pregnancy and childbirth, only to go through the agony of having her child born dead or watching the baby die minutes after birth. Yet for countless women around the world, the struggle continues.

![Fig. 13: Global distribution of neonatal deaths by cause, 2013](source: 82)
world this scenario remains a tragic reality. The first 28 days of life – the neonatal period, is the most vulnerable time for a child’s survival. In order to continue to accelerate progress in under-five mortality, focussing on newborns is critical.

Neonatal mortality is a measure of intensity with which "endogenous factors" (e.g., low birth weight, birth injuries) affect infant life. The neonatal mortality is directly related to the birth weight and gestational age. Intrapartum related complications, low birth weight and preterm birth is a causal factor in 60 per cent of neonate deaths.

Prematurity and congenital anomalies account for about 60 per cent of newborn deaths, and these occur often in the first week of life. A further quarter of neonatal deaths are attributable to asphyxia – also mainly in the first week of life. In the late neonatal period, that is, after the first week, deaths attributable to asphyxia (including asphyxia and tetanus) predominates. The importance of tetanus as a cause of neonatal death, however, has diminished sharply due to immunisation.

Neonatal mortality rates of babies born to mothers with no education are nearly twice as high as those of babies born to mothers with secondary education or higher. The family’s wealth and rural/urban residence also remain powerful determinant of inequalities in neonatal mortality.

Ending child marriage, reducing adolescent pregnancy and extending birth intervals are crucial to reducing the risk of newborn mortality. Direct causes of newborn death vary from region to region. In general, the proportions of deaths attributed to prematurity and congenital disorders increase as the neonatal mortality rate decreases, while the proportions caused by infections, asphyxia, diarrhoea and tetanus decline as care improves. Patterns of low birth weight vary considerably between countries. Babies with a low birth weight are especially vulnerable to the hazards of the first hours and days of life, particularly if they are premature.

Majority of low-birth-weight babies are not actually premature but have suffered from intrauterine growth restriction, usually because of the mother’s poor health. These babies too are at increased risk of death.

The main causes of neonatal mortality are intrinsically linked to the health of the mother and the care she receives before, during and immediately after giving birth. Asphyxia and birth injuries usually result from poorly managed labour and delivery, and lack of access to obstetric services. Many neonatal infections, such as tetanus and congenital syphilis, can be prevented by care during pregnancy and childbirth. Inadequate caloric or micronutrient intake also results in poorer pregnancy outcomes. It has been argued that nearly three quarters of all neonatal deaths could be prevented if women were adequately nourished and received appropriate care during pregnancy, childbirth and in the postnatal period.

However, neonatal mortality is the most difficult part of infant mortality to alter, because of the endogenous factors which are not sensitive to improvements in environmental conditions. Neonatal mortality is greater in boys throughout the world, because newborn boys are biologically more fragile than girls.

Incidence

Each year, about 2.8 million newborns die before they are 4 weeks old and half of them die in their first 24 hours. 98 per cent of these deaths occur in developing countries.

Newborn deaths now contribute to about 44 per cent of all deaths in children under five years of age globally, and more than half of infant mortality. About 1 million babies die every year on the day of their birth and close to 2 million die in the first week of their life. Rates are highest in sub-Saharan Africa and Asia. Two-thirds of newborn deaths occur in WHO Region of Africa (31 per cent) and South East Asia (30 per cent). The gap between rich and poor countries is widening – neonatal mortality is now 6.5 times lower in high income countries than in other countries. The lifetime risk for a woman to lose a newborn baby is now 1 in 5 in Africa, compared to 1 in 125 in more developed countries (82).

India

In India the SRS estimates for the year 2012 is about 23 per 1000 live births in early-neonatal period (0–7 days), with about 25 per rural areas and 12 per urban areas. Table 19 shows the early neonatal mortality rate and percentage share of early neonatal mortality to infant deaths in the country and the major states. Among the bigger states, Kerala (4) and Madhya Pradesh and Odisha (29) are the two extremes. The percentage of early neonatal deaths to the total infant deaths during the year 2012, at the national level, has been 33.3, and it is varied from 55 in rural areas to 42.9 in urban areas. In most of the states rural proportion is relatively higher than the urban proportion. Among the bigger states, the percentage for total varied from 38.0 in Kerala to 62.5 in Karnataka.

Table 20 shows the neonatal mortality rate in the country and the percentage of neonatal deaths to infant deaths for the year 2012, both at the national and state levels. At the national level, the neonatal mortality rate was 29 and ranged from 16 in urban areas to 33 in rural areas. Among the bigger states neonatal mortality ranges from 39 each in Madhya Pradesh and Odisha to 7 in Kerala. The percentage of neonatal deaths to total infant deaths was 68.5 per cent at the national level and varied from 56.8 per cent in urban areas to 70.4 per cent in rural areas. Among the bigger states Jamnagar & Kutch (77.2) registered the highest percentage of neonatal deaths to infant deaths, and the lowest was in Assam (52.1).

CAUSES OF NEONATAL DEATHS IN INDIA

The major causes of neonatal deaths are shown in Fig. 14. It is estimated that 40 per cent of all stillbirths and neonatal deaths take place during labour and the day of birth, and about 75 per cent of total neonatal deaths occur within the first week of life. Notably half of all the maternal deaths also take place in this period (61).

India accounts for 40 per cent of the global burden of low birth weight babies with 7.5 million babies (or about 30 per cent of the country’s total annual live births) being born with a birth weight less than 2500 grams. Of these 7.5 million babies, about 60 per cent are born at term after foetal

Interventions for the reduction of neonatal mortality

Measures to reduce neonatal mortality rates and to improve newborn health are enumerated in Table 21.

**POST-NEONATAL MORTALITY RATE**

Deaths occurring from 28 days of life to under one year are called “post-neonatal deaths”. The post-neonatal death rate is defined as: “the ratio of post-neonatal deaths in a given year to the total number of live births in the same year, usually expressed as a rate per 1000” (84).

The post-neonatal mortality rate is tabulated as:

| Number of deaths of children between 28 days and one year of age in a given year |
| Total live births in the same year |
|---------------------------------|-----------------|

Whereas neonatal mortality is dominated by endogenous factors, post-neonatal mortality is dominated by exogenous (e.g., environmental and social) factors. Diarrhoea and respiratory infections are the main causes of death during the post-neonatal period. Malnutrition is an additional factor, reinforcing the adverse effects of the infections. In the developed countries, the main cause of post-neonatal mortality is congenital anomalies. Studies show that post-neonatal mortality increases steadily with birth order, and that infants born into already large families run a higher risk of death from infectious diseases.

In some areas of South East Asia (including India), during the post-neonatal period girls die more frequently than boys. This is attributed to neglect of the female children in terms of nutrition and health care (85).
### TABLE 21

**Priority areas to improve newborn health**

**Before and during pregnancy**
- Delayed child-bearing
- Well-timed, well-spaced and wanted pregnancies
- Well-nourished and healthy mother
- Pregnancy free of drug abuse, tobacco and alcohol
- Tetanus and rubella immunization
- Prevention of mother-to-child transmission of HIV
- Female education

**During pregnancy**
- Early contact with health systems including:
  - Birth and emergency preparedness
  - Early detection and treatment of maternal complications
  - Monitoring of foetal well-being and timely interventions for foetal complications
  - Tetanus immunization
  - Prevention and treatment of anaemia
  - Prevention and treatment of infections (malaria, hordvorm, syphilis and other STIs)
  - Voluntary HIV counselling and testing, and prevention of mother-to-child transmission of HIV
  - (Good diet)
  - Prevention of violence against women

**During and soon after delivery**
- Safe and clean delivery by skilled attendant
- Early detection and prompt management of delivery and foetal complications
- Emergency obstetric care for maternal and foetal conditions
- Newborn resuscitation
- Newborn care ensuring warmth and cleanliness
- Newborn cord, eye and skin care
- Early initiation of exclusive breast-feeding
- Early detection and treatment of complications of the newborn
- Special care for infants born too early or too small and/or complications
- Prevention and control of infections
- Prevention of mother-to-child transmission of HIV
- Information and counselling on home care, danger signs and care seeking
- Early post-natal contact
- Protection, promotion and support of exclusive breast feeding
- Prompt detection and management of disease in newborn infant
- Immunization
- Protection of girl child

The SRS estimates for post-neonatal mortality rate in India for the year 2012 is about 13 per 1000 live births for the whole country, and 14 for rural areas and 12 for the urban areas. The state-wise break-up is shown in Table 22.

### INFANT MORTALITY RATE

Infant mortality rate (IMR) is defined as "the ratio of infant deaths registered in a given year to the total number of live births registered in the same year; usually expressed as a rate per 1000 live births" (86). It is given by the formula:

\[
\text{IMR} = \frac{\text{Number of deaths in children less than 1 year of age in a year}}{\text{Number of live births in the same year}} \times 1000
\]

IMR is universally regarded not only as a most important indicator of the health status of a community but also of the level of living of people in general, and effectiveness of MCH services in particular. Infant mortality is given a separate treatment by demographers because: (a) infant mortality is the largest single age-category of mortality; (b) deaths at this age are due to a peculiar set of diseases and conditions to which the adult population is less exposed or less vulnerable; (c) infant mortality is affected rather quickly and directly by specific health programmes and hence may change more rapidly than the general death rate.

**International comparisons**

During the past decades, there has been a steady decline in infant mortality (Table 23)

Source: [82]

There are wide variations between countries or regions in the levels of infant mortality. The world average of IMR for 2013 has been estimated at about 34 per 1000 live births. However, IMR varies from 5 per 1000 live births in the developed countries to 61 per 1000 live births in the sub-Saharan countries. The average in the six Asian countries was 43 per 1000 live births. Although infant mortality declined significantly, the drop was greatest for the developed countries and least for least developed countries. The developed world had a much greater reduction in infant mortality compared to child mortality, while in the developed world the situation was reverse.[82]

The IMRs in industrialized countries were around 200 or even more some 150 years ago. Even at the beginning of the 20th century, USA, UK, Japan, France, etc. had rates above 140 per 1000 live births. Within 50 years (1950) a spectacular fall in the rate was observed in all developed countries. By 1980s, most developed countries achieved IMR rates below 10 per 1000 live births. Demographers opine that in most developed countries, further decline in IMRs would be difficult to achieve without some revolutionary advances in perinatology. Any further reduction in infant mortality in developed countries will depend upon preventing one of its principal causes, namely, congenital anomalies.

In general, the infant mortality rates reflect the socioeconomic development of a country. Deaths during the first four weeks are largely preventable by good health care. Most of the variations between the developed and developing world in death among newborn can be explained by differences in maternal care — about half of all pregnant women in the least developed countries have no antenatal care, and 7 out of 10 babies are born without the help of a trained birth attendant. The other major factors being malnutrition and high parity of the mother, low birth weight of the baby, and congenital anomalies.

The decline in infant mortality has been attributed to:
(a) Improved obstetric and perinatal care, e.g., availability of oxygen, foetal monitoring during labour, improved techniques for the induction of labour (b) improvement in the quality of life, that is, economic and social progress (c) better control of communicable diseases, e.g., immunization and oral rehydration (d) advances in chemotherapy, antibiotics and insecticides (e) better nutrition, e.g., emphasis on breast feeding, and (f) family planning, e.g., birth spacing.

In the industrial world, the dominant factor in the decline of infant mortality was economic and social progress (i.e., quality of life), with medical services playing secondary role. On the other hand, in most of the developing countries, this pattern has been almost turned upside down. That is, medical services (e.g., mass control of disease, immunization, antibiotics and insecticides) have made the major impact, with social and economic progress taking the supporting role. Therefore, infant mortality rates are reluctant to fall below 100 per 1000 live births in many developing countries. It is now conjectured that only socio-economic development can reaccelerate the progress and lead to further significant fall in infant deaths.

Infant mortality in India

India is still among high infant mortality rate countries (41 in the year 2012). IMR has declined slowly from 264 during 1911–15, to 129 per 1000 live births in 1970 and remained static at around 127 for many years, and then declined a bit once again to 114 in 1980 and coming down to 41 in the year 2012. Despite this significant decline, the rates are very high as compared to developed countries (Table 23) which are now mostly in the range of 3–7 per 1000 live births.

India is a vast country with widely differing populations. The all-India rate masks variations that exist among sub-groups of the population. An examination of state-wise IMR shows a vast regional variation, with Madhya Pradesh having IMR of 56 and Kerala as low as 12 per thousand live births during the year 2012. Among the larger States Kerala, Maharashtra, Punjab, Tamil Nadu, West Bengal, Andhra Pradesh, Haryana, Karnataka, Gujarat, Himachal Pradesh, and Jharkhand have achieved IMR below the national average of 47. Within each state there is rural urban variation. A critical infant mortality belt runs through Odisha, Madhya Pradesh, Assam, Uttar Pradesh, and Rajasthan; all these states have infant mortality rates above the national average.

Table 24 shows infant mortality rate in major states of India.

There is plenty of evidence to show that better control of infant mortality is related to a wider spread of literacy (particularly female literacy) and primary health care. Also, the states with the highest infant mortality are also the states with the highest fertility. Table 25 illustrates the impact of the above variables on infant mortality.

Source: (78, 87)

Table 25 shows that Kerala has managed to surpass all the Indian states in certain important measures of social development. It has the lowest infant mortality rate, the lowest birth rate and the highest literacy rate.

### Mortality pattern

**Age:** Deaths in the age-group 0–1 year account for 13.0 per cent of the total deaths in the country. About 68.5 per cent of infant deaths occur within the first month (neonatal period) of life. Of these, 51.6 per cent may die during the first week of birth (78). The risk of death is the greatest during the first 24–48 hours after birth. The problem is more acute in rural areas where expert obstetric care is scarce. (2) **Sex:** Whereas in all developed countries, male death rates are higher than female deaths, in India, after the age of one month (post-neonatal period) female deaths are invariably higher than male deaths. Social scientists have attributed this phenomenon to social factors unfavourable to females in India (88).

### Medical causes of infant mortality

The causes of infant mortality are multifactorial. The medical causes are shown in Table 26 under two subdivisions – neonatal and post-neonatal mortality.

### TABLE 26

</tbody>
</table>

The principal causes of infant mortality in India are low birth weight (57%), respiratory infections (17%), diarrhoeal diseases (4%), congenital malformations (5%) and cord infection (2%), birth injury (3%) and unclassified (18%) (69). Neonatal deaths make a major contribution to infant mortality. Whereas in developing countries, the high infant mortality is mainly due to low birth weight, and the combined effects of infection (e.g., diarrhoea, respiratory infections) and malnutrition, in developed countries, it is mainly due to congenital anomalies, anoxia and hypoxia.

### Factors affecting infant mortality

Infant mortality is due to the interaction of several factors in combination. They may be classified as biological, economic and social factors.

1. **BIOLOGICAL FACTORS**
   
   **(a) Birth weight**
   Birth weight is a major determinant of infant and perinatal mortality and morbidity. Babies of low birth weight (under 2.5 kg) and high birth weight (over 4 kg) are at special risk. Virtually, all infants weighing less than 2500 g at birth die during their first year. One major cause of low birth weight is poor maternal nutrition – not only during pregnancy, but even before that. It has been observed that the mother who was adequately nourished during her own growing-up years has an excellent chance of delivering a normal size baby even if she has taken an inadequate diet during her pregnancy. An increase in birth weight would lower the perinatal and neonatal mortality.

   **(b) Age of the mother**
   There is a definite relationship between the age of the mother and the fate of the child. Infant mortality rates are greater when the mother is either very young (below the age of 15 years) or relatively older (over 30 years). Very young mothers also tend to be poorer and less educated (89).

2. **Birth order**

   The live births are classified according to their order of rank. The highest mortality is found among first born, and the lowest among those born second. The risk of infant mortality escalates after the third birth. The fate of the 5th and later children is always worse than the fate of the 3rd child. Infant mortality from nutritional deficiencies are 3–4 times higher for infants born with fifth or higher birth order compared to the first three. These deaths occur mostly in post-neonatal period.
(d) Birth spacing
Repeated pregnancies exert a great influence on infant mortality. They cause malnutrition and anaemia in the mother, again pregnancy and low birth weight are most likely to be followed by increased risk of death in higher infant death. The mother who becomes pregnant too early and whose young child is displaced from the breast, and prematurely weaned — that baby is more prone to develop (a) protein energy malnutrition (b) diarrhoea and dehydration, both of which cause an increased mortality in infants and young children. The Khanna Study in India showed that IMR was highest for infants born after an interval of 2–3 years, lower for those born after an interval of 4 years (90). A WHO study in rural India also showed similar findings (91). Evidence from the World Fertility Survey — the largest survey into human behaviour ever undertaken — suggests that the risks to life for babies born within a year of each other is 2–4 times higher than for babies born more than 2 years apart. Wider spacing of births curtails infant mortality, and is considered as an important part of health care as immunisation (92).

(e) Multiple births
Infants born in multiple births face a greater risk of death than those in single births due to large part to the greater frequency of low birth weight among the former.

(f) Family size
Studies show the infant mortality increases with family size. The number of episodes of infectious diarrhoea, prevalence of malnutrition, and severe respiratory infections have been found to increase with family size. Besides the frequency of disease, the duration of illness is also affected by the family size. It was found that the duration of illness is much longer in families with 3 or more children. Deprivation of maternal care is also found in large families. Fewer children would mean better material care, a better share of family resources, less morbidity and greatly decreased infant mortality.

(g) High fertility
Fertility is one of the most important factors that influence infant mortality. High fertility and high infant mortality go together.

(2) ECONOMIC FACTORS
One of the most important variables affecting infant mortality rates, both directly and indirectly, is socio-economic status. The availability and quality of health care and the nature of the child’s environment are closely related to socio-economic status. Statistics reveal that infant mortality rates are highest in the slums and lowest in the richer residential localities. Major improvements in health status and a decrease in infant mortality require continuing socio-economic development, including provision of health services.

(3) CULTURAL AND SOCIAL FACTORS
(a) Breast-feeding
Infant health is related to breast feeding because of the nutritional content and natural immunizing agents contained in breast milk, at least for fully breast-fed infants. Early weaning and bottle-fed infants living under poor hygienic conditions are more prone to die than the breast-fed infants living under similar conditions.

(b) Religion and caste
The differences are attributed to socio-cultural patterns of living, involving age-old habits, customs, traditions affecting health care, clothing, child care and almost every detail of daily living.

(c) Early marriages
The baby of a teenage mother has the highest risk for newborn and post-neonatal mortality.

(d) Sex of the child
In most parts of India, female infants receive far less attention than males. This is especially the case, where there are already several female children. In many families, the birth of a female child is unwelcome. Statistics show that female infant mortality is higher than the male infant mortality. But when the total infant mortality is split into neonatal and postneonatal deaths, the picture gets reversed, i.e., neonatal death rate is higher for males than for females; post-neonatal death rate is higher for female infants than male infants (93).

(e) Quality of mothering
The art of child care has to be learnt. Even in conditions of extreme poverty, children could reasonably survive if they had an efficient mother. It is the “quality of mothering” that helps to reduce infant mortality.

(f) Maternal education
Literacy is the greatest barrier to any improvement in the health conditions. Mother’s education level, even within the same socio-economic class is a key determinant of their children’s health. There is extensive evidence (e.g. Kerala experience) that maternal education plays a major role in the decline of infant and child mortality, presumably reflecting personal health behaviour, care and access to and use of health services. Women with schooling tend to marry later, delay child-bearing and are more likely to practice family planning. They generally have fewer children with wider spacing between births.

(g) Quality of health care
Another likely factor affecting infant mortality in contemporary India is inadequate prenatal care and infrequent attendance at delivery. The percentage of deliveries attended by untrained person is very high in rural India. Shortage of trained personnel like doctors, midwives and health visitors is another determinant of high infant mortality in India. According to estimates only 47 per cent of the deliveries are attended by trained birth attendants.

(h) Broken families
Infant mortality tends to be high where the mother or father has died or separated.

(i) Illegitimacy
Illegitimacy is also an important factor contributing to high infant mortality rate. A child born out of wedlock is generally unwanted both by the mother as well as society. Consequently such a child does not receive the care in terms of nutrition and medical care that it needs.
4. Growth monitoring

It is a low cost technology available for reducing infant mortality. All infants should be weighed periodically (at least once a month) and their growth charts maintained. These charts help to identify children at risk of malnutrition early. Babies who do not thrive or show growth failure are given special health care to pull them on to the road to health. Thus systematic use of growth chart will help to promote health is children.

5. Family planning

Family limitation and spacing of births contribute substantially to lowering of infant mortality rate. The risk of death is greatly enhanced if the last child was born less than 2 years ago, and if the mother already has four or more children. Smaller sibship and longer spacing between pregnancies are associated in all societies with improved infant and child survival.

6. Sanitation

For infants and young children, the risk of dying is very closely related to the environment in which they live. Exposure to infections through contaminated food and polluted water, lack of elementary hygiene, flies and poor housing pose hazards which the young cannot escape. This is why infant mortality rate is universally recognized not only as a most important indicator of the health status of the children, but also of the level of social environment.

7. Provision of primary health care

(a) All those involved in maternity care, from the obstetrician down to the local dai should collaborate and work together as a team, (b) Prenatal care must be improved with a view to detecting mothers with “high-risk factors”, and those with prenatal conditions associated with high-risk (e.g., toxemia of pregnancy, antepartum hemorrhage, diabetes mellitus) are hospitalized and treated. (c) “Special care baby units” must be provided for all babies weighing less than 2000 g. (d) Proper referral services.

8. Socio-economic development

Since the causes of infant and perinatal mortality are also social, there is no getting away from the fact that the ultimate solution for lowering IMR and PMR lies in socio-economic development. This must include spread of education (especially female literacy), improvement of nutritional standards, provision of safe water and basic sanitation, improvement of housing conditions, the growth of agriculture and industry and the availability of commerce and communication; in short, it implies allround health and social development of the community.

9. Education

Education of females as a driving force for better health has been extensively studied and documented. Educated women generally do not have early pregnancies, are able to space their pregnancies, have better access to information related to personal hygiene and care of their children, and make better use of health care services. Higher literacy rate

Preventive and social measures

There is no single specific health programme or a single set of action that can reduce IMR. Since the aetiology of infant and perinatal mortality is multifactorial, nothing less than a multiganged approach will reduce infant and perinatal mortality. Under ideal conditions of Social Welfare, no baby should die, except possibly the few who are born with severe handicaps such as congenital abnormalities or disorders originating in uterine life. The measures needed to achieve reduction of infant mortality comprise the following:

1. Prenatal nutrition

The risk of death begins to appear even before birth, if the mother is malnourished. Therefore, the very first need is to improve the state of maternal nutrition. There is mounting evidence that the addition of even a small amount of extra food by way of supplementation to the mother’s basic diet goes a long way in improving the birth weight of babies. In a controlled study in India, poor women were fed an additional 500 kcal and 10 g of protein during the last 4 weeks of pregnancy. Their infants’ birth weights were on an average 300 g above those infants born to the control group (93, 94). This points to the need for food supplementation programmes during pregnancy. ICDS (Integrated Child Development Services) in India is active in this field.

2. Prevention of infection

The major causes of sickness and death of children in India are infectious diseases, many of which are preventable by immunization, as for example, neonatal tetanus. A large number of cases of EPI targeted diseases are reported each year. The Universal Immunization Programme launched in 1985 aims at providing protection to all the expectant mothers and children against 6 vaccine preventable diseases, and thereby ensure greater child survival.

3. Breast-feeding

The most effective measure for lowering infant mortality is to promote breast-feeding, which is a safeguard against gastrointestinal and respiratory infections and PEM.

(i) Brutal habits and customs

Certain age-old customs and beliefs greatly influence infant mortality rate. These include depriving the baby of the first milk or colostrum, frequent purgation, branding the skin, application of cowdung to the cut end of umbilical cord, faulty feeding practices and early weaning.

(ii) The indigenous dai

The untrained midwife is greatly responsible for the high infant mortality in India. She is usually an illiterate person devoid of all knowledge of rules of hygiene. Her unhygienic delivery practice is an important cause of high infant mortality.

(i) Bad environmental sanitation

Infants are highly susceptible to bad environmental sanitation. Lack of safe water supply, poor housing conditions, bad drainage, overcrowding, and insect breeding, all increase the risk of infant mortality.

The third National Family Health Survey conducted in India during 2005–06 provides vast information on factors associated with mortality in infancy and childhood.

The third National Family Health Survey conducted in India during 2005–06 provides vast information on factors associated with mortality in infancy and childhood.

Preventive and social measures

There is no single specific health programme or a single set of action that can reduce IMR. Since the aetiology of infant and perinatal mortality is multifactorial, nothing less than a multiganged approach will reduce infant and perinatal mortality. Under ideal conditions of Social Welfare, no baby should die, except possibly the few who are born with severe handicaps such as congenital abnormalities or disorders originating in uterine life. The measures needed to achieve reduction of infant mortality comprise the following:

1. Prenatal nutrition

The risk of death begins to appear even before birth, if the mother is malnourished. Therefore, the very first need is to improve the state of maternal nutrition. There is mounting evidence that the addition of even a small amount of extra food by way of supplementation to the mother’s basic diet goes a long way in improving the birth weight of babies. In a controlled study in India, poor women were fed an additional 500 kcal and 10 g of protein during the last 4 weeks of pregnancy. Their infants’ birth weights were on an average 300 g above those infants born to the control group (93, 94). This points to the need for food supplementation programmes during pregnancy. ICDS (Integrated Child Development Services) in India is active in this field.

2. Prevention of infection

The major causes of sickness and death of children in India are infectious diseases, many of which are preventable by immunization, as for example, neonatal tetanus. A large number of cases of EPI targeted diseases are reported each year. 3. Breast-feeding

The most effective measure for lowering infant mortality is to promote breast-feeding, which is a safeguard against gastrointestinal and respiratory infections and PEM.
among women is associated with low fertility and low maternal mortality, as well as low infant mortality. A study during 1991 in the Indian State of Tamil Nadu, with a population of more than 50 million, showed that a mid-day meal programme for school children together with improvement of health care for women and their babies raised retention levels in schools, reduced child mortality, increased immunization rates and led to dramatic fall in infant deaths from 90 per 1000 live births in 1986 to 27 in 1991. This in turn seems to have reduced the fertility level to 2.5 children per women in 1991 (42), and Tamil Nadu has now achieved zero population growth.

1-4 YEAR MORTALITY RATE (Child death rate)

Child death rate is the number of deaths of children aged 1-4 years per 1000 children in the same age group in a given year. It thus excludes infant mortality. The rate is computed by the formula:

\[
\text{No. of deaths of children aged 1-4 years during a year} = \frac{\text{Total no. of deaths of children aged 1-4 years at the middle of the year}}{1000}
\]

The child death rate is a more refined indicator of the social situation in a country than infant mortality rate. It reflects the adverse environmental health hazards (e.g., malnutrition, poor hygiene, infections and accidents), including economic, educational and cultural characteristics of the family. Mortality in this age group no longer depends on perinatal hazards and other endogenous factors, which often cause loss of life during the first year of life.

In the age group 1-4 years, the second year is the period when the young child runs the highest risk of dying. In the developing countries, death in the second year of life commonly accounts for 50 per cent of all deaths between 1-4 years of age. After the second year, death rates decline progressively. The infectious diseases of childhood such as measles, whooping cough, diphtheria, diarrhoea and acute respiratory infections affect mostly this age group, and can lead to high case-fatality rate in malnourished children.

Mortality rate at ages 1-4 years is about 30 in some developing countries whereas it is less than one in developed countries. The contrast is glaring. While on an average, the IMR is 10-20 times higher in developing countries than in the developed countries, the average mortality rate between the age 1-4 years is 30-50 times higher.

In India, for the year 2012, 1-4 years age mortality was estimated to be 2.8 per cent of total deaths. Like infant mortality, 1-4 year age mortality also shows wide state-wise variations as shown in Table 27. The states reporting rates higher than the national average are Madhya Pradesh 4.6, Uttar Pradesh 4.4, Jharkhand 4.0, Bihar 5.3, and Assam with 5.2 per cent of total deaths (78). Kerala recorded the lowest with 0.2 per cent followed by Andhra Pradesh with 0.4 per cent.

The leading causes of death in 1-4 years age group in developing countries are diarrhoeal diseases and respiratory infections, closely followed by other communicable diseases such as whooping cough and measles. When combined with malnutrition these diseases have high case fatality rates. In the developed countries deaths from infectious diseases are quite rare, while accidents are the leading cause of death from the age of one year. Four groups of home accidents have been identified – (a) falls from unprotected stairs, and balconies (b) suffocation (c) burns and scalds (d) poisoning. Almost all accidents are preventable. The factors such as congenital anomalies and neoplasms are not easy to prevent or to cure. These conditions also affect children in developing countries, but their relative importance is overshadowed by infections.

UNDER-5 MORTALITY RATE (Child mortality rate)

UNICEF defines this as the "annual number of deaths of children under 5 years, expressed as a rate per 1000 live births." More specifically, it measures the probability of dying between birth and age 5 years of age. UNICEF considers this as the best single indicator of social
development and well-being rather than GNP per capita, as the former reflects income, nutrition, health care and basic education etc (90). The rate is calculated by the formula:

\[
\text{Number of deaths of children less than 5 years of age in a given year} \times 1000
\]

= Number of live births in the same year

The dramatic decline in preventable child deaths over the past quarter of a century is one of the most significant achievements in human history. Since 1990, the global under-five mortality rate has declined by nearly half (49 per cent), from 90 deaths per 1,000 live births to 46 deaths in 2013. Over the same period, the neonatal mortality rate (the probability of dying in the first 28 days after birth) has been reduced by 40 per cent, from 33 deaths per 1,000 live births to 20. The progress is especially dramatic when viewed in terms of the decline in the number of under-five deaths. In 1990, 12.7 million children under age 5 died. In 2013, by contrast, that number fell to 5.3 million, a reduction of 50 per cent. In other words, about 17,000 children under 5 died everyday in 1990 – 17,000 fewer than in 1990 (82).

The global progress in reducing newborn deaths is almost as striking. Between 1990 and 2013, the number of newborn babies who died within the first 28 days of life declined from 4.7 million to 2.8 million. The world saved almost 100 million children – among them, 24 million newborns – who would have died had mortality remained at 1990 rate. The bulk of progress has taken place since Millennium Development Goals were set in the year 2000.

Not surprisingly the burden of under-five mortality is concentrated in the world’s poorest regions and countries. The latest data from 2013 show that sub-Saharan Africa shoulders the world’s highest under-five mortality rates. All 12 countries with an under-five mortality rate of 100 or more deaths per 1,000 live births are in sub-Saharan Africa, and 10 of these are in West and Central Africa. On an average, 1 out of every 11 children born in Sub-Saharan Africa dies before age 5. This is nearly 15 times the average rate (1 in 159) in high-income countries. Sub-Saharan Africa and South Asia remain the regions with the greatest numbers of child deaths. In 2013, about half of global under-five deaths occurred in sub-Saharan Africa and 32 per cent in South Asia.

Table 29 shows child mortality rate in some selected developed and developing countries.

Causes of under-five deaths

Understanding the causes of child mortality provides important public health insights. Of the 6.2 million deaths in children under 5, that occurred in 2013, almost one-third (38%) were caused by infectious diseases and conditions such as pneumonia, diarrhoea, malaria, meningitis, tetanus, HIV and measles. Around 44% of all under-five deaths occurred in the neonatal period (within the first 28 days of life), the majority from preterm birth complications and intrapartum-related complications (complications during delivery). Globally, more than half of the under-five deaths are attributable to undernutrition (82).

Worldwide, the leading causes of death among children under 5 (1-59 months) include pneumonia (13% of all under-five deaths), preterm birth complications (13%), diarrhoea (9%), intrapartum-related complications (9%), malaria (7%), and neonatal sepsis, meningitis and tetanus (6%). Cross-country comparisons show a wide variation among countries in the proportions of under-five deaths attributable to specific causes. Such variations indicate that the optimal programmatic approaches for child survival will differ from country to country. Fig. 15 shows the causes of death of children under-five in 2013.

Summarising data across regions and countries masks

- Diarrhoea (post-natal), 9%
- Injuries, 5%
- Pneumonia (post-natal), 13%
- Malaria, 7%
- Meningitis, 2%
- All other causes of death, 16%
- AIDS, 2%
- Measles, 2%

Globally, nearly half of all deaths among children under-5 are attributable to undernutrition

FIG. 15

Global distribution of deaths among children under-5 by cause, 2013
substantial differences in the distribution of causes of death. Approximately 90% of all malaria and HIV/AIDS deaths in children, more than 50% of measles deaths and about 40% of pneumonia and diarrhoeal deaths are in the African Region. On the other hand, deaths from injuries and non-communicable diseases other than congenital anomalies, account for 20–30% of under-five deaths in the region of the Americas and in the European and Western Pacific Regions (96).

The steady improvement in under-five survival is explained by a combination of advances. They include developments in science and technology (for example, oral rehydration salts that treat diarrhoeal dehydration and insecticide-treated mosquito nets for malaria prevention), improved health-seeking behaviours (such as women’s increasing use of antenatal care and skilled providers for care around the time of birth), improved sanitation and improved coverage of effective interventions to prevent or treat the most important causes of child mortality. Each one of these advances is due to the political will of committed governments and the expansion of innovative partnerships involving civil society and the public and private sectors. Taken together, these efforts are reducing the number of young lives claimed by the leading causes of under-five mortality: pneumonia, diarrhoea, malaria, measles and AIDS. As a result 2.2 million fewer children died from these five diseases in 2013.

The Expanded Programme on Immunization started in 1974 and widened range of vaccines routinely provided, from smallpox, BCG and DPT to include polio and measles and more recently hepatitis B. It set out to increase coverage in line with the international commitment to achieve the universal childhood immunization goal of 80 per cent coverage in every country.

As mortality from diarrhoeal diseases and vaccine preventable diseases decreased, pneumonia came to the forefront as a cause of death, and in the 1980s programmes were developed around simplified diagnostic and treatment techniques. In the meantime, promotion of breast-feeding and complementary feeding for healthy growth and development, e.g., oral rehydration therapy for diarrhoea; antibiotics for sepsis, pneumonia and ear infection, antimarialts and insecticide-treated bed-nets; vitamin A, treatment of anaemia, promotion of breast-feeding and complementary feeding for healthy nutrition and for recovery from illness; and immunization. Some countries have included guidelines to treat children with HIV/AIDS, others for dengue fever, whooping or sore throat, or for the follow-up of healthy children.

More recently, Every Newborn Action Plan proposes five strategic objectives for achieving two clear and measurable targets: (1) Ending preventable newborn deaths by 2015, all countries reach a national target of 10 or fewer newborn deaths per 1000 live births and continue to reduce death and disability; and (2) Ending preventable stillbirths—by 2035, all countries reach the target of 10 or fewer stillbirths per 1000 total births and continue to narrow gaps in equity. Developed under WHO and UNICEF, the ENAP recommends the integrated delivery of high-impact interventions across the full continuum of maternal and newborn care, led by midwives during labour and newborn care during the first week of life and care of small and sick newborns. Fig. 16 shows the package of interventions.

Focus of the Every Newborn Action Plan

The time around birth results in the majority of maternal and newborn deaths and stillbirths as well as human capital loss. These packages have the highest impact yet some of the lowest coverage of equitable and quality care across the continuum.

Packages of interventions in the continuum of care
Child mortality rate in India

In India, the deaths among young children are monitored by the Registrar General’s Office. The DHS estimates of child mortality rate is calculated as the annual number of deaths in children < 5 years of age per 1000 live births. This is why, while reviewing reports and analyzing data, these differences should be kept in mind (52).

Each year 27 million children are born in India, around 10 per cent of them do not survive to 5 years of age. In absolute figures, India contributes to 25 per cent of the over 6.9 million under-five deaths occurring worldwide every year. Nearly half of the under-five deaths occur in neonatal period. The mortality rates for children below age 5 years for the year 2013, by residence are shown in Table 27. At the national level the mortality rate was estimated at 56 per 1000 live births, and the rate varies from 15 in Kerala to 83 in Assam. The rate for rural areas is about 66 and for urban areas 38. The mortality rate in female children is higher than the male children (97).

Among children who die before their fifth birthday, almost one-third die of infectious diseases nearly all of which are preventable. The estimates of the cause of death for the year 2013 are shown in Fig. 17.

Pneumonia has emerged as the leading cause of neonatal death, underlining the need for rapid scale-up of maternal health interventions in order to improve neonatal health outcomes. The interventions included in the RMNCH+A approach essentially look to address the major causes of death as well as the three delays in accessing and utilizing healthcare services. These interventions are described in the later sections of this document.

Other causes of death among children under 5 years, India, 2013

Infections 3%  
Meningitis 2%  
Malaria 1%  
Measles 3%  
Diarrhoea 10%  
Other 5%  
Prematurity 24%  
Congenital anomalies 5%  
Neonatal tetanus 1%  
Neonatal sepsis 8%  
Intrapartum-related complications, including birth asphyxia 12%  
Under-5 mortality rate

management of childhood diarrhoea during the NRHM period has been slow and of variable quality across states (98). To pursue the goals of NPP, the Government of India constituted a National Technical Committee on Child Health in June 2000. New initiatives taken on the basis of this are (68):
- Launch of Immunization Strengthening Project;
- Organization of RCH camps, health "melas" and RCH outreach schemes to reach disadvantageous segments of the population;
- Launch of Hepatitis B vaccine in the immunization programme;
- Operationalization of newborn care facilities in identified weak districts;
- Operations research by ICMR for provision of home-based neonatal care through community-level providers;
- Policy for exclusive breast-feeding upto 6 months of age;
- Preparation and approval of concept note on development of community-based midwives;
- Implementation of Dais training to provide key messages for newborn health in 165 districts; and
- Adaptation of IMCI to incorporate newborn issues and development of IMNCI.

The Government of India established an IMCI Adaptation Committee that has led the development of Integrated Management of Newborn and Child Health (IMNCI). Separate tools and guidelines have been produced that focus on newborn issues; these are used to train field staff and for supervision and monitoring purposes.

CHILD SURVIVAL INDEX

The basic measure of infant and child survival is the Under-5 mortality (number of deaths under the age of 5 years, per 1000 live births). A child survival rate per 1000 births can be simply calculated by subtracting the Under-5 mortality rate from 1000. Dividing this figure by ten shows the percentage of those who survive to the age of 5 years (59).

\[
\text{Child survival rate} = \frac{1000 - \text{under-5 mortality rate}}{10}
\]

The following table (Table 30) shows the child survival rates of some countries.

The difference in the survival rates of children in developed and developing countries is a grim pointer to the Third World's need for preventive services. Through breast-feeding, adequate nutrition, clean water, immunization programmes, oral rehydration therapy and birth spacing, a virtual revolution in child survival could be achieved. The impact would be dramatic in humanitarian and fertility terms.

INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI)

The notion of integration has a long history. Integration is supposed to tackle the need for complementarily of different independent services and administrative structures, so as to better achieve common goals. In 1950s, the goals were defined in terms of outcome, in 1960s of process and in the 1990s of client impact. Integration has different meanings at different levels. At the national level it means care management; at the point of delivery it means that multiple interventions are provided through one delivery channel, e.g., where vaccination is used as an opportunity to provide vitamin A to the child, boosting efficiency and coverage. At the system level integration means bringing together management and support function of different sub-programmes and ensuring complementarity between different levels of care. IMCI is now the only child health strategy that aims for improved integration at these three levels simultaneously. More than just adding more programmes to a single delivery channel, it has sought to transform the way the health system looks at the child care.

Most sick children present with signs and symptoms related to more than one conditions. This overlap means that a single diagnosis may not be possible or appropriate, and that treatment may be complicated by the need to combine therapy for several conditions. Surveys of the management of sick children at these facilities reveal that many children are not properly assessed and treated and that their parents are poorly advised. Providing quality care to sick children in these conditions is a serious challenge. In response to this challenge, WHO and UNICEF developed a strategy known as IMCI. The strategy combines improved management of childhood illness with aspects of nutrition, immunization, and other important disease prevention and health promotion elements. The objectives are to reduce deaths and the frequency and severity of illness and disability and to contribute to improved growth and development.

The strategy includes three main components:
- Improvements in the case-management skills of health staff through the provision of locally adapted guidelines on IMCI and through activities to promote their use.
- Improvements in the health system required for effective management of childhood illness.
- Improvements in family and community practices.

The core of the IMCI strategy is an integrated management of the most common childhood problems, with a focus on the most important causes of death i.e., diarrhoea, ARI, malaria, measles and malnutrition. A guided process of adaptation ensures that the guidelines, and the learning materials that go with them, reflect the epidemiology within a country and are tailored to fit the needs, resources and capacity of a country's health system.
The clinical guidelines, which are based on expert clinical opinion and research results, are designed for the management of sick children aged 1 week up to 5 years. They promote evidence-based assessment and management, using a syndromic approach that supports the rational, effective and affordable use of drugs. They include methods for assessing signs that indicate severe disease; assessing a child's nutrition, immunization, and feeding; teaching parents how to care for a child at home; counselling parents to solve feeding problems; and advising parents about when to return to a health facility. The guidelines also include recommendations for checking the parent's understanding of the advice given and for showing them how to administer the first dose of treatment.

When assessing a sick child, a combination of individual signs leads to one or more classifications, rather than to a diagnosis. IMCI classifications are action oriented and allow a health care provider to determine if a child should be urgently referred to another health facility, if the child can be treated at the first-level facility (e.g. with oral antibiotic, antimarial, ORS, etc.) or if the child can be safely managed at home.

The complete IMCI case management process involves the following elements (100):

a. Assess a child by checking first for danger signs (or possible bacterial infection in a young infant), asking questions about common conditions, examining the child, and checking nutrition and immunization status. Assessment includes checking the child for other health problems.

b. Identify a child's illnesses using a colour-coded triage system. Because many children have more than one condition, each illness is classified according to whether it requires:
   - urgent pre-referral treatment and referral (pink), or
   - specific medical treatment and advice (yellow), or
   - simple advice on home management (green).

c. After classifying all conditions, identify specific treatments for the child. If a child requires urgent referral, give essential treatment before the patient is transferred. If a child needs treatment at home, develop an integrated treatment plan for the child and give the first dose of drugs in the clinic. If a child should be immunized, give immunization.

d. Provide practical treatment instructions, including teaching the caretaker how to give oral drugs, how to feed and give fluids during illness, and how to treat local infections at home. Ask the caretaker to return for follow-up on a specific date, and teach her how to recognize signs that indicate the child should return immediately to the health facility.

e. Assess feeding, including assessment of breast-feeding practices, and counsel to solve any feeding problems found. Then counsel the mother about her own health.

f. When a child is brought back to the clinic as requested, give follow-up care and, if necessary, reassess the child for new problems.

The IMCI guidelines address most, but not all, of the major reasons a sick child is brought to a clinic. A child returning with chronic problems or less common illnesses may require special care. The guidelines do not describe the management of trauma or other acute emergencies due to accidents or injuries.

Although AIDS is not addressed specifically, the case management guidelines address the most common reasons children with HIV seek care: diarrhoea and respiratory infections. When a child, who is believed to have HIV, presents with any of these common illnesses, he or she can be treated the same way as any child presenting with an illness. If a child's illness does not respond to the standard treatments described or if a child becomes severely dehydrated, or returns to the clinic repeatedly, the child is referred to a hospital for special care.

Case management can only be effective to the extent that families bring their sick children to a trained health worker for care in a timely way. If a family waits to bring a child to a clinic until the child is extremely sick, or takes the child to an untrained provider, the child is more likely to die from the illness. Therefore, teaching families when to seek care for a sick child is an important part of the case management process.

The case management process is presented on two different sets of charts: one for children age 2 months up to five years, and one for children age 1 week up to 2 months. Annexure A at the end of this chapter shows the flowchart about the IMNCI guidelines for the management of various conditions of childhood.

The Indian version of IMCI is known as IMNNI (Integrated Management of Neonatal and Childhood Illness) as it includes the first 7 days of age in the programme. Please refer to page 59 of chapter 7 for further details.

CONGENITAL MALFORMATIONS

Definitions

Congenital disorders are defined as "those diseases that are substantially determined before or during birth and which are in principle recognizable in early life" (85). Some are obvious at birth like, cleft palate; some are obvious in early life like congenital dislocation of hip which may escape detection until walking should commence and some may not become apparent until much later in life, like patent ductus arteriosus which may close during the first year of life or even later. Internal defects, when they are not lethal, may go unrecognized. In addition to the list of late diagnoses are a host of inborn errors of metabolism like PKU, Tay-Sachs disease, galactosemia, and mental retardation. Some defects are classified as major which may require surgical intervention, and some are classified as minor that have no functional implications like skin tags in front of the ear. Thus a broad definition of congenital malformation includes not only structural defects but also molecular and cellular abnormalities present at birth (101). A WHO document in 1972, however, held that the term congenital malformation should be confined to structural defects at birth, and the term congenital anomaly being used to include all biochemical, structural and functional disorders present at birth (84). Thus the basic difficulty in the definition of congenital defects is the actual definition of the term without which comparisons between studies are difficult to make.

Incidence

Congenital anomalies (also referred to as birth defects) affect approximately 1 in 33 infants and result in approximately 3.2 million birth defect-related disabilities every year. An estimated 270,000 newborns die during the first 28 days of life every year from congenital anomalies. Congenital anomalies may result in long-term disability,
which may have significant impacts on individuals, families, health-care systems and societies. The most common serious congenital disorders are heart defect, neural tube defects and Down syndrome. Congenital anomalies may have a genetic, infectious or environmental origin; although in most of the cases it is difficult to identify their cause (102).

**Causes**

The aetiology of most congenital anomalies is poorly understood; both genetic and environmental factors have been implicated. They include:

1. **GENETIC FACTORS**: The congenital disorders with genetic aetiology are: (a) Chromosomal abnormalities: The chromosome is either missing or in excess. The examples include Down’s syndrome, Rett syndrome and Turner’s syndrome. (b) Inborn errors of metabolism: These include PKU, Tay-Sachs disease and galactosaemia. (c) Others: Other genetically inherited disorders, presumably due to single gene defects, are much more common than conditions with demonstrable chromosomal abnormalities. Single gene disorders may be dominant (e.g., Huntington’s chorea), recessive (e.g., thalassemia, sickle cell disease) or sex-linked disorders (e.g., haemophilia). (d) Those with probable or possible genetic aetiology: This applies to congenital dislocation of hip, club foot and neural tube defects.

2. **ENVIRONMENTAL FACTORS**: These include intrauterine Infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), Drugs (e.g., thalidomide, stilboestrol, anti-convulsants, tobacco: high dose of vitamin A), Infections, congenital malformations complicated by pregnancy (e.g., diabetes, cardiac failure), Irradiation, and Dietary factors (e.g., folic acid deficiency).

**Risk factors**

These factors significantly associated with the occurrence of congenital malformations are: (a) Maternal age: Advanced maternal age at conception is a recognized risk factor. The overall risk of giving birth to an infant with Down’s syndrome is 1:900. The risk rises sharply with age; it is 1:67 for those aged 40–45. (b) Consanguinity: In consanguineous marriages (e.g., first-cousin and uncle–niece marriages), there is a relatively high incidence of mental retardation and congenital malformations.

**Prenatal diagnosis**

It is now possible to detect certain congenital anomalies in utero using the following techniques: (a) **Alpha fetoprotein**: Neural tube defects can be detected by measurement of a specific protein of fetal origin, called alpha fetoprotein in maternal blood and in amniotic fluid during pregnancy. (b) **Ultrasound**: This can be used to visualize the foetus and detect many abnormalities of the foetus. (c) **Amniocentesis**: This test is possible only in the second trimester (i.e., after the completion of 12 weeks). It can detect many abnormalities (e.g., Down’s syndrome, Neural tube defects). (d) **Chorionic villi sampling**: This new technique allows prenatal diagnosis at 9 to 11 weeks of pregnancy. By this test, the chromosomal status can be easily determined. Prenatal diagnosis of congenital abnormalities offers the parents the option of therapeutic abortion.

**PREVENTION OF CONGENITAL DEFORMITIES**

There are 3 main approaches to the reduction of congenital abnormalities: (103). (1) By discouraging further reproduction after the birth of a malformed child; after such a birth, the frequency of malformations in subsequent pregnancies is increased by about 10 times; (2) The avoidance of pregnancy in circumstances where malformations are likely to occur, e.g., advanced maternal age and Down’s syndrome; (3) the identification and removal of teratogens such as certain drugs (e.g., thalidomide, steroid hormones, folate antagonists, anti-convulsants); infective agents (e.g., rubella, cytomegalovirus, herpes simplex virus, varicella zoster virus, Toxoplasma gondii); and physical agents such as X-rays and irradiation. Immunization against rubella is now routine in some countries which is bound to lead to some reduction in congenital abnormalities. A largely unapped preventive measure is the avoidance of drugs in pregnancy except where they are absolutely necessary (104).

Congenital malformations may be regarded as one form of reproductive failure. The most unfavourable environmental and genetic factors result in sterility, and the favourable factors lead to normal reproduction. Between these extremes there may be abortions, stillbirths, premature births or neonatal deaths. Malformation represent a relative reproductive "success" when compared with sterility or early abortion (105). Penrose (1961) stressed that major advances in the prevention of malformations must be achieved by attention to environmental factors rather than by attempting to improve heredity. It is more within reach than genetic control (106).

**SCHOOL HEALTH SERVICE**

School health is an important branch of community health. According to modern concepts, school health service is an essential and powerful means of raising community health, and more important, in future generations. The school health service is a personal health service. It has developed during the past 70 years from the narrower concept of medical examination of children to the present-day broader concept of comprehensive care of the health and well-being of children throughout the school years.

**Historical development**

The beginning of School Health Service in India dates back to 1909, when for the first time medical examination of school children was carried out in Baroda city. The Bhor Committee (1946) (107) reported that School Health Services were practically non-existent in India, and where they existed, they were in an under-developed state. In 1953, the Secondary Education Committee emphasized the need for medical examination of pupils and school feeding programmes. In 1960, the Government of India constituted a School Health Committee to assess the standards of health and nutrition of school children and suggest ways and means to improve them. The Committee submitted its report in 1961, which contains many useful recommendations (108). During the Five Year Plans, many State Governments have provided for school health, and school feeding programmes. Inspite of these efforts to improve school health, it must be stated that in India, as in other developing countries, the school health services provided are hardly more than a token service because of shortage of resources and insufficient facilities.

**HEALTH PROBLEMS OF THE SCHOOL CHILD**

Any discussion of a school health service must be based
on the local health problems of the school child, the culture of the community and the available resources in terms of money, material and manpower. While the health problems of school children vary from one place to another, surveys carried out in India indicate that the main emphasis will fall in the following categories: (1) malnutrition (2) infectious diseases (3) intestinal parasites (4) diseases of skin, eye and ear, and (5) dental caries.

OBJECTIVES OF SCHOOL HEALTH SERVICE
The objectives of the programme of a school health service are as follows (109, 110):
1. the promotion of positive health
2. the prevention of diseases
3. easy diagnosis, treatment and follow-up of defects
4. awakening health consciousness in children
5. the provision of healthful environment.

Aspects of School Health Service
The tasks of a school health service are manifold, and vary according to local priorities. Where resources are plentiful, special school health services may be developed. Some aspects of a school health service are as follows:
1. Health appraisal of school children and school personnel
2. Remedial measures and follow-up
3. Prevention of communicable diseases
4. Healthful school environment
5. Nutritional services
6. First-aid and emergency care
7. Mental health
8. Dental health
9. Eye health
10. Health education
11. Education of handicapped children
12. Proper maintenance and use of school health records.

1. Health appraisal
The health appraisal should cover not only the students but also the teachers and other school personnel. Health appraisal consists of periodic medical examinations and observation of children by the class teacher. (a) Periodic Medical Examination: The school health committee (1961) in India recommended medical examination of children at the time of entry and thereafter every 4 years (108). In big cities, where facilities for medical examination are available, this could be more frequent. The initial examination should be thorough and unhampered and should include a careful history and physical examination of the child, with tests for vision, hearing and speech. A routine examination of blood and urine should be carried out. Clinical examination for nutritional deficiency, and examination of faeces for intestinal parasites are particularly important in India. Tuberculin testing or mass screening should not be withheld. The parents should be persuaded to be present at these examinations. The teacher should help in the medical inspection by recording the medical history, regular (quarterly) recording of height and weight, annual testing of vision, and preparing children for the medical examination by helping them understand the "how" and "why" of health appraisal.
(b) School Personnel: Medical examination should be given to teachers and other school personnel as they form part of the environment to which the child is exposed. (c) Daily Morning Inspection: The teachers is in a unique position to carry out the "daily inspection", as he is familiar with the children and can detect changes in the child's appearance or behaviour that suggest illness or improper growth and development. The following cues will help the school teacher in suspecting children who need medical attention: (1) unusually flushed face (2) any rash or spots (3) symptoms of acute cold (4) coughing and sneezing (5) sore throat (6) rigid neck (7) nausea and vomiting (8) red or watery eyes (9) headache (10) chills or fever (11) listlessness or sleepiness (12) disinclination to play (13) diarrhoea (14) pains in the body (15) skin conditions like scabies and ringworm (16) pediculosis (111). Children showing any such signs or symptoms should be referred to the school medical officer. Teacher observation of school children is of particular importance in India because of the limited number of medical personnel for school health work. For this work, the teachers should be adequately trained during Teacher Training Courses and subsequently by short In-service Training Courses.
2. Remedial measures and follow-up
Medical examinations are not an end in themselves; they should be followed by appropriate treatment and follow-up. Special clinics should be conducted exclusively for school children at the primary health centres in the rural areas, and in one of the selected schools or dispensaries for a group of about 5,000 children in the urban areas (110). The clinic days and time should be announced to all the concerned schools. Considering the high prevalence of dental, eye, ear, nose and throat defects in the school children in India, special clinics should be secured or provided for the exclusive use of school children for examination and treatment of such defects. In the big cities, the required number of specialists should be employed in the School Health Service. There should be provision for beds in the existing referral hospitals for the children to be admitted for investigation and treatment as and when required.
3. Prevention of communicable diseases
Communicable diseases control through immunisation is the most emphasised school health service function. A well-planned immunisation programme should be drawn up against the common communicable diseases.
A record of all immunisations should be maintained as part of the school health records. When the child leaves school, the health record should accompany him.
4. Healthful school environment
The school building, site and equipment are part of the environment in which the child grows and develops. A healthful school environment therefore is necessary for the best emotional, social and personal health of the pupils.
Schoo schools should also serve as demonstration centres of good sanitation to the community. The following minimum standards for sanitation of the school and its environs have been suggested in India (109, 110, 112):
(1) Location: The school should normally be centrally situated with proper approach roads and at a fair distance from busy places and roads, cinema houses, factories, railway tracks and market places. The school premises should be properly fenced and kept free from all hazards.
(2) Site: The site should be on suitable high land, and not subject to inundation or damness and can be properly drained. The School Health Committee (1951) had recommended that 10 acres of land be provided for higher elementary schools and 5 acres for primary schools with an additional one acre of land per 100 students. In congested area, the nearest public park or playground should be made available to the students. (3) Structure: Nursery and secondary schools, as far as possible, be single storied. Exterior walls should have a minimum thickness of 10 inches and should be heat resistant. (4) Classroom: Verandhas should be attached to classrooms. No classroom should accommodate more than 40 students. Per capita space for students in a classroom should not be less than 10 sq. ft. (5) Furniture: Furniture should suit the age group of students. It is desirable to provide single desks and chairs. Desks should be of ‘minus’ type. Chairs should be provided with proper back-rests, with facilities for desk-work. (6) Doors and windows: The windows should be broad with the bottom sill, at a height of 2’-6” from the floor level; combined door and window area should be at least 25 per cent of the floor space; windows should be placed on different walls for cross-ventilation; the ventilators should not be less than 2 per cent of the floor area. (7) Colour: Inside colour of the classroom should be white and should be periodically white-washed. (8) Lighting: Classrooms should have sufficient natural light, preferably from the left, and should not be from the front. (9) Water supply: There should be an independent source of safe and potable water supply, which should be continuous, and distributed from the taps. (10) Eating facilities: Vendors other than those approved by the school authorities should not be allowed inside school premises; there should be a separate room provided for mid-day meals. (11) Laboratory: Privies and urinals should be provided for at least 40 students and one latrine for 100 students. Arrangements should be separately made for boys and girls.

5. Nutritional services

A child who is physically weak will be mentally weak, and cannot be expected to take full advantage of schooling. The diet of the school child should, therefore receive first attention. The diet should contain all the nutrients in proper proportion, adequate for the maintenance of optimum health. Studies in India have shown that nutritional disorders are widely prevalent among school children, particularly deficiencies relating to proteins; vitamins A, C, thiamine and riboflavin, calcium and iron.

Mid-day School Meal: In order to combat malnutrition and improve the health of school children, it is now an accepted procedure in all advanced countries to provide a good nourishing meal to school children. The School Health Committee (1951) recommended that school children should be assured of at least one nourishing meal (113). Those who can afford it may bring their lunch packets from home, and during lunch hours take their meals in school. Otherwise, schools should have some arrangement for providing mid-day meals through their own canteens on a ‘no profit no loss’ basis. In view of the limited finances in India, it is recommended that the school meal should provide at least one-third of the daily calorie requirement and about half of daily protein requirement of the child.

Applied Nutrition Programme: UNICEF is assisting in the implementation of the Applied Nutrition Programme in the form of implements, seeds, manure and water supply equipment. Wherever land is available, the facilities provided by the UNICEF should be utilized in developing school gardens. The produce may be utilized in the school feeding programme as well as for nutritional education. Specific Nutrients: Advances in the knowledge of nutrition have revealed that specific nutrients may be necessary for the prevention of some vitamin disorders. Dental caries, endemic goitre, rickets, blindness, protein malnutrition, anemia and a host of other nutrient disorders are entirely preventable. The intake of specific nutrients is indicated where such nutrient disorders are problems in a community.

6. First-aid and emergency care

The responsibility of giving first-aid and emergency care to pupils who become sick or injured on school premises rests with the teacher and therefore all teachers should receive adequate training during “Teacher Training Programmes” or “In-service Training programmes” to prepare them to carry out this obligation. The emergencies commonly met within schools are (a) accidents leading to minor or serious injuries, and (b) medical emergencies such as gastroenteritis, colic, epileptic fits, fainting, etc. In every school a fully equipped First-aid Post should be provided as per regulations of St. John Ambulance Association of India.

7. Mental health

The mental health of the child affects his physical health and the learning process. Juvenile delinquency, maladjustment, and drug addiction are becoming problems among school children. The school is the most strategic place for shaping the child’s behaviour and promoting mental health. The school teacher has both a positive and preventive role—he should be concerned with helping all children develop into mature, responsible and well adjusted adults. The adult routine should be so planned that there is enough relaxation between periods of intense work, and every effort should be made to relieve the tedium of the class room. No distinction should be made between race, religion, caste or community; between the rich and poor; and between the clever and the dull. It is now increasingly realized that there is a great need for vocational counsellors and psychologists in schools for guiding the children into careers for which they are suited.

8. Dental health

Children frequently suffer from dental diseases and defects. Dental caries and periodontal disease are the two common dental diseases in India. A school health programme should have facilities for dental examination, at least once a year. In the developed countries, dental hygienists are employed in schools to assist the school dentist with the examination of the teeth. They make preliminary inspection of the teeth and do prophylactic cleansing which is of great value in preventing gum troubles and in improving personal appearance. They take part in the teaching of dental hygiene as they work with the children.

9. Eye health services

Schools should be responsible for the early detection of refractive errors, treatment of squint and amblyopia, and care and treatment of eye infections such as trachoma. Administration of vitamin A to children at risk, has shown gratifying results. In other words, basic eye health services should be provided in schools.
10. Health education

The most important element of the school health programme is health education. The goal of health education should be to bring about desirable changes in health knowledge, in attitudes and in practice, and not merely to teach the children a set of rules of hygiene.

Health education in schools should cover the following areas: (1) Personal hygiene: Health education programme in schools should be lively, practical and based on everyday needs and interests of children. The need for hygiene of skin, hair, teeth and clothing should be impressed upon them. Attention to posture is also important. Children often adopt bad postures while sitting and standing. Such tendencies, should be observed and corrected. It is increasingly recognized that many degenerative diseases of adults have their origin in poor health habits formed early in life. Cigarette smoking is an example of a public health problem that should be tackled in schools.

(2) Environmental Health: Encouraging young people to take part in health activities and keep their environment clean is an important function of school health services. Visits to observe community health programmes, and even better participation in community action programmes (e.g., vaccination, fly control campaigns, conservation of sanitary wells and latrines) are excellent opportunities for health education. (3) Family life: Family life education is being increasingly recognized as a priority in both developed and developing countries. The school health service is concerned not only with the development of healthy lives but also with healthy attitudes towards human reproduction.

Health education in schools is a function of the school teacher. The health officer and the public health nurse/health worker/health assistant may furnish teaching materials and advice, but the teacher is the key person in the presentation of the material to the children. To do this important work, the teacher should be well versed in health education techniques, and sincerely interested in the welfare of the pupils. Children take back to their parents the health instructions they receive in schools, and even more important, when they become adults they apply this knowledge to their own families. In developing countries, where ill-health is a major problem, "every school child is a health worker".

11. Education of handicapped children

The ultimate goal is to assist the handicapped child and his family so that the child will be able to reach his maximum potential, to lead as normal a life as possible, to become as independent as possible, and to become a productive and self-supporting member of society. The resources for managing handicapped child vary from country to country. It requires the cooperation of health, welfare, social and educational agencies.

12. School health records

A cumulative health record of each student should be maintained. Such records should contain (a) Identifying data—name, date of birth, parent's name and address, etc. (b) past health history (c) record of findings of physical examination and screening tests and record of services provided. The purpose of maintaining school health records is to have cumulative information on the health aspects of school children in order to give continuing intelligent health supervision. These records will also be useful in analysing and evaluating school health programmes and providing a useful link between the home, school and the community.

School health administration

The health of the school child is the responsibility of the parents, teachers, health administrators and the community. To achieve this, the function of the school health service depends largely on effective coordination between the participating agencies. There is no uniform pattern of school health administration, but broad and similar. In England, school health service is part of the Education service of the country. In India, school health service is administered by different departments in different States—these are usually the departments of Health and Education. The School Health Committee set up by the Government of India in 1960 recommended that school health service should be an integral part of the general health services. The general health services in India are administered largely through the primary health centres in the rural areas, where the bulk of India's population lives. School health service is therefore an important function of the primary health centres.

(a) Primary health centres

The primary health centres are charged with the responsibility of administering school health service within their jurisdiction. It requires a whole-time, medical officer to cover 5,000 to 6,000 children a year. The School Health Committee (1961) has therefore recommended that the staff of the primary health centres should be augmented by additional staff to carry out effectively the school health programme.

(b) School Health Committees

The School Health Committee (1961) in India recommended the formation of school health committees at the village, block, district and state level and national level. These Committees should mobilize community resources and make the school health programme continuous and self-sustaining. The National School Health Council will be an advisory and coordinating body.

HANDICAPPED CHILDREN

Definitions

"Handicap" may be defined as "reduction in a person's capacity to fulfill a social role as a consequence of an impairment, inadequate training for the role, or other circumstances. Applied to children, the term usually refers to the presence of an impairment or other circumstances that are likely to interfere with normal growth and development or with the capacity to learn" (114).

International Classification of Impairments, Disabilities and Handicaps (ICIDH) - First published by WHO in 1980, this is an attempt to produce a systematic taxonomy of the consequences of injury and disease.

An Impairment is defined as "any loss or abnormality of psychological, physiological, or anatomical structure or function". Impairments are disturbances at the level of the organ and include defect, loss of limb, organ or other body structure and defects or loss of mental function. A disability is defined as "any restriction or lack (resulting from an impairment) of ability to perform an activity in a manner or within the range considered normal for a human being". The term disability reflects the consequences of impairment in terms of functional performance and activity by the individual; disability thus represents disturbance at the level of the person.

SCHOOL HEALTH SERVICE
A handicap is defined as a disadvantage for a given individual, resulting from an impairment or a disability, that limits or prevents the fulfilment of a role that is normal (depending on age, sex, and social and cultural practice) for that individual. The term handicap thus reflects interaction with and adaptation to the individual’s surroundings.

Handicap may be intrinsic or extrinsic. For example, blindness is an intrinsic handicap, and loss of parents is an extrinsic handicap. One handicap can give rise to further handicaps and the terms “primary” and “secondary” are used to denote this relationship. Blindness is a primary handicap; it can lead to poverty, which will be secondary handicap.

Extent of the problem

Nearly 83 million of the world’s population are estimated to be mentally retarded, with 41 million having long-term or permanent disability. It ranks fourth in the list of leading causes of disability. Hearing loss (41 decibels and above) over the age of 3 is estimated to affect 42 million people, ranking 3rd in the list. Disability resulting from poliomyelitis has affected about 10 million people (42). It is difficult to state how many people are mentally retarded in India as the census estimates do not cover mental handicap. About 16.15 million persons (1.9 per cent of the population) suffer from some or the other physical disability in the country. About 3 per cent child population in 1–14 years age group is affected by developmental delays (115).

Classification

It is usual to classify handicapped children into the following groups:

1. Physically handicapped
2. Mentally handicapped
3. Socially handicapped

1. Physically handicapped children

This category includes children who are blind, deaf and mute; those with hare-lip, cleft palate, talipes; and the ‘creepers’—e.g., resulting from polio, cerebral palsy, congenital heart disease, road accidents, burns, injuries, etc. These conditions fall into three broad causative groups:
(a) birth defects (b) infections, and (c) accidents. These are all preventable to a large extent through adequate prenatal, natal, postnatal services, and genetic counselling.

2. Mentally handicapped children

Mental handicap is the present term used for mental retardation. It is a condition of sub-average intellectual function combined with deficits in adaptive behaviour. Terms which were previously used such as idiot, moron and imbecile are now discarded. At least 2 per cent of India’s population is said to be suffering from some kind of mental disability (116).

Causes

Mental handicap has many causes. These may be genetic, or environmental and include prenatal as well as postnatal causes. The possible and earliest time to recognize the problem of mental retardation is to look for any delayed milestones and development.

The known causative factors include the following:
(a) Genetic conditions: Down’s syndrome, Klippel-Feil syndrome, PKU, Tay-Sachs disease, galactosaemia, congenital hypothyroidism involving both single and multiple gene action, and chromosomal abnormalities.
(b) Antenatal factors: These comprise neural tube defects, Rh incompatibility, certain infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), drugs and irradiation.
(c) Perinatal factors: These include birth injuries, hypoxia and cerebral palsy.
(d) Postnatal factors: Head injuries, accidents, encephalitis, poisoning and chemical agents such as lead and mercury poisoning may result in mental retardation.
(e) Miscellaneous: Maternal malnutrition, protein-energy malnutrition, iodine deficiency ( endemic goitre), consanguineous marriages, pregnancy after the age of 40 (late marriages) are all known to be associated with mental retardation.

Categories of mental retardation

Psychologists have used the concept of IQ to classify the degree of mental retardation. The IQ scores rest on the assumption that intelligence distribution in the general population follows the normal or Gaussian curve, with a mean of 100. The half of the general population achieve scores above 100, and one half below. The lower 3 per cent or so of the population achieve scores of 70 or less. They are usually considered to be mentally retarded. The WHO gave the following classification of mental retardation:

| Mild mental retardation | IQ 50–70 |
| Moderate mental retardation | IQ 35–49 |
| Severe mental retardation | IQ 20–34 |
| Profound and mental retardation | IQ under 20 |

Children scoring above 70 are no longer described as mentally handicapped. The number of mild cases far exceed the severe and profound cases. English statistics which have been widely quoted suggest that, among 100 mentally handicapped persons, the following proportion will be found: 70 mild, 20 moderate and 5 severe cases. In other words, a very great majority of cases of mental handicap are of the mild type and potentially capable of being taught to make a fairly adequate social adaptation in appropriate circumstances (11;

Severe mental retardation is uncommon. The great majority of severely handicapped children remain more or less dependant throughout life. Mental retardation often involves psychiatric disturbances. It has been stressed that the IQ range suggested must not be applied too rigidly. IQ level is not necessarily constant during the individual’s life span.

3. Socially handicapped children

A “socially handicapped child” may be defined as a child whose opportunities for a healthy personality development and a full unfolding of potentialities are hampered by certain elements in his social environment such as parental inadequacy, environmental deprivation (i.e., lack of stimulation of learning process), and emotional disturbances. Such children would include children who are orphaned either due to death or loss of parents; neglected and destitute children; those who are exploited or victimized; and, delinquent children. It may be pointed out that a child who is physically or mentally handicapped also meets with social handicaps to the extent to which he is subject to social rejection or misunderstanding and cannot make use of the normal value of social fulfilment.
Approaches to prevention

One of the objectives of Mother and Child Health Services is the prevention of handicapping conditions, and the early management of illness to prevent crippling sequelae.

1. Primary prevention

The ideal is to prevent the handicap from occurring through the application of preventive measures during preconceptional, prenatal and intranatal periods and during infancy, childhood and adolescence. The approaches in primary prevention include (a) Genetic counselling. The optimum maternal age for producing normal babies is between 20 and 30 years. After the age of 30 or 35 years, there is a greater chance of producing a genetically abnormal child, especially one with Down's syndrome. The mother should be advised accordingly. In some communities consanguineous marriages are common. The incidence of such marriage should be reduced through educational efforts. (b) At-risk approach: People "at-risk" of transmitting inherited diseases (e.g., chromosomal or sex-linked diseases) should be identified. They should be offered all the investigations currently available and should have competent advice about future risks. (c) Immunization: In India, the main cause of disability is poliomyelitis which is preventable by immunization (118). Immunization against other diseases such as rubella should also be considered. (d) Nutrition: Proper nutrition of the expectant mother is important for the welfare of the unborn child, especially to reduce the incidence of prematurity which is associated with mental handicaps. (e) Others: These include health care of mothers and children through prenatal, natal and postnatal periods; avoidance of infectious diseases, potentially teratogenic drugs, X-rays and smoking; special care of high risk women especially during labour, and accident prevention. The Medical Termination of Pregnancy Act of 1971 allows abortion of the foetus which may be seriously handicapped. In short, the obstetrician has a major role to play in reducing the frequency of handicaps in the population.

2. Secondary prevention

The broad objective for all children whatever their condition or problem is to bring them as close to normality as possible — physically, mentally and socially. This will involve: (a) Early diagnosis of handicap: Parents themselves have the responsibility to bring the child to paediatrician and seek advice. Investigation of the child requires full history, assessment of the degree of handicap and perhaps special investigations including the natural potentialities of the child. This should be done through MCH and School Health Services and such other agencies. (b) Treatment: Handicapped children need specialized treatment facilities such as physiotherapy, (the deformities are corrected, the weakened muscles are given exercise as in polio, infrared ways, diathermy etc.); occupational therapy (the child is taught, according to his ability and taste, things like music, painting, weaving, woodwork, pottery, basket making etc.); speech therapy (the child is trained to talk normally); and prosthetics (provision of artificial limbs; hearing aids and other equipment). The modern term for this branch of medicine is "Physical Medicine and Rehabilitation". The purpose of treatment is to improve the physical condition of the patient. (c) Training and education: the handicapped child is trained for an independent living. This is called "vocational guidance". He is trained to "work with what is left", so that he is not a burden on others. In India, there are over 150 schools and institutions for the handicapped. The following are some of the important ones: (1) Occupational Therapy School, Mumbai. (2) Physical Therapy School, Mumbai. (3) "The Horizon" Happy School, Nagpur. (4) Pali Institute of Physical Medicine and Rehabilitation, Mumbai. (5) Institute of Physical Medicine and Rehabilitation, Christian Medical College, Vellore. (6) Occupational Therapy College, New Delhi. Beside these, there are schools for the blind, deaf, and special hospitals and wards for crippled children. Institutional care of the handicapped children is being replaced by various social support measures and services, enabling families to assume a larger share of rehabilitation within the family cycle (36).

The mentally handicapped children can be helped to reach their optimal capacity through attention to the following: (a) they should be given valued work, patience and tolerance, besides discipline (b) their natural potentials should be identified, and the child must be helped to develop in that direction in all possible manner. The mentally handicapped require attention from diverse disciplines such as medicine, psychology, education, rehabilitation and social welfare. Taking into account the gravity of the problem, the Ministry of Social Welfare, Govt. of India, has set-up the National Institute for Mentally Handicapped (NIMH) in 1984 at Secunderabad. It has Regional Branches at Mumbai, New Delhi and Kolkata. The NIMH serves as an apex organization for developing appropriate models for the mentally handicapped (116).

Apart from NIMH, 3 other premier National Institutes are working in specific disabilities: (a) All Vavas-Jung National Institute for Orthopedically Handicapped (NJNOH) at Tiruchirappalli with Regional branches at New Delhi, Kolkata and Secunderabad, (b) National Institute for the Visually Handicapped, Dehradun with Regional branches at Chennai, (c) National Institute for the Orthopedically Handicapped, Kolkata. Apart from developing models for care and services, these institutions conduct research, promote human resource development, crises management, education, placement and employment, development and supply of appropriate aids and appliances, and documentation and dissemination of information (115).

In India the Ministry of Social Welfare operates through five major schemes of assistance to voluntary organizations providing services to disabled persons. These are: (a) Assistance to voluntary organizations for the disabled: Assistance up to 90 per cent in urban and 95 per cent in rural areas is given to NGOs for education, training and rehabilitation of the disabled; for rehabilitation of people recovering from mental illness; emphasis on nutritional guidance and training; liaison with nearest psychiatric centre or hospital; provision for Hals-way Hospitals. (b) Assistance for aids and appliances: Aids and appliances up to Rs 3,600 are provided to people with disabilities free, if the monthly income is up to Rs 1,200, and at 50 per cent cost if the monthly income is between Rs 1,201 to 2,500. (c) Assistance to voluntary organizations for rehabilitation of leprosy-cured persons: Assistance to voluntary organization working for leprosy-cured persons is given up to 90 per cent for public education and awareness, early intervention, educational and vocational training, economic rehabilitation and social integration. (d) Development in the field of cerebral palsy and mental retardation: For manpower training of professionals and also
for developing organizational infrastructure such as class
rooms/library/hall in the field of cerebral palsy and mental
retardation. (e) Assistance to voluntary organization or
establishment of special schools: For setting up special
schools NGOs receive grants up to 90 per cent. Preference is
given for opening schools in new districts and upgrading of
existing schools.
of India has introduced a comprehensive Bill in the
Parliament known as Persons with disabilities (equal
opportunities, protection of right and full participation) Bill
1995. It deals with preventive and promotional aspects of
rehabilitation.
In considering the management of the socially
handicapped child, we must remember that such children
are normal in their needs and development. Their needs
should be identified and met. The children Act, 1960
provides for the "care, protection, maintenance, welfare,
training, education and rehabilitation" of the socially
handicapped children.
Lastly, we need to strengthen the family. The family is the
most effective bulwark to prevent children from becoming
socially handicapped. There were times when the
handicapped child was considered a liability to the parents
and to the society. All over the world, there is an awakening
that handicapped children can and must be helped to make
their lives as happy and useful as possible.

BEHAVIOUR PROBLEMS

The behaviour problems in children may be classified as
below:
(a) Problems antisocial in nature: Stealing, lying,
gambling, cruelty, sexual offences, destructiveness.
(b) Habit disorders: Thumb sucking, nail-biting, bed-
walking, enuresis.
(c) Personality disorders: Jealousy, temper-tantrums,
timidity, shyness, day-dreaming, fears and anxieties,
unsociability, hysterical manifestations.
(d) Psychosomatic complaints: Tumors, headache,
asthma, depression, delusion, hallucinations.
(e) Educational difficulties: Backwardness in studies,
school phobia, school failure, etc.

Some of the behaviour disorders are due to mental
deficiency; some are due to organic disease and some due to
failure is adjustment to external environment. The answer to
these problems lies in improvement of living conditions,
better social environment and education.

JUVENILE DELINQUENCY

The Children Act, 1960 in India defines delinquent as
"a child who has committed an offence". Juvenile means a
boy who has not attained the age of 16 years and a girl who
has not attained the age of 15 years. In a broad sense,
delinquency is not merely "juvenile crime". It embraces all
deviations from normal youthful behaviour and includes the
incorrigible, ungovernable, habitually disobedient and those
who desert their homes and mix with immoral people, those
with behaviour problems and indulge in antisocial practices.

INCIDENCE: In the United States it is reported that 2
per cent of children between 7 and 17 years attend
juvenile courts. Comparable statistics are not available in
India to denote the size of the problem, but it is agreed that
juvenile delinquency is on the increase in India during the
past few decades, due to changes in the cultural pattern of
the people, urbanization and industrialization. The
highest incidence is found in districts of 15 and above.
The incidence among boys is 4 to 5 times more than
among girls.

CAUSES: (1) Biological causes: Certain biological causes
such as hereditary defects, feeble-mindedness, physical
defects and glandular imbalance may be at the bottom of
juvenile delinquency. Recent studies indicate that
chromosome anomaly might be associated with a tendency
for delinquency and crime. A survey of criminal patients in
Scotland and elsewhere demonstrated such a link - some of
the patients having an extra Y chromosome. The XXY men
suffer from severe disturbance of the whole personality (119).
(2) Social causes: Among the social causes may be
mentioned broken homes, e.g., death of parents, separation
of parents, step mothers and disturbed home conditions e.g.,
poverty, alcoholism, parental neglect, ignorance about child
care, too many children, etc. (3) Other causes: Absence of
recreation facilities, cheap recreation, sex-thrillers,
urbanization and industrialization, cinemas and television,
slum-dwelling, etc.

PREVENTIVE MEASURES: (1) Improvement of family
life: A well adjusted family can stem the tide of delinquency.
Parents should be prepared for parenthood. The needs of
children should be appreciated and met. (2) Schooling: The
school comes next to home in the community in ordering the
behaviour of children. There should be a healthy teacher-
pupil relationship. The school teacher can play an important
part by detecting early signs of saliadjustment. (3) Social
welfare services: These comprise recreation facilities,
pawn-counselling, child guidance, educational facilities
and adequate general health services.

Children in difficult circumstances (64)

In a globalized economy, the increased vulnerability of
some children due to their identity, and/or their socio-
economic and geo-political circumstances calls for more
focused attention as well as coordination of social and
economic policies and monitoring of child impact. Besides
being victims of globalization, these children may be barred
from benefits meant for all children simply because they
belong to a group or community with difficulties of access.
These barriers must be overcome.

Over the years, some children have been categorized as
children in difficult circumstances and these categorizations
include:

- Homeless children (pavement dwellers, displaced/ evicted, etc.)
- Orphaned or abandoned children
- Children whose parents cannot or are not able to take
care of them
- Children separated from parents
- Migrant and refugee children
- Street children
- Working children
- Trafficked children
- Children in bondage
- Children in prostitution
- Children of sex workers/prostitutes/sexual minorities
- Children of prisoners
- Children affected by conflict
- Children affected by natural disasters
- Children affected by HIV/AIDS
- Children suffering from terminal diseases
- The girl child
- Children with disabilities and related special needs
- Children belonging to the ethnic and religious minorities, and other minority communities, and those belonging to the Scheduled Castes and Scheduled Tribes
- Children in institutional care, be it in state-run institutions or religious and other charitable institutions
- Children in conflict with law (those who commit crimes)
- Children who are victims of crime

For the first time in the history of planning for children, India has adopted a clear understanding and definition of the child in the NPCA 2005. The NPCA definition of the child as a person upto the age of 18 years and its clear declaration that 'all rights apply to all age-groups, including before birth' reiterates the 1974 National Policy mandate that the State takes responsibility for children 'both before and after birth,' and the child's interests are to receive paramount attention. This national reaffirmation must set the frame for future planning and intervention to secure the well-being of all children of the country and provide them a caring and protective environment.

Battered baby syndrome

It has been defined as "a clinical condition in young children, usually under 3 years of age who have received non-accidental wholly inexcusable violence or injury, on one or more occasions, including minimal as well as severe fatal trauma, for what is often the most trivial provocation, by the hands of an adult in a position of trust, generally a parent, guardian or foster parent. In addition to physical injury, there may be deprivation of nutrition, care and affection in circumstances which indicate that such deprivation is not accidental'.

Battered baby syndrome has been found in all strata of society. Its incidence is not known. So far as sequelae are concerned, the most worrying is the risk of mental and neurological complications. Thus it has been tentatively suggested that 10-15 percent of cases of cerebral palsy and almost double that proportion of the new mentally retarded children each year may be the result of the battered baby syndrome.

Girl child and gender bias (64)

Gender biases pose a specific threat to girl children across the social and economic strata. For a girl child, life is a constant fight for survival, growth and development from the time she is conceived till she attains 18 years. The life chart of a girl child and the many life threatening problems she faces are as follows:

- Being unwanted, risk of prenatal detection
- Foeticide and infanticide
- Infant mortality
- Discrimination in breast-feeding and infant food
- Neglect of health (immunization)
- Discrimination in access to food
- Poorer health attention and poorer access to health care; high risk of nutritional anaemia
- Discrimination in overall treatment, parental care; expression of value and worth
- Vitamin and micro-nutrient deficiencies
- Early definition and imposition of 'suitable' roles; limits on permitted learning and play activities
- Child marriages in some areas of country
- Household/near-home sexual abuse
- If enrolled in school, less time for learning
- Assignment of domestic duties, minor small domestic chores
- Malnutrition and anaemia
- Health problems like diarrhoea
- Iodine and Vitamin A deficiency
- Low school enrolment, school drop outs
- Vulnerable to trafficking, child labour, child marriage
- Abuse, exploitation and violence
- Increasing domestic duties/workload
- Looking after siblings
- Restrictions on mobility, play
- Poor health, poor health attention
- High risk/high levels of anaemia
- Frequent illness due to malnutrition and micro-nutrient deficiency
- Child marriage
- High-risk/incidence of early child-bearing related morbidity/mortality
- Becoming a 'child-mother', health risks and burden of child care
- Denied information, mobility, access to services
- Low literacy/learning level
- Early and frequent pregnancy coupled with abortions
- Marital and domestic violence
- Dowry harassment, desertion, polygamy, divorce
- Child labour, trafficking
- STDs and HIV/AIDS
- Unpaid and unrecognized work, and drudgery
- No voice either in home or society.

It is evident from the text above that age-specific and setting-specific interventions have to be put in place for appropriate response to the above problems, highlighting the inter-sectoral nature of actions required.
Protecting girl children in India will not be easy. The nation cannot any longer afford the cost of hoping that society will change its mindset on its own, in a situation where pervasive negative attitudes towards women are being reflected on girl children, to the extent of denying them life itself.

The well-being of daughters in the community must become the subject of government monitoring (with NGO assistance if appropriate), covering every age and stage of childhood. Such vigilance must apply to all stages of a girl child’s childhood. Ponchayats, gram sabhas and local self-government bodies should be brought into this benevolent surveillance.

The specific goals for girls in the National Plan of Action for Children 2005

- Assurance of equality of status for girl child as an individual and a citizen in her own right through promotion of special opportunities for her growth and development.
- To ensure survival, development and protection of the girl child and to create an environment wherein she lives a life of dignity with full opportunity for choice and development.
- To stop sex selection, female foeticide and infanticide.
- To eliminate child marriages.
- To ensure the girl child’s security and protect her from abuse, exploitation, victimisation and all other forms of violence.
- To protect the girl child from depravities and neglect and to ensure to the girl child an equal share of care and resources in the home and community, and equal access to services.
- To take measures to protect girl children from any treatment which undermines their self-esteem, and causes their exclusion from social mainstream and also to break down persistent gender stereotype.
- To eliminate all obstacles that prevent girls from full enjoyment of human rights and fundamental freedom including equal rights in succession and inheritance.
- To ensure equal opportunity for free and compulsory elementary education to all girls.
- Health and nutrition.

Child abuse

In ancient times, general opinion accepted that children could be beaten and abused. The industrial exploitation of children after the Middle Ages was commonplace, with no widespread protest. The prevalence of cruelty to children, as to animal, was beginning to be a matter of public concern in the 18th century, but birth and care lingered on and were brandished respectively at home and at school, well into the present century.

The broader concept of child abuse (which includes battering) is of recent origin. Its recognition by the caring professions has brought a spate of conferences, symposia and publications. The concept itself has been broadened to include not only physical violence, but sexual abuse, sexual and emotional maltreatment, neglect, deprivation and lack of opportunity. The consequences of physical battering – death, blindness, mental and emotional retardation, stunting of growth – is only one part of the whole picture of child abuse. Some contributory factors of child abuse are poverty, alcohol and other drug abuse, loneliness, immaturity and a host of other factors. Many causes are embedded in the family and in its function of child rearing.

During the year 1991 there were one million cases of child abuse and neglect in the USA, i.e., an incidence of about 2 per cent children being subjected to physical and/or sexual abuse. Countries around the world report comparable figures (220).

Studies carried out throughout the past two decades have shown that the provision of supportive home visitors, either public health nurse or trained lay people, to families who are at risk of using violence against children can prevent the abuse from happening. However, we have not yet reached a similar level of confidence about our ability to prevent the sexual abuse of children, which is also a worldwide phenomenon.

Suggested remedial measures include increased legal help, more case workers, educating young people to postpone having children until they are sufficiently mature to be adequate parents. Attempt to strengthen the individual and his family may prove helpful. The problem is complex and reflects merely one facet of the larger issue of violence in the home and in society at large (221).

Street children

A large number of children live and work on the streets, a high proportion without any family support, particularly in the megacities of the developing world. They are at high risk of malnutrition, tuberculosis, STIs including HIV, parental and worse infestation and skin diseases. Both sexes are highly vulnerable to drug abuse and criminal exploitation.

Most street children describe major losses in their lives. Many have lost family members through diseases, natural or manmade disasters, or may be by-product of war and riots.

Although poverty and rapid urbanization are major contributing factors to the problem, many claim that physical and sexual abuse were the reason for their leaving home.

Recent global estimates place their number at as many as 100 million. There may be 40 million in Latin America, 25 million in Asia and 10 million in Africa, with about 25 million in other areas including the developed world. In 1993 WHO launched an innovative project to study links between street children and substance abuse. The study noted regular use of alcohol and other drugs by a major proportion of street children. Often the lives of street children are intimately enmeshed with the illegal drug industry. Street children are used in the production and marketing of cocaine and the trafficking of cannabis and heroin (42).

There are particular problems in the provision of health and welfare services to street children, with regard not only to health care but also to housing, educational opportunities and employment. The rehabilitation of these children should be taken up by the government and non-government voluntary agencies.

The “Integrated Programme for Street Children” without homes and families was launched to prevent destitution of children and provide facilities for their withdrawal from life on the streets. During 2008-09 the scheme was merged to Integrated Child Protection Scheme. Under the scheme NGOs are given financial support to run 24 hour shelters and
provide food, clothing, non-formal education, recreation, counselling, guidance and referral services for children. The other components of the scheme include enrolment in schools, vocational training, occupational placement, mobilizing preventive health services and reducing incidence of drug substance abuse, HIV/AIDS etc. (60).

Refugee and displaced children (122)

At the end of 2004, roughly 48 per cent of all refugees worldwide were children.

During the same year, the total number of people displaced within their own countries by conflict or human rights violations amounted to roughly 25 million.

Refugee and internally displaced children face many risks, given the violence and uncertainty surrounding both their flight and their lives in the country and/or place of asylum. They may become separated from their families, lose their homes and find themselves living in poor conditions that jeopardize their health and education.

Displacement complicates both registration and the issuance of travel documents, thereby compromising displaced persons' right to identity. Both refugees and internally displaced people may have been forced to leave their homes without proper documentation, making it difficult to establish their identities. They may, therefore, be unable to prove their right to receive basic social services, such as education or health care, or to work in a different part of the country.

The loss of family protection, and inadequate resources to address the needs and challenges that refugee and internally displaced children face, can leave them at significant risk of recruitment by armed groups and forces, abuse and sexual exploitation. Girls are especially at risk of abduction, trafficking and sexual violence, including rape used as a weapon of war.

Orphaned children are much more vulnerable to protection violations. The death of a parent, in situations where no adequate alternative care systems are in place, opens up a protection gap. Children living on their own are at much greater risk of abuse and exploitation. Assessments by the International Committee of the Red Cross (ICRC) have found that orphaned children are much more likely than non-orphaned children to be working in commercial agriculture, as street vendors, in domestic service and in the sex trade.

Primary responsibility for both refugee and displaced children lies with national governments. However, the Office of the United Nations High Commissioner for Refugees (UNHCR) has a mandate to assist internally displaced people. Displacement is a result of armed conflict and internal violence.

Child labour and child exploitation

A sizeable number of growing children are poor socio-economic class especially in rural areas are known to be engaged in child labour. Studies have shown that labour at a very young age can have dire consequences on the child's development, both physical and mental. Child labourers always had lower growth and health status compared to their non-working counterparts, besides exposure to occupational hazards at a very young stage in their lives. The Declaration of the Rights of the Child and the own Constitution has laid down that childhood and youth should be protected against exploitation. In 1973, the ILO passed a convention establishing 15 as the minimum work age for some sectors while permitting light work from age 13, provided that such work was unlikely to harm child's health, morals and safety or prejudice his school attendance (123).

Surveys by International Labour Organization (ILO) in 1990 found that over 79 million children under the age of 10 years were obliged to work. In some cases children as young as 5 years have been reported to be in paid employment. Africa and Asia dominate the data on child labour. The scenario has not changed much to the present time.

According to ILO, forced child labour is present in all regions and kinds of economy. For the most part, there is not much statistical data on forced child labour as a widespread awareness among society at large that forced labour is a problem. Children in domestic service are the most vulnerable child labourers. Their work is performed within individual homes, removed from public scrutiny and their conditions of life and labour are entirely dependent on the whims of their employers. The number of children involved in domestic service around the world is unquantifiable because of the hidden nature of the work, but it certainly runs into millions. Many of these children are girls, and in many countries domestic service is seen as the only avenue of employment for a young girl, though in some places, such as Nepal and South Africa, boys are more likely to be domestic workers than girls. Children engaged in domestic service are generally paid little or nothing over and above food and lodging. In addition, children in domestic service are especially susceptible to physical and psychological harm. Many are forced to undertake tasks that are completely inappropriate for their age and physical strength. Another form of forced labour is debt bondage, whatever the origin of the debt, it leaves children under complete control of a money lender in a state little distinguishable from slavery.

India fosters the largest number of child labour in the world. Child labour contributes about 20 per cent of India's GDP. Child workers work for 12 hours at an average every day (124). Jammu and Kashmir has the highest percentage of child labour, where children are mainly engaged in carpet weaving industry (125). The other fields where child labour is used is in agriculture, plantations, mining, building construction, brick-making, garbage picking, cashew descaling and processing, cloth printing, dyeing and weaving etc.

In India, various items of health and social legislation have been enacted to protect the health, safety and welfare of working children below the age of 15 years.

The Child Labour (Protection and Regulation) Act, 1986

Except in the process of family-based work or recognized school-based activities, children are not permitted to work in occupations concerned with:

- Passenger, goods main transport by railways
- Carpet weaving
- Cinder picking, cleaning of ash pits
- Cement manufacturing
- Building construction operations
Child labour is rooted in poverty, unemployment and lack of education. A great deal of effort is needed to eliminate these basic causes. It is felt that instead of proliferating the laws relating to children, all the statutory provisions of the various Acts relating to children should be grouped in one comprehensive code of children. It is not feasible to abolish child labour entirely in the present context, but it is expedient to protect such children against abuse, exploitation and health hazards, and regulate the conditions of work in occupations where child labour is permitted.

**Child trafficking (122)**

Trafficking of children takes many different forms. Some children are forcibly abducted, others are tricked and still others opt to let themselves be trafficked by promise of earnings, but not suspecting the level of exploitation they will suffer at the other end of the recruiting chain. Trafficking always involves journeys, whether within the country or across the international border. The relocation takes children away from their families, communities and support net-work, leaving them isolated and utterly vulnerable to exploitation. Collecting data about these children is very difficult. It is estimated that trafficking affects about 1.2 million children each year. Fig. 18 shows children in worst forms of child labour and exploitation.

![Diagram showing child trafficking](image)

**FIG. 18**

Children in unconditional worst forms* of child labour and exploitation

* Unconditional worst forms of child labour: These forms of labour correspond to those outlined in Article 3 of the International Labour Organization Convention No.182

Though the trafficking of children is a shadowy practice, some dominant regional patterns are identifiable. In West and Central Africa, children are "slaved" in a marginal position within other families. This practice is being used to exploit children both within and outside home. Children are also trafficked into plantations and mines, and in those countries affected by conflict, they are directly abducted by militias. In East Asia and Pacific, most trafficking is into child prostitution, though some children are also recruited for industrial and agricultural work. In South Asia, trafficking forms most of immense child labour problem in the subcontinent, often related to debt bondage. In addition, significant number of children are trafficked for other purposes, including into prostitution, caret and garment factories, construction projects and begging. In Europe, children are mainly trafficked from east to west, reflecting the demand for cheap labour and child prostitution in richer countries of the continent. Children are also used as unskilled labour and in the entertainment sector.

An estimated 8.4 million children work under terrible circumstances and are forced into bondage or other forms of slavery (Fig. 18).

Making children safe requires creating a protective environment for them. The key elements of a protective environment include:

- Strengthening the capacity of families and communities to care for and protect children.
- Government's commitment to child protection by providing budgetary support and social welfare policies targeted at the most excluded and invisible children.
- Ratification and implementation of legislation, both national and international, concerning children's rights and protection.
- Prosecution of perpetrators of crimes against children, and avoidance of criminalizing child victims.
- An open discussion by civil society and the media of attitudes, prejudices, beliefs and practices that facilitate or lead to abuses.
- Ensuring that children know their rights, are encouraged to express them and are given vital life skills and information to protect themselves from abuse and exploitation.
- Availability of basic social services to all children without discrimination.
- Monitoring, transparent reporting and oversight of abuses and exploitation.

The key to building the protective environment is the responsibility of members of the society, by ensuring that children are not exploited. While families and the State have the primary responsibility for protecting children, ongoing and sustained efforts by individuals and organizations at all levels, are essential to break patterns of abuse.

**UJJAWALA**: "Ujjwala", a comprehensive scheme to combat trafficking was launched in India by the Ministry of Women and Child Development on 4th December, 2007 and is being implemented mainly through NGOs. The scheme has five components of prevention, rescue, rehabilitation, reintegration and repatriation of victims.
trafficked for commercial sexual exploitation. Some of the provisions under the scheme are (65) :
(1) Formations of community vigilance groups, adolescents groups, awareness creation and preparation of IEC materials;
(2) Safe withdrawal of victims from the place of exploitation;
(3) Rehabilitation of victims by providing them safe shelter, basic amenities, medical care, legal aid, vocational training and employment.
(4) Re-integration of victims into society; and
(5) Provide support to cross-border victims for their safe repatriation to the country of origin.
Child marriage
Early marriage is a long-established custom in India. As early as 1929, the Sharda Act was enacted forbidding the practice of child marriages. Impetus of the spread of literacy and legislations prohibiting early marriages, child marriages are still in vogue in the country, particularly in Rajasthan, Madhya Pradesh and Uttar Pradesh, where substantial proportion of marriages take place when the girl is around 15 years of age (126). The census data reveal that prior to 1951, the average age at marriage for girls in India was 13 years. There is however a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age of marriage from 15 to 18 years for girls; and from 18 to 21 years for boys. Studies indicate that in many states, the mean age at marriage for girls has already moved into 19 years and 24 years for the boys. The Prohibition of Child Marriage Act, 2006 (PCMA) was enacted repealing workshops; The Prohibition of Child Marriage Restraint Act of 1929 in order to prohibit child marriage rather than only restraining them. PCMA has been enforced with effect from 1st November, 2007. It makes child marriage an offence and makes provision for punishment for those conducting / abetting /promoting / permitting the marriage (65).
The age at which the girl marries and enters the reproduction period of life has a great impact on her fertility. Girls who marry before the age of 18 give birth to larger number of children than those who married later. It is estimated that if the marriages were postponed from the age of 16 to 20-21, the number of births would decrease by 20-30 per cent.
Child guidance clinic
The first child guidance clinic was started in Chicago in 1909 and ever since, they have grown in number and complexity throughout the world. Originally intended to deal with problems of juvenile delinquency, child guidance clinics deal with all children or adolescents who for one reason or other, are not fully adjusted to their environment. The object of child guidance is to free the child from the possibility of becoming neurotics and psychotics in later life.
Team work - Child guidance is a team work job – the team comprising of a psychiatrist, clinical psychologist, educational psychologist, psychiatric social workers, public health nurses, pediatrician, speech therapist, occupational therapist and a neurologist. The psychiatrist is the central figure and is helped by the others in arriving at a correct diagnosis and formulating the line of treatment.
Services : The paediatrician takes care of the physical health of the child. The core of therapy is psychotherapy in order to restore positive feelings of security in the child. To achieve this, many methods are employed, e.g., play therapy, counselling, suggestions, change in the physical environment, easing of parental tensions, reconstruction of parental attitudes, etc. The child guidance clinics operate on the premise that if sound foundations of mental health are laid in childhood and adolescence, the same will continue into adulthood.
Child placement
(1) ORPHANAGES : Children who have no home or who for some reason could not be cared for by their parents are placed in orphanages. Scientific studies of human behaviour have revealed that mass care of infants and children in large institutions is undesirable. In such institutions the child has little opportunity for the child to experience the warmth and intimacy of family life, to develop emotional security and to participate in activities that would help him to become an adequate citizen. (2) FOSTER HOMES : Fostering is an arrangement whereby a child lives, usually on a temporary basis, with an extended or unrelated family member. Such an arrangement ensures that the birth parents do not lose any of their parental rights or responsibilities. This arrangement caters to children who are not legally free for adoption, and whose parents are unable to care for them due to illness, death or desertion by one parent, or any other crisis. The aim is to eventually re-unite the child with his/her birth family. The foster home resembles the family circumstances improve (65).
(3) ADOPTION : In addition to the more or less temporary placement of children in foster or boarding homes, children are legally adopted. Legal adoption occurs upon the consent of the child and adoptive parents, rights and responsibilities similar to that of natural parents. The laws of adoption vary from country to country. The relevant law in India is the "Hindu Adoption and Maintenance Act, 1956". (4) BOSTRALS : Boys over 16 years who are too difficult to be handled in a certified school or who have misbehaved there, are sent to a Bostral. This institution falls in a category between a certified school and an adult prison. A Bostral sentence which is usually for three years, is regarded as a method of training and reformation. There are about six Bostrals for boys in India but none for girls. Bostrals do not come under the Children Act but are governed by the State Inspector General of Prisons (125). (5) REMAND HOMES : In the remand home, the child is placed under the care of doctors, psychiatrists and other trained personnel. Every effort is made to improve the mental and physical well-being of the child. Elementary schooling is given, various arts and crafts are taught, games are played and other recreational activities are arranged.
The CHILDREN ACT, 1960
The Children Act, 1960 in India (amended in 1977) provides for the care, rehabilitation, welfare, training, education and rehabilitation of the delinquent child. It covers the neglected and destitute, socially handicapped, uncontrollable, victimized and delinquent children. In Article 39 (f) the Constitution of India provides that “the state shall in particular direct its policy towards securing that childhood and youth are protected against moral and material abandonment.”
JUVENILE JUSTICE ACT 1996

With the implementation of the Juvenile Justice Act, 1996, all Children's Acts applicable in different parts of the country have been repealed. The new Act, apart from rectifying the inadequacies of Children's Act, provides a comprehensive scheme for care, protection, treatment, development and rehabilitation of delinquent juveniles. The new Act has come into force from 2nd Oct 1987. Some of the important features of the Act are:

- It provides a uniform legal framework for juvenile justice system so as to ensure that no child under any circumstances is put in jail or police lock-up;
- It envisages a special approach towards prevention and treatment of juvenile delinquency in keeping with the developmental needs of children;
- It establishes norms and standards for administration of juvenile justice in terms of investigation, care, treatment and rehabilitation;
- It lays down appropriate linkages and coordination between the formal system of juvenile justice and voluntary organizations. It specifically defines the roles and responsibilities of both.

Juvenile Justice Act 2000 (64)

Juvenile Justice (Care and Protection of Children) Act, 2000 (now Amendment Act 2006) is an Act to consolidate and amend the law relating to juveniles in conflict with law and children in need of care and protection, by providing for proper care, protection and treatment by catering to their development needs, and by adopting a child-friendly approach in the adjudication and disposal of matters in the best interest of children and for their ultimate rehabilitation. The Act defines a juvenile/child as a person who has not completed the age of 18 years. It has two separate chapters – one for juveniles in conflict with law and the other for children in need of care and protection. It also contains an exclusive chapter concerning rehabilitation and social reintegration of children. The Act defines Juvenile in conflict with law as a child who is alleged to have committed an offence and Children in need of care and protection broadly as children who are neglected, abused, abandoned, victim of any armed conflict or natural calamity amongst others. Offences committed against a child as listed in the Act, are cognizable and punishable under the provisions of this Act.

In order to implement its provisions and procedure, the Act provides for:
- Juvenile Justice Board;
- Child Welfare Committee;
- Institutional care through children's homes, observation homes, shelter homes, special homes and aftercare organizations;
- Non-institutional care through Adoption, Foster Care, Sponsorship Act and After Care;
- Special Juvenile Police Units;
- Juvenile Justice Fund;
- Central/State/District Advisory Boards;
- Selection Committee;
- Inspection Committee.

SOCIAL WELFARE PROGRAMMES

The various social welfare programmes for women and children in India may be broadly categorized under six heads:

1. Programmes for the welfare of women
2. Programme for the underprivileged children
3. Comprehensive programmes (both for women and children) for the maladjusted groups
4. Schemes for the physically handicapped persons
5. Programmes for the welfare of backward classes

CHILD WELFARE

Child welfare covers the entire spectrum of needs of children who by reason of handicapped – social, economic, physical or mental – are unable to avail of services provided by the community. Child welfare programmes thus seek to provide supportive services to the families of these children because one of the important responsibilities of the society and state is to assist the family in its natural obligations for the welfare of the children.

Child welfare services in their various facets are preventive, promotive, developmental and rehabilitative in nature. The problem is gigantic, and the resources available are only supplementary in nature and are designed to meet certain needs of the most deprived and vulnerable among the country’s child population. Attention is generally focussed on three categories of children in the poverty groups:

- children of working mothers;
- destitute children; and
- handicapped children.

CHILD WELFARE AGENCIES

The important child welfare agencies in India are:

1. Indian Council for Child Welfare (ICCW)
2. Central Social Welfare Board
3. Kasturba Gandhi Memorial Trust
4. Indian Red Cross Society

These agencies have got branches all over the country. They get financial aid from the government to operate child welfare services in the country. The following are some of their activities:

- DAY CARE SERVICES – This is for children of working mothers.
- Nursery schools
- BALAVIDAS and creches are set up to help the children of working mothers.
- Day care centres are mainly for infants and toddlers.
- HOLIDAY HOMES – These are organized for children in the age group of 7-12 years at hill stations and sea-side resorts. The children spend their holidays in a useful manner.
- RECREATION FACILITIES – These comprise organization of playcentres, public parks, children’s libraries, BAL BHAVANS, children’s films, national museums, hobby classes, etc. Besides the national agencies, the following international agencies are interested in child welfare:

INTEGRATED CHILD DEVELOPMENT SERVICES (ICDS)

Currently, the most important scheme in the field of child welfare is the ICDS scheme. The blue print for the scheme was prepared by the Department of Social Welfare in 1975. Considering the magnitude of the task, it was decided to take up an experimental basis 33 projects in the year 1975–76 in 4 urban, 10 rural and 10 tribal areas spread over 22 states and the Union Territory of Delhi. The projects were
sanctioned in October 1975. The Government of India decided to expand the project to cover 100 areas by 1978-79. Two major evaluations were conducted in 1978 and 1982. The positive results of these evaluations formed the basis for the governments' decision to accelerate the expansion of ICDS in 1982.

Prior to 2005–06, providing supplementary nutrition was the responsibility of the states and administrative cost was provided by the central government. Government of India has modified the cost sharing pattern under ICDS by giving aid of 50 per cent of the financial expenditure to the states/UTs.

The population norms for setting up of Anganwadi Centres (AWC) and Mini-AWC have been revised to cover all habitations by SC/ST/minorities. The revised norms are as follows (65):

<table>
<thead>
<tr>
<th>Project Type</th>
<th>Population Norms</th>
</tr>
</thead>
<tbody>
<tr>
<td>For AWCs in rural/urban projects</td>
<td>1 AWC for 400–800 population, 2 AWCs for 800–1600 population, 3 AWCs for 1600–2400 population. Thereafter one AWC for multiples of 900 population, for Mini-AWC, the norm is one mini-AWC for 150 to 400 population.</td>
</tr>
<tr>
<td>For tribal/remote/desert/hilly and other difficult areas</td>
<td>1 AWC for 300–800 population, 1 Mini – AWC for 150–300 population.</td>
</tr>
</tbody>
</table>

The ICDS seeks to lay a solid foundation for the development of the nation’s human resource by providing an integrated package of early childhood services. These consist of (1) supplementary nutrition (2) immunization (3) health check-up (4) medical referral services (5) nutrition and health education for women and (6) non-formal education of children up to the age of 6 years, and pregnant and nursing mothers in rural, urban, slums and tribal areas. ICDS scheme is designed both as a preventive and development effort. The services of immunization, health check-up and referral services are provided through public health infrastructure i.e., sub-centres, PHCs and CHCs. The services are provided concurrently.

**Objectives** (127)

The objectives of the ICDS scheme are:

- (a) to improve the nutritional and health status of children in the age group 0–6 years;
- (b) to lay the foundations for proper psychological, physical and social development of the child;
- (c) to reduce mortality and morbidity, malnutrition and school drop-out;
- (d) to achieve an effective coordination of policy and implementation among the various departments working for the promotion of child development; and
- (e) to enhance the capability of the mother and nutritional needs of the child through proper nutrition and health education.

To achieve the above objective the ICDS aims at providing the following package of services.

<table>
<thead>
<tr>

</tbody>
</table>

**Delivery of services**

1. **Supplementary nutrition**

   Supplementary nutrition is given to children below 6 years, and nursing and expectant mothers from low income group. The type of food depends upon local availability, type of beneficiary, location of the project etc. The aim is to supplement nutritional intake as follows (65):
   - a. each child 6–72 months of age to get 500 calories and 12–15 grams of protein (financial norm of Rs 4.00 per child per day);
   - b. Severely malnourished child 6–72 months to get 800 calories and 20–25 grams protein (financial norm of Rs 6.00 per child per day); and
   - c. Each pregnant and nursing woman to get 600 calories and 18–20 grams of protein (financial norm of Rs 5.06 per beneficiary per day).

Under the revised nutritional and feeding norms for supplementary nutrition, state governments/UTs have been mandated to provide more than one meal to the children who come to AWCs, which include providing a morning snack in the form of milk/banana/egg/seasonal fruit/micronutrient fortified food followed by a hot cooked meal. For children below 3 years of age, and pregnant and lactating mothers, "take home ration" is to be provided. All are eligible for availing of the services of ICDS, below poverty line is not a criteria for registration of beneficiaries. The scheme is universal.

**Supplementary nutrition is given 300 days in a year (127).** Adequate funds for supplementary nutrition is provided in the State Plan under Minimum Needs Programme. Children are weighed every month. Nutrition education and health education is given to mothers of children suffering from 1st degree of malnutrition.
Supplementary nutrition (therapeutic food) is given to children suffering from 2nd and 3rd degree malnutrition. Children suffering from 4th degree malnutrition are recommended hospitalization.

2. Nutrition and health education
Nutrition education and health education is given to all women in the age group 15–45 years, giving priority to nursing and expectant mothers. It is imparted by specially organized courses in village during home visits by anganwadi workers.

3. Immunization
Immunization of children against 6 vaccine preventable diseases is being done, while for expectant mothers, immunization against tetanus is recommended.

4. Health check-up
This includes (a) antenatal care of expectant mothers; (b) postnatal care of nursing mother and care of newborn infants; (c) care of children under 6 years of age. Besides immunization, expectant mothers are given iron and folic acid tablets along with protein supplements. A minimum of 3 physical examinations are done. High risk mothers are referred to appropriate institutions for special care.

The health care of children under 6 years of age consists of:
1. Record of weight and height of children at periodic intervals
2. Watch over milestones
3. Immunization
4. General check-up every 3-6 months to detect disease, malnutrition etc.
5. Treatment for disease like diarrhoea, dysentery, respiratory tract infections etc. which are widely prevalent.
6. Deworming
7. Prophylaxis against vitamin A deficiency and anaemia
8. Referral of serious cases to hospital has also been provided for.

Health records: Health records of the children, antenatal care and delivery card etc. are maintained. A card containing the health record of the child is given to the mother.

5. Non-formal pre-school education
Children between the ages 3–6 years are imparted non-formal pre-school education in an anganwadi in each village with about 1000 population. The objective is to provide opportunities to develop desirable attitude, values and behaviour pattern among children. Locally produced inexpensive toys and material are used in organizing play and creative activity.

Schemes for adolescent girls (65)
At present, there are two schemes for adolescent girls viz, “Rishori Shakti Yojana” and “Nutrition Programme for adolescent girls”.

Rishori Shakti Yojana is being implemented using the infrastructure of ICDS. The scheme targets adolescent girls in the age group of 11 to 18 years and addresses their needs of self-development, nutrition and health status, literacy and numerical skills, vocational skills etc.

Nutrition Programme for Adolescent Girls was approved in the year 2009–10, on a pilot project basis. The project is being implemented in 51 identified districts from the major states. Undernourished adolescent girls in the age group of 11 to 19 years (with body weight less than 30 kg in the age group of 11 to 15 years and 35 kg in the age group of 15 to 19 years) are covered under the scheme. 6 kg of free food grain is provided to each beneficiary per month. The programme is being implemented through the administrative set-up of ICDS scheme at the state, district, block and Anganwadi Centre level.

Two more schemes are being implemented at the ICDS level. They are (a) Rajiv Gandhi Scheme for Empowerment of Adolescent Girls – “SABLA” for the age group 11 to 18 years to improve their nutritional and health status; and (b) Indira Gandhi Matru Sewa Sahyog Yojana (IGMSY), under which conditional cash transfer will be made to pregnant and lactating mothers in order to improve their nutritional and health status (65).

At the end of 2012, about 6,906 ICDS projects and 13.04 lakh Anganwadi Centres/Mini-Aanganwadi Centres are functional in the country. About 751.03 lakh children and 167.62 lakh pregnant and lactating mothers (total 918.65 lakh) are getting the benefit of the scheme.

The administrative unit of an ICDS project is the “community development project” in rural areas, the “tribal development block” in tribal areas and a group of slums in urban areas. In selection of project areas preference was given to areas predominantly inhabited by backward tribes, backward areas, drought prone areas and areas in which nutritional deficiencies are rampant. The rural/urban project has a population of 100,000 and a tribal project about 35,000 population. The number of villages in the rural project may be 100 while in tribal areas, it may be only about 50, taking into account the difficult terrain in which the tribal projects are located. The focal point for the delivery of integrated early childhood services under the ICDS scheme is the trained local woman known as Anganwadi worker (AWW). Other functionaries in the ICDS are the Child Development Project Officer (CDPO), who is in charge of 4 Supervisors (Mukhya Sevikas) and 100 AWWs. Each Supervisor is responsible for 20–25 anganwadi and acts as mentor to AWWs; assists in record keeping, visits of health personnel and organizing community visits; and provides on-the-job training to AWWs. Anganwadi worker is the multipurpose agent, selected from the community. AWW provides direct link to children and mother; assists CDPO in survey of community and beneficiaries; organizes non-formal education sessions; provides health and nutrition education to mothers; assists PHC staff in providing health services; maintains records of immunization, feeding and pre-school attendance; liaises with block administrator, local school, health staff and community, and works for other community based activities, e.g., family planning.

The Government of India is committed to child development as a policy priority and is steadily expanding ICDS programme with the ultimate aim of reaching every child. The impact of the programme on the lives of children is evident in several crucial indicators: increased birth
Health of adolescents

The term "adolescence" has been defined as including the age between 10 and 19, and "youth" those between 15 and 24. "Young people" is a term that covers both age groups, i.e. those between the ages of 10 and 24.

True adolescence, however, being the period of physical, psychological and social maturing from childhood to adulthood, may fall within either age range. The development that takes place in adolescence is generally uneven, in that physical maturity may well be achieved in advance of psychological or social maturity; in most societies, in fact, reproductive capability is now established at an earlier age than in the past.

The importance of the health of adolescents has started to receive increasing recognition, particularly in developing countries where four out of five of the world's young people live, and where more than half the population is under the age of 25. These young men and women are, or will become, the parents of the next generation. They must be given every opportunity to develop to their full potential as healthy individuals.

Because adolescents are less vulnerable to disease than the very young and the very old, health problems specific to their age group have been given little prominence until now. Moreover, in societies where girls in particular have traditionally married at an early age, adolescence has been regarded merely as a brief interlude between puberty and marriage. As the average age of marriage has fallen, and with an increasing trend towards late marriage, however, this period has been extended and traditional attitude has begun to change. At the same time, the influence of the family has declined, urbanization and migration have become more common, and young people have been increasingly exposed to the mass media - all factors that contribute to major changes in social and sexual behaviour.

High rate of mortality and morbidity has always been associated with pregnancy and childbirth in pre-industrial and adolescent girls. This problem is now compounded by the dramatic rise in the number of pregnancies, both wanted and unwanted, among adolescents, who are also having more abortions and contracting sexually transmitted diseases more often. There appears also to be an increase in the number of abandoned and abused children born to adolescent mothers. As long as these problems are allowed to persist, much of the energy, creativity and idealism of youth will be lost to society. However, the problems are preventable, and efforts to eliminate them must involve the young people themselves, contributing in ways appropriate to their particular cultures.

Society today demands more of young people than ever before. With the decline of the extended family greater autonomy is expected of them. Especially in the raising of children; increasing urbanization and industrialization means that economic independence is achieved only through education and training. Early parenthood, particularly for girls, may limit or preclude social and educational development and the ability to achieve full status in society and is associated with greater morbidity and mortality. The World Fertility Survey observed an inverse relationship between fertility and the education of women.

Women with no education have, on average, twice as many children as those with seven or more years of schooling. Consequences of this finding are the increased earning power of educated women, their improved status within the family, and the greater control they are able to exercise over their own lives.

A more universal consequence of early and more frequent childbearing is the increase in population size and growth rate. Where girls marry at 15, the age gap between successive generations may be as low as 20 years; this gap may widen to as much as 30 years where the age at marriage is 25. The sexual behaviour and reproductive patterns of young people are highly susceptible to social influences and related to their own sense of psychological well-being.

Although an adolescent girl is likely to give birth and rear her children within the context of an extended family, the risks she and her children run of illness, injury and death are far greater than those for a mature woman in her twenties. The chances of anaemia, developing during pregnancy, and of retarded fetal growth; premature birth and complications during labour are all significantly higher for the adolescent mother, as are the risks of her own death during pregnancy or childbirth.

Formal education of girls generally ends with marriage, and from then on their social status may well depend on fecundity. An adolescent girl who proves to be infertile (or whose husband is infertile) runs the risk of being rejected by both husband and family and thus of losing what little status she has. The second major set of problems of reproductive health in adolescence results from the profound socio-economic changes taking place in most developing countries. The average age of marriage has fallen, there is a trend towards later marriage, and young people are often less directly supervised than was the case in the past - all of which have the effect of increasing the opportunities for sexual encounter. Since the subject of adolescent sexuality remains taboo in most societies, there is widespread ignorance among young people of the risks associated with unprotected sexual activity. Sources of information and contraceptive advice are rarely available or accessible to them. In addition, impulsive sexual behaviour and non-use of contraceptives are sometimes exacerbated by alcohol and drug abuse.

A number of major approaches to reducing problems by modification of the contributing factors will serve to promote good health among the young and thus to improve health and social development of their communities. These approaches include the following:

1. Informing, educating and sensitizing key groups in society to individual health and social development needs.
2. Advocating appropriate policy, legislation and programmes for promoting adolescent reproductive health.
3. Using appropriate and innovative research to improve knowledge of, and disseminate information about, the factors that influence and determine young people's sexual, contraceptive and reproductive decisions and behaviour.
4. Modifying, extending and evaluating services specially designed to meet young people's needs.
5. Mobilizing the energy, creativity and idealism of young people in promoting health and developing appropriate activities in their communities.

6. Facilitating action to extend education opportunities for girls.

PREVENTIVE MEDICINE AND GERIATRICS

Aging is a natural process. In the words of Seneca; "Old age is an incurable disease", but more recently, Sir James Sterling Row commented: "You do not heal old age. You protect it; you control it; you extend it" (129). These are in fact the basic principles of preventive medicine. Old age should be regarded as a normal, inevitable biological phenomenon. The study of the physical and psychological changes which are incident to old age is called gerontology. The care of the aged is called clinical gerontology or geriatrics. Another aspect of gerontology is social gerontology which was born on the one hand out of the instincts of humanitarian and social attitudes and on the other out of the problems set by the increasing number of old people (130). Experimental gerontology is concerned with research into the basic biological problems of aging, into its physiology, biochemistry, pathology and psychology. The fields of studies range from studies of populations through individuals, organs, systems, tissues and cells, down to the molecular level. GERIATRIC GYNAECOLOGY: With the lengthening span of life a new chapter in gynaecology — geriatric gynaecology — is fast opening up. More patients are coming for repair of prolapse of varying degrees, non-specific vaginitis, ovarian tumours, psychic aberrations and sexual problems. There is ample scope for research into the degenerative and other diseases of old age; their treatment in hospital and general practice; and finally into preventive geriatrics and the epidemiology of conditions affecting the aged.

Size of the problem

Discoveries in medical science and improved social conditions during past few decades have increased the life span of man. The expectation of life at birth in developed countries is over 70 years. The age structure of the population in the developed countries has so evolved that the numbers of old people is continually on the increase. These trends are appearing in all countries where medical and social services are well developed and the standard of living is high.

In the year 2002, there were an estimated 605 million old persons in the world, of which 400 million were living in low-income countries (131). Italy and Japan have the highest proportion of older persons (about 16.7 per cent and 16 per cent respectively in the year 2003). By 2025, the number of elderly people is expected to rise more than 1.2 billion with about 840 million of these in low-income countries (131). In India, although the percentage of aged persons to the total population is low in comparison to the developed countries, nevertheless, the absolute size of aged population is considerable. For the year 2010 the estimates are 8 per cent of total population were above the age of 60 years, and is likely to rise to 19% by 2050. This profound shift in the age of older Indians, brings with it a variety of social, economic and healthcare policy challenges (132).

Health problems of the aged

(1) PROBLEMS DUE TO THE AGEING PROCESS

No one knows when old age begins. The "biological age" of a person is not identical with his "chronological age". It is said that nobody grows old merely by living a certain number of years. Years wrinkle the skin, but worry, doubt, fear, anxiety and self-distrust wrinkle the soul. While aging merely stands for growing old, senescence is an expression used for the deterioration in the vitality or the lowering of the biological efficiency that accompanies aging. With the passage of time, certain changes take place in the organism. These changes are, for the most part deleterious and eventually lead to the death of the organism. Our knowledge about the ageing process is incomplete. We do not know much about the disabilities incident to the ageing process. However the following are some of the disabilities considered as incident to it: (a) senile catact, (b) glaucoma, (c) nerve deafness, (d) osteoporosis affecting mobility (e) emphysema, (f) failure of special senses, (g) changes in mental outlook. This list is not exhaustive; we need to know a lot more about the disabilities incident to the ageing process.

(2) PROBLEMS ASSOCIATED WITH LONG-TERM ILLNESS

Certain chronic diseases are more frequent among the older people than in the younger people. These are: (a) DEGENERATIVE DISEASES OF HEART AND BLOOD VESSELS: Of particular importance after the age of 40, are the degenerative diseases of the heart and blood vessels. The inner walls of arteries break down, and a lipid material is deposited. This in time is replaced by calcium which leads to narrowing of blood vessels or atherosclerosis. This leads to diminished blood supply, thrombus formation, rupture of blood vessels and high blood pressure. No single factor has been identified as the cause of atherosclerosis. Diet, heredity, overweight, nerves and emotional strain have all been implicated. Cardiovascular diseases are the major causes of death in the developed countries. A reduction of body weight and modification of the habits of life are needed to decrease the strain on heart and blood vessels. By these, it is possible to lead a longer and more useful life, (b) CANCER: The danger of cancer looms large past middle life. In the developed countries, cancer is a leading cause of death. The incidence of cancer rises rapidly after the age of 40. Cancer of the prostate is common after the age of 65. (c) ACCIDENTS: Accidents are a health problem in the elderly. The bones become fragile due to a certain amount of decalcification as a result of which they break easily. Accidents are more common in the home than outside. Fracture neck of femur is a very common geriatric problem. (d) DIABETES: Diabetes is a long-term illness due to faulty carbohydrate metabolism. It is a leading cause of death as the population grows older. About 75 per cent of the diabetics are over 50 years of age. (e) DISEASES OF LOCOMOTOR SYSTEM: A wide range of articular and non-articular disorders affect the aged — fibrositis, myositis, neuritis, gout, rheumatoid arthritis, osteoarthritis, bone disorders, spine, etc. These conditions cause more discomfort and disability than any other chronic disease in the elderly. (f) RESPIRATORY ILLNESSES: In the upper decades of life, respiratory diseases such as chronic bronchitis, asthma, emphysema are of major importance. (g) GENITOURINARY SYSTEM: Enlargement of the prostate, dysuria, nocturia, frequent and urgency of micturition are the common complaints.

(3) PSYCHOLOGICAL PROBLEMS

(1) MENTAL CHANGES: Impaired memory, rigidity of
outlook and dislike of change are some of the mental changes in the aged. Reduced income leads to a fall in the living standards of the elderly; it does have mental and social consequences. (2) SEXUAL ADJUSTMENT: Between 40 and 50, there is cessation of reproduction by women and diminution of sexual activity on the part of men. During this phase, physical and emotional disturbances may occur. Irritability, jealousy and dependencyness are very frequent. (3) EMOTIONAL DISORDERS: Emotional disorders result from social maladjustment. The degree of adaptation to the fact of ageing is crucial to a man’s happiness in this phase of life. Failure to adapt can result in bitterness, inner withdrawal, depression, weariness of life, and even suicide.

Lifestyle and healthy ageing
People can do a great deal to influence their individual risk of developing many of the diseases of later life by paying careful attention to lifestyle factors. By adopting a healthier lifestyle, the risk of a whole range of diseases can be reduced. These factors are: (a) DIET AND NUTRITION: A good diet reduces the chances of developing the diseases of old age. As countries rapidly develop economically, diets and lifestyles change considerably and overnutrition replaces undernutrition. One of the problem is excessive fat intake. Saturated fats and trans-fatty acids, have been linked to raised cholesterol levels in the blood, leading to increased risk of cardiovascular diseases. People should eat healthy diet since very early age to avoid or delay diseases. The diet should be balanced with less saturated fats and oils; should contain lots of fruits and vegetables; salt and sugar should be less; include plenty of calcium rich food; eat high fibre diet; (b) EXERCISE: Exercise helps maintain good health, as it helps to control weight, improves emotional well-being and relieves stress, improves blood circulation, increases flexibility, lowers blood pressure, increases energy levels, improves balance and thus reduces the dangers of falls, lowers blood sugar levels thus helps in diabetes, improves bone density and thus helps prevent osteoporosis. (c) WEIGHT: Overweight and obesity have become major problem worldwide and it contributes to many diseases of later life. Obesity is an important factor in heart disease, stroke, hypertension, diabetes, arthritis (especially in the knees), and breast cancer. (d) SMOKING: It is estimated that 22 per cent of men and 18 per cent of women aged 65 to 74 years in developed countries are smokers (131). Though this figure is lower than among younger adults, older people have usually smoked for longer, have been and continue to be heavy smokers, and are likely to have chronic diseases, with smoking causing further deterioration. Former smokers live longer than continuing smokers; smoking cessation at the age of 50 years reduces the risk of dying within the next 15 years by 50 per cent. For some, but not for all former smokers, the risk of developing smoking-related diseases reverts to that of lifelong non-smokers (131). (e) ALCOHOL: Drinking beyond a specified amount contributes to a number of later life diseases. Research suggests that sensitivity to the effect of alcohol increases with age. Older people achieve a higher blood alcohol concentration, than younger people after consuming an equal amount of alcohol. This is largely as a result of the age-related decrease in the amount of body water which dilutes alcohol. While younger people are likely to develop tolerance to increasing amount of alcohol, older people have a decreased ability to develop this tolerance (131). Drinking is linked to liver diseases, stomach ulcers, gout, depression, osteoporosis, heart disease, breast cancer, diabetes and hypertension (132). (f) SOCIAL ACTIVITIES: People who become socially isolated — who rarely go out, do not join in the community activities, have few friends or do not see much of their family — are less healthy. Getting out and keeping involved with others creates a sense of belonging. Mixing with other people of similar age, at similar stage of life or perhaps with similar health concerns, can help people realize that they are not alone. The support gained from others can be important in recovering from illness. Simply knowing that others care, helps (132).

Health status of the aged in India
A few hospital based studies have been made in India on the health status of the aged persons, but such studies provide only a partial view of the spectrum of illness in the aged. The overall data on aged are scarce. The main causes of illness are arthritis, cataract, bronchitis, asthma, ear diseases, hypertension, diabetes, rheumatism, helminthic infestations, accidents, etc. The findings of an ICMR survey conducted in 1984-85 of elderly persons over 60 years of age attending geriatric clinics in rural areas is as shown in Table 31.

Source: (132)

The government of India announced a National Policy on older persons in January 1999. This policy identifies principal areas of intervention as financial security, health care, nutrition, shelter, education, welfare, protection of life and property of older citizens. The policy provides for a broad framework for collaboration and cooperation, both within as well as between governmental and non-governmental agencies. An important thrust in the policy is an active and productive involvement of older persons, and not just their care. A national council for older persons (NCOP) was constituted to operationalise the policy. An integrated programme for older persons has been formulated by revising the earlier scheme of assistance to voluntary organizations for programmes relating to the welfare of the aged. The objective is to promote a society for all ages, to empower and improve the quality of life of older persons. The programme for the first time recognizes formation of self-help groups, association of older people for advancement of their rights and utilization of their
experience and services. 234 Old age homes, 398 day care centres and 40 mobile medical units are operational. Scheme of assistance to Panchayat Raj Institutions / Voluntary Organizations / Self Help Groups, for construction of old age homes has also been revised to encourage Multi Service Centres for older persons.

As a part of National Social Assistance Programme, old age pension is being provided to more than 4 million destitute elderly all over the country. The amount of pension varies from state to state — from Rs 75 per month in Assam to Rs 300 per month in West Bengal and Rajasthan (131). An Old Age Social and Income Security (OASIS) project was launched to comprehensively examine policy questions, connected with Old Age Income Security. Travel related concessions / facilities are provided to the older persons by Indian Railways, Indian Airlines and State Transport Corporations. Health care is being provided to the older persons through Bhavishya Arogya Medilcaim, and Rural Group Life Insurance Schemes. Income Tax Concessions are also available to the elderly citizens.

On 19th Nov. 2007, the Indira Gandhi National Old Age Pension Scheme was launched to provide monthly pension to people over 65 years and living below poverty line. The scheme is to cover about 1.57 crore people, the central government is to provide a monthly pension of Rs. 200 to each beneficiary and the state governments are expected to contribute an equal amount.

In India, HelpAge India is the largest voluntary organization working for the cause and care of the disadvantaged older people. In the 26 years since its inception, it has made an impact on the lives of nearly 6 million senior citizens, through 3,084 projects. HelpAge India supports the following programmes to make life easier for older people: (a) Free cataract operations; (b) Mobile medical units; (c) Income generation and micro-credit; (d) Old-age homes and day-care centres; (e) Adopt-a-Gran (grandparent); and (f) Disaster mitigation.

**Implication of the ageing population in terms of preventive and social medicine**

The ageing population is both a medical and sociological problem. It makes a greater demand on the health services of a community. In rapidly greying world, healthy ageing is vital for countries. It is a prerequisite for economic growth. The predicted explosion of non-communicable diseases like cardiovascular diseases, cancer, and depression in the ever increasing number of older persons globally, will result in enormous human and social costs unless preventive action is taken.

The alteration of the age pyramid, however, poses significant new challenges for governments, societies, and families in the 21st century. Ageing developing countries are slated to face a heavy double burden of infectious and non-communicable diseases, yet they often lack significant resources, including comprehensive ageing policies, to cope. Industrialized countries, on the other hand, are fortunate enough to become affluent before they became old (131).

The modern philosophy is that the old must continue to take their share in the responsibilities and in the enjoyment of the privileges, which are an essential feature of remaining an active member of the community. The community must assist the aged to fight the triple evils of poverty, loneliness and ill-health.

**Potential for disease prevention in the elderly**

For older individuals, a great proportion of the disease burden derives from existing conditions, whether this burden is measured by prevalence rates, indicators of morbidity, disability, mortality, or by health and long term care utilisation. In addition, older people with disability, resulting from chronic diseases, appear at high risk of acute illness and injuries. The evidence arrayed of the role of existing and often immutable disease argues for the importance of secondary and tertiary prevention, in combination with primary screening or prevention for this population (134).

Among older individuals, categories of conditions, occurrences, and illnesses exist in a variety of combinations, and risk factors as well as disease sequelae often overlap. Examples of conditions potentially amenable to prevention in older persons are outlined in Table 32.

Many factors that contribute to decrements of ageing and the burden of illness are potentially responsive to preventive interventions. In view of this evidence, the design of preventive strategies appropriate to this population becomes crucial for the utility of preventive care, both in reducing risk and maintaining functional independence.

Much care is bestowed upon the old people in Western societies by providing Social Welfare measures such as national assistance, supplementary pensions, home services, home care services, meals on wheels services, old folk’s homes, sitters-up service and provision of services of health visitors. By providing these services, the State ensures that the years of retirement of those who have worked hard in its service shall be free from anxiety, want and boredom.

### Table 32

| Areas potentially amenable to preventive health care in the elderly |
|-------------------|-----------------|----------------|
| **Primary**       | **Secondary**   | **Tertiary**   |
| Health habits     | Screening for   | Rehabilitation |
| - smoking         | - hypertention  | - physical deficits |
| - alcohol abuse   | - diabetes      | - cognitive deficits |
| - obesity         | - pointed disease | - functional deficits |
| - nutrition       | - dental carier |                   |
| - physical activity | - sensory impairment |                  |
| - sleep           | - medication side-effect | Carer support |
| Coronary heart disease risk factors | - anginoisat | Introduction to necessary to prevent loss of autonomy |
| - breast cancer   | - cervical cancer | - postastic cancer |
| - infection       | - alimentary-induced | - anemia |
| - depression      | - diabetes, stress | - osteoarthritis |
| - retention       | - physical intolerance | - stroke and heart failure |
| Injury prevention | - fall risk      | - osteoporosis prevention |
| Liver cancer      | - hepatitis | - high-risk |
| Prevention        | - renal failure | - stroke prevention |
| Osteoporosis      | - high-risk | - myocardial infarction |

ANNEXURE A (135)

ASSESS AND CLASSIFY THE SICK YOUNG INFANT

AGE UPTO 2 MONTHS

The steps to assess and classify a sick young infant during an initial visit are:

- Check for signs of possible bacterial infection. Then classify the young infant based on the clinical signs found.
- Ask about diarrhoea. If the infant has diarrhoea, assess for related signs. Classify the young infant for dehydration. Also classify for persistent diarrhoea and dysentery if present.
- Check for feeding problem or low weight. This may include assessing breast-feeding. Then classify feeding.
- Check the young infant's immunization status.
- Assess any other problems.

If you find a reason that a young infant needs urgent referral, you should continue the assessment.

CHECK FOR POSSIBLE BACTERIAL INFECTION / JAUNDICE

ASK:

- Has the infant had convulsions?

LOOK, LISTEN, FEEL:

- Count the breaths in one minute. Repeat the count if elevated.
- Look for severe chest indrawing.
- Look for nasal flaring.
- Look and listen for grunting.
- Look and feel for bulging fontanelle.
- Look for pus draining from the ear.
- Look at the umbilicus. Is it red or draining pus?
- Look for skin pustules. Are there 10 or more skin pustules or a big boil?
- Measure axillary temperature (if not possible, feel for fever or low body temperature).
- See if the young infant is lethargic or unconscious.
- Look at the young infant's movements. Are they less than normal?
- Look for jaundice. Are the palms and soles yellow?

YOUNG INFANT MUST BE CALM

CLASSIFY ALL YOUNG INFANTS

CLASSIFY AS

Severe Jaundice

Jaundice

LOCAL BACTERIAL INFECTION

POSSIBLE SERIOUS BACTERIAL INFECTION

CONJUNCTIVITIS

Fast breathing (60 breaths per minute or more), or
Severe chest indrawing, or
Nasal flaring, or
Grunting, or
Rumbling fontanelle, or
10 or more skin pustules or a big boil, or
If axillary temperature 37.5°C or above (or feels hot to touch) or temperature less than 35.5°C (or feels cold to touch), or
Lethargic or unconscious, or
Less than normal movements.

Give first dose of intramuscular ampicillin and gentamicin.

Give and warm in a mosque or amougyziki for 5 days.

Give and warm in a mosque or amougyziki for 5 days.

Give and warm in a mosque or amougyziki for 5 days.

Give and warm in a mosque or amougyziki for 5 days.

Advisement mother to breast-feed.

Advisement mother to breast-feed.

Advisement mother to breast-feed.

**Preventive Medicine in Obstetrics, Paediatrics and Geriatrics**

**TREATMENT**  
(Urgent pre-referral treatments are in bold type.)

<table>
<thead>
<tr>
<th>TWO OF THE FOLLOWING SIGNS:</th>
<th>CLASSIFICATION</th>
<th>TREATMENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lethargic or unconscious.</td>
<td>SEVERE DEHYDRATION</td>
<td>Give first dose of intramuscular ampicillin and gentamicin.</td>
</tr>
<tr>
<td>Sunken eyes.</td>
<td></td>
<td>If infant also has low weight or another severe classification. - Refer urgently to hospital with mother giving frequent sips of ORS on the way. - Advise mother to continue breast-feeding. - Advise mother how to keep the young infant warm on the way to the hospital. OR If infant does not have low weight or any other severe classification. Give fluid for severe dehydration (Plan C) and then refer to hospital after rehydration.</td>
</tr>
<tr>
<td>Skin pinch goes back very slowly.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**CLASSEFYING**

**CLASSIFICATION**

- SEVERE DEHYDRATION
- SOME DEHYDRATION
- NO DEHYDRATION

**SIGNS**

- Lethargic or unconscious.
- Sunken eyes.
- Skin pinch goes back very slowly.

**TREATMENT**

- Given first dose of intramuscular ampicillin and gentamicin.
- If infant also has low weight or another severe classification:
  - Refer urgently to hospital with mother giving frequent sips of ORS on the way.
  - Advise mother to continue breast-feeding.
  - Advise mother how to keep the young infant warm on the way to the hospital.
- If infant does not have low weight or any other severe classification:
  - Give fluids for some dehydration (Plan B).
  - Advise mother when to return immediately.
  - Follow-up in 12 days.

**IF YES ASK:** LOOK AND FEEL:

- For how long?
- Look at the young infant's general condition. Is the infant:
  - Lethargic or unconscious?
  - Sunken eyes?
  - Skin pinch goes back very slowly?
- Look for sunken eyes.
- Pinch the skin of the abdomen. Does it go back: Very slowly (longer than 2 seconds)? Slowly?

**CLASSIFICATION**

- SEVERE DEHYDRATION
- SOME DEHYDRATION
- NO DEHYDRATION

**If diarrhoea has lasted for 14 days or more:**

**TREATMENT**

- Give first dose of intramuscular ampicillin and gentamicin if the young infant has low weight, dehydration or another severe classification.
- Advise how to keep infant warm on the way to the hospital.
- Refer to hospital.

**If blood in stool:**

**TREATMENT**

- Given first dose of intramuscular ampicillin and gentamicin if the young infant has low weight, dehydration or another severe classification.
- Treat to prevent low blood sugar.
- Advise how to keep infant warm on the way to the hospital.
- Refer to hospital.
THEN CHECK FOR FEEDING PROBLEM & MALNUTRITION:

ASK:
1. Is there any difficulty in feeding?
2. Is the infant breastfed? If yes, how many times in 24 hours?
3. Does the infant usually receive any other food or drinks? If yes, how often?
4. What do you use to feed the infant?

LOOK, FEEL:
1. Determines weight for age.

Classify FEEDING:

<table>
<thead>
<tr>
<th>SIGNS</th>
<th>CLASSIFY AS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not able to feed or</td>
<td>Not able to feed:</td>
</tr>
<tr>
<td>No attachement at all or</td>
<td>Possible Serious</td>
</tr>
<tr>
<td>Not suckling</td>
<td>Bacterial Infection</td>
</tr>
<tr>
<td>Very low weight for age</td>
<td>or Severe Malnutrition</td>
</tr>
</tbody>
</table>

ASSESS BREAST-FEEDING:

1. Has the infant breastfed in the previous hour?
2. Is the infant well attached?
3. If the infant has not fed in the previous hour, ask the mother to put her infant to the breast. Observe the breastfeeding for 5 minutes.
4. Is the infant able to attach?
5. If not, good attachment will not be present if the attachment is good.

TO CHECK ATTACHMENT, LOOK FOR:
- Chin touching breast
- Mouth wide open
- Lower lip turned outward
- More accessible above than below the mouth.

 Does the mother have pain while breastfeeding? Engorged breasts or breast abscess.

CATEGORIZE:

<table>
<thead>
<tr>
<th>FEEDING PROBLEM OR LOW WEIGHT</th>
</tr>
</thead>
<tbody>
<tr>
<td>If not well attached or not suckling effectively, teach correct positioning and attachment.</td>
</tr>
<tr>
<td>If breastfeeds less than 8 times in 24 hours, advise to increase frequency of feeding.</td>
</tr>
<tr>
<td>If receiving other foods or drinks, counsel mother about breastfeeding more, reducing other foods or drinks, and using a cup and spoon.</td>
</tr>
<tr>
<td>If not breastfeeding at all, advise mother about giving breast-appropriate animal milk and teach the mother how to feed with a cup and spoon.</td>
</tr>
<tr>
<td>If breastfeeds at home, teach the mother how to keep the young infant with low weight warm at home.</td>
</tr>
<tr>
<td>If breast or nipple problem, teach the mother to breast or nipple problems.</td>
</tr>
<tr>
<td>If not breastfeeding at home, advise mother to give home care for the young infant.</td>
</tr>
<tr>
<td>If low weight for age, teach the mother how to breastfeed immediately.</td>
</tr>
<tr>
<td>Follow-up for feeding problem or thrust in 2 days.</td>
</tr>
</tbody>
</table>

NO FEEDING PROBLEM:

<table>
<thead>
<tr>
<th>NO FEEDING PROBLEM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Advise mother to give home care for the young infant.</td>
</tr>
<tr>
<td>Advise mother when to return immediately.</td>
</tr>
<tr>
<td>Praise the mother for feeding the infant well.</td>
</tr>
</tbody>
</table>

TREATMENT:
( Urgent pre-referral treatment in bold print.)

Give first dose of Intramuscular ampicillin and gentamicin.

To treat low birth weight.

Warm the young infant by skin to skin contact if temperature less than 36.5°C (or feels cold to touch) while arranging referral.

Advise mother how to keep the young infant warm on the way to the hospital.

Refer to hospital.
# Assess and Classify the Sick Child

**Age 2 Months up to 5 Years**

**Ask the Mother What the Child's Problems Are**
- Determine if this is an initial or follow-up visit for this problem.
  - If follow-up visit, use the follow-up instructions on TREAT THE CHILD.
  - If initial visit, assess the child as follows:

**Check for General Danger Signs**

<table>
<thead>
<tr>
<th>ASK</th>
<th>LOOK</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the child able to drink or breathe?</td>
<td>See if the child is lethargic or unconscious.</td>
</tr>
<tr>
<td>Does the child vomit everything?</td>
<td></td>
</tr>
<tr>
<td>Has the child had convulsions?</td>
<td></td>
</tr>
</tbody>
</table>

A child with any general danger sign needs urgent attention; complete the assessment and any pre-referral treatment immediately so referrals not delayed.

**Use All Boxes That Match the Child's Symptoms and Problems to Classify the Illness.**

**Then Ask About Main Symptoms:**
Does the child have cough or difficult breathing?

### If Yes Ask

<table>
<thead>
<tr>
<th>Look, Listen</th>
<th>Classify Cough or Difficult Breathing</th>
<th>Sign</th>
<th>Classify As</th>
<th>Identify Treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>If the child is:</td>

<td>Any general danger sign or:</td>
<td>PNEUMONIA</td>
<td>Give first dose of injectable chloramphenicol (if not possible give oral amoxicillin).</td>
</tr>
<tr>
<td>2 months up to 12 months</td>
<td>2 months up to 12 months</td>
<td>Chest indrawing or</td>
<td>SEVERE PNEUMONIA OR VERY SEVERE DISEASE</td>
<td>Refer URGENTLY to hospital.</td>
</tr>
<tr>
<td>12 months up to 5 years</td>
<td>12 months up to 5 years</td>
<td>Stridor in calm child</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Fast breathing.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2 months up to 12 months</td>
<td>No signs of pneumonia or very severe disease.</td>
<td>NO PNEUMONIA; COUGH ON COLD</td>
<td></td>
</tr>
<tr>
<td></td>
<td>12 months up to 5 years</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>20 breaths per minute or more</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>40 breaths per minute or more</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Clarinex for 5 days.**
- Soothe the throat and relieve the cough with a safe remedy if child is 6 months or older.
- Advise mother when to return immediately.
- Follow-up in 2 days.

**If coughing more than 30 days, refer for assessment.**
- Soothe the throat and relieve the cough with a safe home remedy if child is 6 months or older.
- Advise mother when to return immediately.
- Follow-up in 5 days if not improving.
### Does the child have diarrhoea?

**IF YES ASK:**
- Fever high?
- Is three blood in stool?

**LOOK AND FEEL:**
- Look at the child’s general condition.
- Is the child:
  - Lethargic or unconscious?
  - Restless and irritable?
  - Look for sunken eyes?
  - Offer the child fluid.
- Is the child:
  - Not able to drink or drinking poorly?
  - Drinking eagerly, thirsty?
  - Pusy the skin of nasopharynx.
  - Does it go back:
    - Very slowly (longer than 2 seconds)?
    - Slowly?

#### SIGNS CLASSIFY AS

<table>

<tr>
<td>Follow-up in 5 days if not improving</td>
<td></td>
</tr>
</tbody>
</table>

#### TREATMENT

- Dehydration present: SEVERE PERSISTENT DEHYDRATION
- Treat dehydration before referral unless the child has another severe classification
- Refer to hospital

- No Dehydration: PERSISTENT DEHYDRATION
- Advise the mother on feeding child who has persistent diarrhoea
- Give single dose of vitamin A
- Give zinc sulphate 20 mg daily for 3 days
- Follow-up in 5 days

- Blood in stool: DIARRHOEA
- Treat for 5 days with cotrimoxazole
- Follow-up in 2 days
Does the child have fever?
(by history or feels hot or temperature 37.5°C or above)

IF YES:
• Decide Malaria Risk:
  High/Low

THEN ASK:
• Fever for how long?
  If more than 7 days, has fever been present every day?
  • Has the child had measles within the last 3 months?
If the child has measles now or within the last 3 months:

**LOOK AND FEEL:**
• Look for signs of Measles: Generalized rash and One of these: cough, runny nose, or red eyes.
• Look for mouth ulcers. Are they deep and extensive?
• Look for pus draining from the eye.
• Look for clouding of the cornea.

IF MEASLES:
• Nasal or within last 3 months. Classify

* This cut-off is for auxiliary temperature, rectal temperature cut-off is approximately 0.5°C higher.
** Other causes of fever include cough or cold, pneumonia, diarrhea, dysentery and skin infections.

OTHER IMPORTANT COMPLICATIONS OF MEASLES - PNEUMONIA, ENDOXIA, DIARRHEA, EAR INFECTION, AND MALNUTRITION - ARE CLASSIFIED IN OTHER TABLES.

SIGN CLASSIFY AS TREATMENT

| HIGH MALARIA RISK | VERY SEVERE FEBRILE DISEASE | GIVE first dose of IM quinine after making a blood smear.
|                  |                             | Give first dose of IV or IM chloroquine (if not possible, give oral amoxicillin).
|                  |                             | Treat the child to prevent low blood sugar.
|                  |                             | Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).
|                  |                             | Refer URGENTLY to hospital.

| LOW MALARIA RISK | VERY SEVERE FEBRILE DISEASE | GIVE first dose of IM quinine after making a blood smear.
|                  |                             | Give first dose of IV or IM chloroquine (if not possible, give oral amoxicillin).
|                  |                             | Treat the child to prevent low blood sugar.
|                  |                             | Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).
|                  |                             | Refer mother when to return immediately.
|                  |                             | Follow-up in 2 days if fever persists.

| MALARIA | GIVE oral antimalarials for HIGH MALARIA risk area after making a blood smear.
|         | Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).
|         | Refer mother when to return immediately.
|         | Follow-up in 2 days if fever persists.

| MALAPRA | GIVE one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).
|         | Refer mother when to return immediately.
|         | Follow-up in 2 days if fever persists.

| FEVER MALARIAl UNLIKELY | Give one dose of paracetamol in clinic for high fever (temp. 38.5°C or above).
|                          | Refer mother when to return immediately.
|                          | Follow-up in 2 days if fever persists.

| SEVERE COMPLICATED MEASLES* | GIVE first dose of Vitamin A.
|                             | Give first dose of injectable chloroquine (if not possible give oral amoxicillin).
|                             | If clouding of the cornea or pus draining from the eye, apply tetracycline eye ointment.
|                             | Refer URGENTLY to hospital.

| MEASLES WITH EYE OR MOUTH COMPLICATIONS | GIVE first dose of Vitamin A.
|                                        | If pus draining from the eye, treat eye infection with tetracycline eye ointment.
|                                        | If mouth ulcer, treat with gentian violet.
|                                        | Follow up in 2 days.

| MEASLES | GIVE first dose of Vitamin A.
|         | Give first dose of vitamin A.

**THEN CHECK FOR MALNUTRITION**

**LOOK AND FEEL:**
- Look for visible severe wasting.
- Look for oedema of both feet.
- Determine weight for age.

**CLASSIFY NUTRITIONAL STATUS**
- Visible severe wasting or severe malnutrition.
- Oedema of both feet.

**SEVERE MALNUTRITION**
- Very low weight for age.
- Net very low weight for age and no other signs of malnutrition.

**TREATMENT**
- Give single dose of Vitamin A.
- Refer URGENTLY to hospital.
- While referral is being organized, warn the child.
- Keep the child warm on the way to hospital.
- Assess and counsel for feeding.
- Advise mother when to return immediately.
- Follow-up in 30 days.
- If child is less than 2 years old, assess the child's feeding and counsel the mother on feeding.
  - If feeding problem, follow-up in 5 days.
  - Advise mother when to return immediately.

**THEN CHECK FOR ANAEMIA**

**LOOK:**
- Look for palmar pallor. Is it:
  - Severe palmar pallor?
  - Some palmar pallor?

**CLASSIFY ANAEMIA**
- Severe palmar pallor
- Some palmar pallor
- No palmar pallor

**SEVERE ANAEMIA**
- Refer URGENTLY to hospital.
- Give iron folic acid therapy for 14 days.
- Assess the child’s feeding and counsel the mother on feeding.
  - If feeding problem, follow-up in 5 days.
  - Advise mother when to return immediately.
  - Follow-up in 14 days.

**THEN CHECK THE CHILD’S IMMUNIZATION.** **PROPHYLACTIC VITAMIN A & IRON-FOLIC ACID SUPPLEMNTATION STATUS**

**PROPHYLACTIC VITAMIN A**
- Give a single dose of vitamin A: 100,000 IU at 9 months with measles immunization.
  - 200,000 IU at 16-18 months with DPT Booster.
  - 200,000 IU at 30 months
  - 200,000 IU at 36 months

**PROPHYLACTIC IFA**
- Give 20 mg elemental iron + 100 mcg folic acid (one tablet of Paediatric IFA or 5 ml of IFA syrup or 1 ml of IFA drops) for a total of 100 days in a year after the child has recovered from acute illness if:
  - The child is 6 months of age or older, and
  - Has not received Paediatric IFA tablet syrup/drops for 100 days in last one year.

*A child who needs to be immunized should be advised to go for immunization the day vaccines are available at AWC/SC/THC.
** Hepatitis B to be given wherever included in the immunization schedule.

**ASSES OTHER PROBLEMS**

**MAKE SURE CHILD WITH ANY GENERAL DANGER SIGN IS REFERRED**
- After first dose of an appropriate antibiotic and other urgent treatment.
- Exception: Reproduction of the child according to Plan C may receive danger signs so that referral is no longer needed.
Treatment in the out-patient health facility of the sick child from age 2 months upto 5 years

NO DEHYDRATION

WHO Treatment Plan A

Plan A focuses on the three rules of home treatment: give extra fluids, continue feeding, and advise the caretaker when to return to the doctor (if the child develops blood in the stools, drinks poorly, becomes sicker, or is not better in three days).

Fluids should be given as soon as diarrhoea starts; the child should take as much as s/he wants. Correct home therapy can prevent dehydration in many cases. ORS may be used at home to prevent dehydration. However, other fluids that are commonly available in the home may be less costly, more convenient and almost as effective. Most fluids that a child normally takes can also be used for home therapy. The following are recommended when ORS is given with ORS.

Recommended home fluid should be:
- Safe when given in large volumes. Very sweet tea, soft drinks, and sweetened fruit drinks should be avoided. These are often hyperosmolar owing to their high sugar content (less than 300 mOsm/L). They can cause osmotic diarrhoea, worsening dehydration and hypoperistalsis. Also to be avoided are fluids with purgative action and stimulants (e.g., coffee, some medicinal tea or infusions).
- Easy to prepare. The recipe should be familiar and its preparation should not require much effort or time. The required ingredients and measuring utensils should be readily available and inexpensive.
- Acceptable. The fluid should be one that the mother is willing to give freely to a child with diarrhoea and that the child will readily accept.
- Effective. Fluids that are safe are also effective. Most effective are fluids that contain carbohydrates and protein and some salt. However, nearly the same result is obtained when fluids are given freely along with weaning foods that contain salt.

SOME DEHYDRATION

WHO Treatment Plan B

Give initial treatment with ORS over a period of four hours. The approximate amount of ORS required (in ml) can be calculated by multiplying the child's weight (in kg) times 75; during these four hours, the mother slowly gives the recommended amount of ORS by spoonfuls or sips.

Note: If the child is breastfed, breast-feeding should continue. After four hours, the child is re-assessed and re-classified for dehydration, and feeding should begin; resuming feeding early is important to provide required amounts of potassium and glucose. When there are no signs of dehydration, the child is put on Plan A. If there is still some dehydration, Plan B should be repeated. If the child now has severe dehydration, the child should be put on Plan C.

SEVERE DEHYDRATION

Plan C – Treat Severe Dehydration Quickly

If you can give intravenous (IV) treatment and you have acceptable solutions such as Ringer's Lactate or Normal Saline at the clinic, give the solution intravenously to the severely dehydrated child.

The sections of Plan C below describe the steps to rehydrate a severely dehydrated child. It includes the amounts of IV fluid that should be given according to the age and weight of the child:

- Start IV fluid immediately. If the child can drink, give ORS by mouth while the drip is set up. Give 100 ml/kg Ringer's Lactate Solution (or, if not available, normal saline), divided as follows:

<table>
<thead>
<tr>
<th>Age</th>
<th>First dose (30 ml/kg)</th>
<th>Then give 70 ml/kg in:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infants (under 12 months)</td>
<td>1 hour *</td>
<td>5 hours</td>
</tr>
<tr>
<td>Children (12 months to 5 years)</td>
<td>0.5 hour *</td>
<td>2 hours</td>
</tr>
</tbody>
</table>

* Repeat once if radial pulse is still very weak or not detectable.

- Re-assess the child every 1–2 hours. If hydration status is not improving, give the IV drip more rapidly.
- Also give ORS (about 3 ml/kg/hour) as soon as the child can drink: 0.5 hourly after 3–4 hours (infants) or 1–2 hours (children).
- Re-assess an infant after 6 hours and a child after 3 hours. Classify dehydration. Then choose the appropriate plan (A, B or C) to continue treatment.

Note:
- If possible, observe the child at least 6 hours after rehydration to be sure the mother can maintain hydration giving the child ORS solution by mouth.

Nutrition may be defined as the science of food and its relationship to health. It is concerned primarily with the part played by nutrients in body growth, development and maintenance (1). The word Nutrient or “food factor” is used for specific dietary constituents such as proteins, vitamins and minerals. Dietetics is the practical application of the principles of nutrition; it includes the planning of meals for the well and the sick. Good nutrition means “maintaining a nutritional status that enables us to grow well and enjoy good health” (2). The subject of nutrition is very extensive. Since our concern is with community aspects of nutrition, the subject will be dealt with in five sections: dietary constituents, nutritional requirements, assessment of nutritional status, nutritional problems in public health and nutritional programmes in India.

Changing concepts

Through centuries, food has been recognized as important for human beings, in health and disease. The history of man to a large extent has been a struggle to obtain food. Until the turn of the nineteenth century the science of nutrition had a limited range. Protein, carbohydrate and fat had been recognized early in the 19th century as energy-yielding foods and much attention was paid to their metabolism and contribution to energy requirements (3). The discovery of vitamins “rediscovered” the science of nutrition. Between the two World Wars, research on protein gained momentum. By about 1950, all the presently known vitamins and essential amino acids had been discovered. Nutrition gained recognition as a scientific discipline, with roots in physiology and biochemistry. In fact, nutrition was regarded as a branch of physiology and taught as such to medical students.

Great advances have been made during the past 50 years in knowledge of nutrition and in the practical application of that knowledge. Specific nutritional diseases were identified and technologies developed to control them, as for example, protein-energy malnutrition, endemic goitre, nutritional anaemia, nutritional blindness and diarrhoeal diseases.

While attention was concentrated on nutritional deficiency diseases during the first decades of the century, the science of nutrition was extending its influence into other fields: agriculture, animal husbandry, economics and sociology. This led to “green revolution” and “white revolution” in India and increased food production. However, studies of the diets and state of nutrition of people in India showed that poorer sections of the population continued to suffer from malnutrition despite increased food production. One result was that for the first time the problem of nutrition began to attract international attention as a cause of social problems. International activities in the field of nutrition initiated by the League of Nations, later continued by FAO, WHO and UNICEF form a striking part of the story.

Significant advances have been made during the past two decades. The association of nutrition with infection, immunity, fertility, materials and child health and family health have engaged scientific attention. More recently, a great deal of interest has been focused on the role of dietary factors in the pathogenesis of non-communicable diseases such as coronary heart disease, diabetes and cancer.

It has been said that most nutrition scientists are far more familiar with rats than with humans. Of greater significance during recent years is that the science of nutrition has moved out of the laboratory and linked itself to epidemiology. This association has given birth to newer concepts in nutrition such as epidemiological assessment of nutritional status of communities, nutritional and dietary surveys, nutritional surveillance, nutritional and growth monitoring, nutritional rehabilitation, nutritional indicators and nutritional interventions – all parts of what is broadly known as nutritional epidemiology. Epidemiological methods are now increasingly used not only in the elucidation of disease aetiology and identification of risk factors of disease, but also in the planning and evaluation of nutritional programmes. With these newer concepts and newer approaches, nutritional science has become more dynamic.

Another concept that has emerged in recent years is that nutrition is the cornerstone of socio-economic development, and that nutritional problems are not just medical problems but are “multifactorial” with roots in many other sectors of development such as education, demography, agriculture and rural development. It has become apparent that lasting improvement in the health and nutritional status of people can be brought about only through a successful attack on the basic problems of poverty and injustice. The old concept that the health sector alone is responsible for all nutritional ills of the community has faded away. It is now realized that a broad intersectoral and integrated approach of sectors of development is needed to tackle today’s nutritional problems.

In the global campaign of Health for All, promotion of proper nutrition is one of the eight elements of primary health care (4). Nutritional indicators (5) have been developed to monitor “Health for All”. Greater emphasis is now placed on integrating nutrition into primary health care systems wherever possible, and formulation of national dietary goals to promote health and nutritional status of families and communities.
CLASSIFICATION OF FOODS

There are many ways of classifying foods

1. Classification by origin
   1) Foods of animal origin
   2) Foods of vegetable origin.

2. Classification by chemical composition
   1) Proteins
   2) Fats
   3) Carbohydrates
   4) Vitamins
   5) Minerals.

3. Classification by predominant function
   1) Body-building foods, e.g., milk, meat, poultry, fish, eggs, pulses, groundnuts, etc.
   2) Energy-giving foods, e.g., cereals, sugar, roots and tubers, fats and oils.
   3) Physical foods, e.g., vegetables, fruits, milk.

4. Classification by nutritive value
   1) Cereals and millets
   2) Pulses (legumes)
   3) Vegetables
   4) Nuts and oils
   5) Fruits
   6) Animal foods
   7) Fats and oils
   8) Sugar and jaggery
   9) Condiments and spices
   10) Miscellaneous foods.

NUTRIENTS

Nutrients are organic and inorganic complexes contained in food. There are about 50 different nutrients which are normally supplied through the foods we eat. Each nutrient has specific functions in the body. Most natural foods contain more than one nutrient. These may be divided into:

(i) Macronutrients: These are proteins, fats and carbohydrates which are often called “proteins” because they form the main bulk of food. In the Indian diet, they contribute to the total energy intake in the following proportions:

<table>
<thead>
<tr>
<th>Protein</th>
<th>Carbohydrates</th>
</tr>
</thead>
<tbody>
<tr>
<td>7 to 15 per cent</td>
<td>65 to 80 per cent</td>
</tr>
</tbody>
</table>

(ii) Micronutrients: These are vitamins and minerals. They are called micronutrients because they are required in small amounts which may vary from a fraction of a milligram to several grams. A short review of basic facts about these nutrients is given below.

PROTEINS

The word “protein” by derivation means that which is of first importance. Indeed they are one of the greatest importance in human nutrition. Proteins are complex organic nitrogenous compounds. They are composed of carbon, hydrogen, oxygen, nitrogen and sulphur in varying amounts. Some proteins also contain phosphorus and iron and occasionally other elements. Proteins differ from carbohydrates and fats in that they contain nitrogen, this usually amounts to about 16 per cent. Proteins constitute about 20 per cent of the body weight in an adult.

Essential amino acids

Proteins are made up of smaller units, called amino acids. Some 20 amino acids are stated to be needed by the human body, of which 9 are called “essential” because the body cannot synthesize them in amounts corresponding to its needs, and therefore, they must be obtained from dietary proteins. They are: leucine, isoleucine, lysine, methionine, phenylalanine, threonine, valine, tryptophan and histidine. Evidence is now accumulating that histidine is essential even for adults (6). Non-essential amino acids include arginine, asparagine acid, serine, glutamic acid, proline and glycine. Both essential and non-essential amino acids are needed for synthesis of tissue proteins, the former must be supplied though diet, whereas the latter can be synthesized by the body provided other building blocks are present.

Some of the essential amino acids have important biological functions, such as formation of nicotin from tryptophan; the action of methionine as a donor of methyl groups for the synthesis of choline, folates and nucleic acids. There is evidence that cystine and tyrosine are essential for premature babies (7). New tissues cannot be formed unless all the essential amino acids (EAA) are present in the diet.

A protein is said to be “biologically complete” if it contains all the EAA in amounts corresponding to human needs. When one or more of the EAA are lacking, the protein is said to be “biologically incomplete”. The quality of dietary protein is closely related to its pattern of amino acids. From the nutritional standpoint, animal proteins are rated superior to vegetable proteins because they are “biologically complete”. For example milk and egg proteins have a pattern of amino acids considered most suitable for humans.

FUNCTIONS

Proteins are needed by the body for (a) body building, — this component is most compared with the maintenance component, except in the very young child and infant; (b) repair and maintenance of body tissues; (c) maintenance of osmotic pressure; and (d) synthesis of certain substances like antibodies, plasma proteins, haemoglobin, enzymes, hormones and coagulation factors. Proteins are connected with the immune mechanism of the body. The cells mediated immune response and the bactericidal activity of leukocyte have been found to be lowered in severe forms of protein energy malnutrition. Proteins can also supply energy (4 kcal per gram) when the calorie intake is inadequate, but this is not their primary function. It is considered wasteful if proteins were used for such a purpose.

SOURCES

Humans obtain protein from two main dietary sources; (a) ANIMAL SOURCES: Proteins of animal origin are found in milk, meat, eggs, cheese, fish and fowl. These proteins contain all the essential amino acids (EAA) in adequate amounts. Egg proteins are considered to be the best among food proteins because of their high biological value and digestibility. They are used in nutrition studies as a “reference protein”. (b) VEGETABLE SOURCES: Vegetable proteins are found in pulses (legumes), cereals, beans, nuts, oil-seed cakes, etc. They are poor in EAA. In developing countries such as India, cereals and pulses are the main sources of dietary protein because they are cheap, easily available and consumed in bulk. Protein content of some foods are as given in Table 1.

</tbody>
</table>

Supplementary action of proteins

Man derives protein not from a single source, but from a variety of food sources, animal and vegetable. Cereal proteins are deficient in lysine and threonine; and pulse proteins in methionine. These are known as "limiting" amino acids. When two or more of vegetarian foods are eaten together (as for example, rice-dhal combination in India) their proteins supplement one another and provide a protein comparable to animal protein in respect of EAA. Thus with proper planning, it is possible for a vegetarian to obtain a high grade protein, at low cost, from mixed diets of cereals, pulses and vegetables. This is known as supplementary action of proteins, and is the basis of counselling people to eat mixed diets.

Protein metabolism

There are three features of protein metabolism: (a) since proteins are not stored in the human body in the way that energy is stored in adipose tissue, they have to be replaced every day; (b) the body proteins are constantly being broken down into their constituent amino acids and then reused for protein synthesis. The rates of turnover vary from tissue to tissue. The reutilization of amino acids is a major contributory factor to the economy of protein metabolism (6). The overall rate of turnover in adult man is equivalent to replacement between 1-2 per cent of body protein each day (7); (c) it is not only the amount of protein that is maintained constant, but also the pattern of specific protein in body. For maximum utilization of dietary proteins, the calorie intake should be adequate.

Evaluation of proteins

A knowledge of the amino acid content of protein is not sufficient for the evaluation of protein quality. Information is also required about the digestibility and suitability to meet the protein needs of the body. The parameters used for such an evaluation include the estimation of the biological value, digestibility coefficient, protein efficiency ratio and net protein utilization (8). The net protein utilization (NPU) is considered of more practical value because it is the product of biological value and digestibility coefficient divided by 100. In exact terms, it is the "proportion of ingested protein that is retained in the body under specified conditions for the maintenance and/or growth of the tissues". In other words, growth is an important yardstick for ascertaining the essentiality of a nutrient.

Assessment of protein nutrition status

A battery of tests have been suggested to assess the state of protein nutrition. These include: arm muscle circumference and mid-arm circumference, serum albumin and transferrin, total body nitrogen, etc.

At the present time the best measure of the state of protein nutrition is probably serum albumin concentration. It should be more than 3.5 g/dl, a level of 3.0 g/dl is considered mild degree of malnutrition; a level of 3.0 g/dl is severe malnutrition. Serum albumin and transferrin assist the ability of the liver to synthesize proteins.

Protein requirements

It is customary to express protein requirements in terms of body weight. The Indian Council of Medical Research in 2010 (9) recommended 1.0 g protein/kg body weight for an Indian adult, assuming a NPU of 65 for the dietary proteins. Daily allowances recommended by the ICMR for various population groups are as given in Table 27.

FATS

Fats are solid at 20 deg. C; they are called "oils" if they are liquid at that temperature. Fats and oils are concentrated sources of energy. They are classified as:

(a) Simple lipids, e.g., triglycerides
(b) Compound lipids, e.g., phospholipids
(c) Derived lipids, e.g., cholesterol

The human body can synthesize triglycerides and cholesteryl esters. More than 10 per cent of body weight (99 per cent) in the adipose tissue in the form of triglycerides. In normal human subjects, adipose tissue constitutes between 10 to 15 per cent of body weight. The accumulation of one kilogram adipose tissue corresponds to 7,700 kcal of energy (10).

Fatty acids

Fats yield fatty acids and glycerol on hydrolysis. Fatty acids are divided into saturated fatty acids such as lauric, palmitic and stearic acids, and unsaturated fatty acids which are divided into monounsaturated (MUFA) (e.g., oleic acid) and poly-unsaturated fatty acids (PUFA) (e.g., linolenic acid and α-linolenic acid). Table 2 shows the fatty acid content of different fats.

The poly-unsaturated fatty acids are mostly found in vegetable oils, and the saturated fatty acids mainly in animal fats. However, there are exceptions, as for example, coconut and palm oils, although vegetable oils, have an extremely high percentage of saturated fatty acids. On the other hand, fish oils, although they are not vegetable oils, contain poly and mono-unsaturated fatty acids.

Essential fatty acids

Essential fatty acids are those that cannot be synthesized by humans. They can be derived only from food. The most important essential fatty acid (EFA) is linoleic acid, which serves as a basis for the production of other essential fatty acids (e.g., linolenic and arachidonic acids). Not all poly-unsaturated fatty acids are essential fatty acids.

**Source:** (11)

**Sources**

The dietary sources of fats may be classified as:

1. (a) **ANIMAL FATS**. The major sources of animal fats are ghee, butter, milk, cheese, eggs, and fat of meat and fish.
2. (b) **VEGETABLE FATS**. Some plants store fat in their seeds, e.g., groundnut oil, sesame, coconut, etc. They are sources of vegetable oils.
3. (c) **OTHER SOURCES**: Small quantities of fat (invisible fats) are found in most foods, e.g., milk, milk products, and eggs, nuts and vegetables. For example, rice contains 3 per cent of fat, wheat 3 per cent, jowar 4 per cent and bajra 6.5 per cent. We eat very little of these foods as they are not very palatable, but in India, they provide considerable amounts of "invisible" fat. Moreover, the body can convert carbohydate into fat.

**Visible and invisible fats**

"Visible" fats are those that are separated from their natural source, e.g., ghee (butter) from milk, cooking oils from oil-bearing seeds and nuts. It is easy to estimate their intake in the daily diet. "Invisible" fats are those which are not visible to the naked eye. They are present in almost every article of food, e.g., cereals, pulses, nuts, milk, eggs, etc. It is difficult to estimate their intake. In fact, the major contribution to total fat intake is from invisible sources rather than visible sources as cereals and pulses constitute the bulk of Indian diet.

Edible plant foods have a low content of fat and saturated fatty acids but they are good source of mono-unsaturated fatty acids and poly-unsaturated fatty acids. In most cereals, millets, pulses and legumes, fat content ranges between 1.5 to 3 per cent. In cereals, millets and most oil seeds, linoleic acid is the major fatty acid whereas pulses, legumes, green leafy vegetables and some oil seeds (e.g. soyabean, rapeseed/mustard and flaxseed) and fenugreek are good sources of both linoleic acid and alpha-linolenic acid. Animal foods like butter, ghee, whole milk cream, fatty milk and mutton provide cholesterol and high amount of saturated fatty acids, and are natural source of trans-fatty acids. Lean meats have a fairly high content of long chain poly-unsaturated fatty acids (PUFA). Poultry meat contains less fat and cholesterol and have high amount of PUFA including long chain PUFA. Egg has high cholesterol but is good source of linoleic acid, alpha-linolenic acid and docosahexaenoic acid (DHA). Fish has less fat, saturated, fatty acids and cholesterol but are good source of PUFA’s. The total quantity of invisible fat and its fatty acid composition depends on the kind of diet consumed (9).

Vegetable oil used in cooking is the major type of visible fat consumed; vanaspati and ghee are the other sources. India has a wide range of edible vegetable oils (groundnut, rapeseed/mustard, soyabean, sunflower, sesame, safflower, ricebran, cottonseed and linseed). In India, the type of vegetable oil consumed varies from one part of the country to the other. Vanaspati (PHVO) promoted as vegetable ghee is used as a substitute for ghee and is used in preparing commercially tied, processed, ready to eat, packaged, frozen, pre-mixed foods and street foods. In recent years, there is change in choice of cooking oils in the urban population. The daily intake of visible fat in rural India is about the same as reported about 25 years back (9).

**Functions**

Fats have always been equated with calories. They are high energy foods, providing as much as 9 kcal for every gram. By supplying energy, fats prevent proteins from being used for energy. Besides providing energy, fats serve as
vehicles for fat-soluble vitamins. Fats in the body support viscera such as heart, kidney and intestine; and fat beneath the skin is a necessary insulation against cold. Without fat food is limited in palatability.

It is only recently that the "non-calorie" roles of fats have been discovered. For example vegetable fats are rich sources of essential fatty acids which are needed by the body for growth, for structural integrity of the cell membrane and decreased platelet adhesiveness. Diets rich in EFA have been reported to reduce serum cholesterol and low-density lipoproteins (LDL). Polyunsaturated fatty acids are precursors of prostaglandins -- a group of compounds, now recognized as "local hormones"; they play a major role in controlling many of the physiological functions of the body such as vascular haemostasis, kidney function, acid secretion in stomach, gastrointestinal motility, lung physiology and reproduction. Cholesterol is essential as a component of membranes and nervous tissue and is a precursor for the synthesis of steroid hormones and bile acids. Thus fats and oils are useful to the body in several ways.

Hydrogenation

When vegetable oils are hydrogenated under conditions of optimum temperature and pressure in the presence of a catalyst, the liquid oils are converted into semi-solid and solid fat. The resulting hydrogenated fat is known as "vanaspati" or vegetable ghee, which is a popular cooking medium in India.

During the process of hydrogenation, unsaturated fatty acids are converted into saturated acids and the EFA content is drastically reduced. The main advantage of vanaspati is its ghee-like consistency and its keeping quality; even in hot humid climater. Since vanaspati is lacking in fat-soluble vitamins, it is fortified with vitamins A and D by government regulation to the extent of 2500 IU of vitamin A and 175 IU of vitamin D per 100 grams.

Trans-fatty acids

Trans-fatty acids are geometrical isomers of Cis-unsaturated fatty acids that adopt a saturated fatty acid like configuration. Partial hydrogenation, the process by which hydrogen is added to the double bonds in essential fatty acids, has shown that trans-fatty acids render the plasma lipid profile of the individual more atherogenic than saturated fatty acids, by not only elevating LDL cholesterol but also by decreasing HDL cholesterol. Several large cohort studies have shown that intake of trans-fatty acids increases the risk of coronary heart disease (13). It takes years for trans-fatty acids to be flushed from the body. Deep fried fast foods, cake mixes, cereals and energy bars, chips and crackers and whipped toppings, packages cookies and candy, packaged doughnuts, pies and cakes are major sources of trans-fatty acids. It is better to look for "partially hydrogenated oil" on the label of any packaged food.

Refined oils

Refining is usually done by treatment with steam, alkali, etc. Refined and deodorization of raw oils is done mainly to remove the free fatty acids and residual materials which may be present in them. Refining does not bring about any change in the unsaturated fatty acid content of the oil. It only improves the quality and taste of oils. Refined oils are costly.

Fats and disease

(a) OBESITY: A diet, rich in fat, can pose a threat to human health by encouraging obesity. In fat people, adipose tissue may increase up to 30 per cent. (b) PHENOMERA: Deficiency of essential fatty acids in the diet is associated with rough and dry skin, a condition known as phenomera or "old skin". This condition is reported in Kerala, Karnataka and Gujarat (14). It is characterized byorny popular eruptions on the posterior and lateral aspects of hands and on the back and buttocks. Phenomera can be cured rapidly by the administration of linseed or safflower oil which are rich in EFA, along with vitamins of the B-complex group.

(c) CORONARY HEART DISEASE: High fat intake (i.e., dietary fat representing 40 per cent or over of the energy supply and containing a high proportion of saturated fats) has been identified as a major risk factor for CHD (15).

Epidemiological studies indicate that LDL and VLDL fractions are atherogenic. HDL exerts a protective effect against the development of atherosclerosis. There is evidence indicating an inverse relationship between EFA intake and CHD mortality. (d) CANCER: In recent years, there has been some evidence that diets high in fat increase the risk of colon cancer and breast cancer (16). (e) OTHERS: The skin lesions of kwashiorkor and those induced by EFA deficiency are similar. The possible association between the skin lesions of kwashiorkor and EFA deficiency has attracted attention (18).

The WHO/FAO Expert Group on diet, nutrition and prevention of chronic diseases endorse that qualitative composition of fats in the diet has a significant role to play in modifying risk factors of CVD and set the following ranges for population nutrient goals (% of Energy): total fat; 15–30 (at least 20% of energy is consistent with good health); Saturated fatty acids less than 10 per cent; PUFA's 6–10 per cent; n-6 about 5–8 per cent; n-3 about 1–2 per cent; Trans-fatty acids less than 1 per cent; MUFA's by difference, and cholesterol less than 300 mg a day (19).

The FAO/WHO expert consultation on fats and fatty acids in human nutrition held in November 2008 in Geneva, Switzerland, reviewed the scientific evidence on nutrient intake values for total fat and fatty acids for different life stages. It also assessed the risks to adequate growth, development and maintenance of health and provided recommendations for infants, children, adults and for women during pregnancy and lactation. Some of their conclusions and recommendations are as follows:

(a) There is convincing evidence on the following:

Energy balance is critical to maintain healthy body weight and ensure optimal nutrient intakes, regardless of macronutrient distribution of energy as % total fat and % total carbohydrates.

Saturated fatty acids (SFAs)

(1) Replacing SFAs with PUFAs decreases LDL cholesterol concentration and the total/HDL cholesterol ratio. A similar but lesser effect is achieved by replacing SFAs with MUFA's.

(2) Replacing SFAs with carbohydrates decreases both LDL and HDL cholesterol concentration but does not change the total/HDL cholesterol ratio.

(3) Replacing SFAs with trans-fatty acids (TFA's) decreases HDL cholesterol and increases the total/ HDL cholesterol ratio.

(4) Considering the data from epidemiological studies on...
morbidity and mortality due to coronary heart disease (CHD) and controlled clinical trials (using CHD events and death), it was also agreed that replacing SFAs with PUFA's decrease the risk of CHD.

MUFAs (Monounsaturated fatty acids)
(1) Replacing carbohydrates with MUFAs increases HDL cholesterol concentrations.
(2) Replacing SFA with MUFA reduces LDL cholesterol concentration and total/HDL cholesterol ratio.

PUFA's (Polyunsaturated fatty acids)
Linoleic acid (LA) and alpha-linolenic acid (ALA) are indispensable since they cannot be synthesized by humans. Minimum intake levels for essential fatty acids to prevent deficiency symptoms are estimated to be 2.5% E LA plus 0.5% E ALA.

Trans-fatty acids (TFAs)
TFAs from commercial partially hydrogenated vegetable oils (PHVO) increase CHD risk factors and CHD events to a greater extent than what was thought earlier.

(b) Based on epidemiologic studies and randomized controlled trials of CHD events, 6% has been fixed as the minimum recommended consumption level of total PUFA's for lowering LDL and total cholesterol concentrations, increasing HDL cholesterol concentrations and decreasing the risk of CHD events.

(c) Whilst ALA may have individual properties in their own right, there is evidence that the n-3 long chain PUFA's may contribute to the prevention of CHD and possibly other degenerative diseases of aging.

(d) Based on both the scientific evidence and conceptual limitations, there is no compelling scientific rationale for recommending a specific ratio of n-6 to n-3 fatty acids or LA to ALA, especially if intakes of n-6 and n-3 fats lie well outside the recommendations established.

(e) In promoting the removal of TFA, which are predominantly a by-product of industrial processing (partial hydrogenation) usually in the form of PHVO, particular attention must be given to what would be their replacement; this is a challenge for the food industry.

Choice of cooking oils
(9)
Taking into account the contribution of various fatty acids from all foods (visible fats and invisible fats), the complete dependence on just one vegetable oil does not ensure the recommended intake of fatty acids for optimal health. To achieve intake of individual fatty acids, the type of visible fats and correct combination of vegetable oils to be used are as follows:

1. Use correct combination/blend of 2 or more vegetable oils (1:1)

(a) Oil containing LA + oils containing both LA and ALA
Groundnut/Sesame/Rice bran/Cottonseed + Mustard
Repressed
Groundnut/Sesame/Rice bran/Cottonseed + Canola
Groundnut/Sesame/Rice bran/Cottonseed + Soybean
Palmolive + Soybean
Safflower/Sunflower + Palm oil/Palmolive + Mustard
Repressed
(b) Oil containing high LA + oil containing moderate or low LA
Sunflower/Safflower + Palmolive/Palm oil/Olive
Safflower/Sunflower + Groundnut/Sesame/Rice bran/Cottonseed

2. Limit use of butter/ghee
3. Avoid use of PHVO as medium for cooking/frying.
4. Replacements for PHVO
   - Frying: oils which have higher thermal stability – palm, canola, cottonseed – single/blends (home/commercial).

Fat requirements
Recommendations for dietary fats for Indians have been revised taking into account the recent FAO and WHO recommendations for:
(1) Total fat, individual fatty acids and health promoting non-glycemic components;
(2) Source of dietary fats in Indians; and
(3) Availability of fat. The recommendations are directed towards meeting the requirements of optimal foetal and infant growth and development, maternal health and for combating chronic energy deficiency in children and adults, and diet related non-communicable diseases in adults.

Taking into account the unfavourable effect of low fat high carbohydrate diet and the energy requirement set on the basis of age, physiological status and physical activity, the minimum intake of visible fat for Indian adults range between 20-40 g/day. The minimum level of total fat should be 20 per cent of energy. To furnish 30 per cent of total energy, diet of pregnant and lactating mothers should contain at least 30 grams of visible fat (9). For further details see Table 20.

CARBOHYDRATES
The third major component of food is carbohydrate, which is the main source of energy, providing 4 kca/s per gms. Carbohydrate is also essential for the oxidation of fats and for the synthesis of certain non-essential amino acids. There are three main sources of carbohydrates, viz., starches, sugar and cellulose. Starch is basic to the human diet. It is found in abundance in cereals, roots and tubers. Sugars comprise mono and disaccharides (glucose, fructose and galactose) and disaccharides (sucrose, lactose and maltose). These free sugars are highly water soluble and easily assimilated. Free sugars along with starches constitute a key source of energy, Cellulose which is the indigestible component of carbohydrate with scarcely any nutritive value, contributes to dietary fibre.

The carbohydrate reserve (glycogen) of a human adult is about 500 g. This reserve is rapidly exhausted when a man is fasting. If the dietary carbohydrates do not meet the energy needs of the body, proteins and glycogen from dietary and endogenous sources are used by the body to maintain glucose haemostasis.

Glycaemic index
(9)
The glycaemic index of a food is defined by the area under the two-hour blood glucose response curve (AUC) following the ingestion of a fixed portion of test carbohydrate (usually 50 g) as a proportion (%) of the AUC of the standard (either glucose or white bread). Some foods containing different fractions of soluble and

FATS
insoluble fibres favour slow release of sugar into small intestine and its absorption into blood (reduced peak and prolonged rate). They are therefore termed low glycemic index foods as compared to high glycemic foods with readily digestible and absorbable sugar. The concept has practical utility in management of diabetes and control of obesity. The classification of foods according to GI is as follows:

<table>
<thead>
<tr>
<th>Classification</th>
<th>GI range</th>
<th>Examples</th>
</tr>
</thead>
<tbody>

## DİETARY FIBRE

By definition "Dietary fibre is the remnants of the edible part of plants and analogous carbohydrates that are resistant to digestion and absorption in the human small intestine with complete or partial fermentation in the human large intestine". It includes polysaccharides, oligosaccharides, lignin and associated plant substance. Dietary fibre exhibits one or more of either laxation (faecal bulking and softening; increased frequency; and or regularity), blood cholesterol attenuation and/or attenuation of diarrhoea. Organic acids (butyric acid) and polyols (sorbitol) are also considered as part of fibre. Animal foods do not contain any fibre.

### Type and Sources

Dietary fibres have been characterized by its source, e.g., cereal, vegetable and fruits or its solubility in water – soluble (partly or fully) or insoluble. Both characters of solubility are essential for health promotion. Digestibility of fibre is determined by physiochemical and structural properties of the dietary component and the process used. When exposed to longer duration of degradative conditions in large intestine, most fibre is digested. It forms the substance for fermentation by intestinal microbes. It is through this mechanism that part of energy from resistant starch is rendered available. Apart from the energy yielding reactions during digestion, at different pH, the action of enzymes on dietary fibres promotes interaction between nutrients. It also changes the patterns of microbes colonizing the colon and thus the metabolic products of such fermentation over the time. Vegetarians may have different digestion pattern than that of the non-vegetarians and thus derive different health benefits. This knowledge of probiotics characterized by helpful microbes and prebiotics (substrates promoting the colonization of probiotic strains) has opened new areas for research (9).

Original estimates of fibre covered all that was insoluble in boiling water or in dilute acid and alkali conditions. It was reported as ‘crud fibre’, which may include all structural fibre, cellulose, lignin and haemancellulose. It is related to digestibility and has the property of holding water and swelling properties of the diet. It adds to the bulk of the food, favours satiety, increases transit time of the food in the gut and is an active substrate in the large intestine for release of important functional components like organic acids and

nutraeuticals. Mostly complex carbohydrates, such as polysaccharides i.e. cellulose, haemancellulose, pectin and a variety of gums, mucilages form the fibre.

Dietary fibre is known to be associated with reduced incidence of coronary heart disease. The mechanism of its action is attributed to its binding to bile salts and preventing its reabsorption and thus reducing cholesterol level in circulation. The fibre, particularly the gum and pectin, when ingested with a diet, are reported to reduce post-prandial glucose level in blood. Recent studies have shown that gum present in fenugreek seeds, which contains 43 per cent gum, is most effective in reducing blood glucose and cholesterol levels as compared to other gums.

Fibre have no metabolic effects. However, too much of fibre can decrease the absorption of valuable micronutrients. There is conflicting evidence as to whether fibre tends to bind some vitamins and minerals like calcium, magnesium, iron and zinc, and reduce their bio-availability. People who eat well-balanced diet obtain enough roughage. Considering the qualitative and quantitative decrease in fibre content of diet over the past many decades, an increase in dietary fibre, particularly from cereals, emerge as a recommendation. Intake in excess of 60 g of fibre over a day can reduce the nutrient absorption and cause bowel irritation (9). A daily intake of about 40 gms of dietary fibre per 2000 kcal is desirable. The actual quantity of fibre intake depends upon the nature of cereals, pulses, whole grain, vegetables and millets used. The total fibre content of common foods are as shown in Table 4.

VITAMINS

Vitamins are a class of organic compounds categorized as essential nutrients. They are required by the body in very small amounts. They fall in the category of micronutrients. Vitamins do not yield energy but enable the body to use other nutrients. Since the body is generally unable to synthesize them (at least in sufficient amounts) they must be provided by food. A well-balanced diet supplies in most instances the vitamin needs of a healthy person.

Vitamins are divided into two groups: (a) fat soluble vitamins, viz., vitamins A, D, E, and K; and (b) water soluble vitamins, viz., vitamins of the B-group and vitamin C. Each vitamin has a specific function to perform and deficiency of any particular vitamin may lead to specific deficiency diseases. For some vitamins (e.g., vitamin E), no deficiency disease is yet known. The minimum intake for the maintenance of health in respect of many of the vitamins has been determined, but the optimum intake remains somewhat speculative.

VITAMIN A

"Vitamin A" covers both a pre-formed vitamin, retinol, and a pre-vitamin, beta-carotene, some of which is converted to retinol in the intestinal mucosa (17). The international units (IU) originally established for vitamin A and provitamin were discarded in 1954 and 1956 respectively (18). In 1960, the term "retinol" was introduced for vitamin A --1 alcohol (which is available in crystalline form), but most workers prefer the older term vitamin A and the international unit. The international unit (IU) of vitamin A is equivalent to 0.3 microgram of retinol (or 0.55 microgram of retinol palmitate).

Some food composition tables give separate values for retinol and beta-carotene. To convert these into a single value, the term "retinol equivalent" (RE) has been conventionally adopted. The conversion can be done in the following way:

1 mcg of retinol = 1 RE
1 mcg of beta-carotene = 0.167 mcg of RE
1 mcg of other carotenoids = 0.004 mcg of RE

RE = 3.333 IU of Vitamin A

Functions

Vitamin A participates in many bodily functions: (a) is indispensable for normal vision. It contributes to the production of retinal pigments which are needed for vision in dim light. (b) It is necessary for maintaining the integrity and the normal functioning of glandular and epithelial tissue which lines intestinal, respiratory and urinary tracts as well as the skin and eyes. (c) It supports growth especially skeletal growth. (d) It is anti-inflammatory; it has increased susceptibility to infection and lowered immune response in vitamin A deficiency, and (e) it may protect against some epithelial cancers such as bronchial cancers, but the data are not fully consistent (19). However, the role of vitamin A at the molecular level is not yet known.

Sources

- Vitamin A is widely distributed in animal and plant foods -- in animal foods as preformed vitamin A (retinol), and in plant foods as provitamins (carotenoids).

(a) ANIMAL FOODS: Foods rich in retinol are liver, eggs, butter, cheese, whole milk, fish and meat. Fish liver oils are the richest natural sources of retinol (Table 5), but they are generally used as nutritional supplements rather than as food sources.

(b) PLANT FOODS: The cheapest source of vitamin A is green leafy vegetables such as spinach and amaranth which are found in great abundance in nature throughout the year. The darker the green leaf, the higher the carotene content. Vitamin A also occurs in most green and yellow fruits and vegetables (e.g., papaya, mango, pumpkin) and in some roots (e.g., carrots). The most important carotenoid is beta-carotene which has the highest vitamin A activity. Carotenes are converted to vitamin A in the small intestine. This action is poorly accomplished in malnourished children and those suffering from diarrhea.

(c) FORTIFIED FOODS: Foods fortified with vitamin A (e.g., vanaspati, margarine, milk) can be an important source. Vitamin A content of selected foods is as given in Table 5.

The liver has an enormous capacity for storing vitamin A, mostly in the form of retinyl palmitate. Under normal conditions, a well-fed person has sufficient vitamin A reserves to meet his needs for 6 to 9 months or more. Free retinol is highly active, yet toxic and is therefore transported in the blood stream in combination with retinol-binding protein, which is produced by the liver. In severe protein deficiency, decreased production of retinol-binding protein prevents mobilization of liver retinol reserves.

Deficiency

The signs of vitamin A deficiency are predominantly ocular. They include nightblindness, conjunctival xerosis, Bitot's spots, corneal xerosis and keratomalacia. The term "xerophthalmia" (dry eye) comprises all the ocular manifestations of vitamin A deficiency ranging from nightblindness to keratomalacia. Given below is a short description of the ocular manifestations.

(a) Nightblindness

Lack of vitamin A, first causes nightblindness or inability to see in dim light. The mother herself can detect this condition when her child cannot see in late evenings or find her in a darkened room. Nightblindness is due to impairment in dark adaptation. Unless vitamin A intake is increased, the condition may get worse, especially when children also suffer from diarrhea and other infections.

(b) Conjunctival xerosis

This is the first clinical sign of vitamin A deficiency. The
conjecture becomes dry and non-wettable. Instead of looking smooth and shiny, it appears muddy and wrinkled. It has been well described as "emerging like sand banks at receding tide" when the child ceases to cry (21).

(c) Bitot's spots
Bitot's spots are triangular, pearly-white or yellowish, foamy spots on the bulbar conjunctiva on either side of the cornea. They are frequently bilateral. Bitot's spots in young children usually indicate vitamin A deficiency. In older individuals, these spots are often inactive sequelae of earlier disease.

(d) Corneal xerosis
This stage is particularly serious. The cornea appears dull, dry and non-wettable and eventually opaque. It does not have a moist appearance. In more severe deficiency there may be corneal ulceration. The ulcer may heal leaving a corneal scar which can affect vision.

(e) Keratomalacia
Keratomalacia or liquefaction of the cornea is a grave medical emergency. The cornea (a part of the whole) may become soft and may burst open. The process is a rapid one. If the eye collapses, vision is lost.

EXTRA-OCULAR MANIFESTATIONS
These comprise follicular hyperkeratosis, anemia and growth retardation which have long been recognized. They are non-specific and difficult to quantify. Recent studies seem to indicate that early childhood vitamin A deficiency causes an increase in morbidity and mortality due to respiratory and intestine infection (22). Deficiency of vitamin A has recently been linked to child mortality (23).

Treatment
Vitamin A deficiency should be treated urgently. Nearly all of the early stages of xerophthalmia can be reversed by administration of a massive dose (200,000 IU or 110 mg of retinol palmitate) orally on two successive days (24). All children with corneal ulcers should receive vitamin A whether or not a deficiency is suspected.

Prevention
Prevention and/or control takes two forms — (a) improvement of people's diet so as to ensure a regular and adequate intake of foods rich in vitamin A, and (b) reducing the frequency and severity of contributory factors, e.g., PEM, respiratory tract infections, diarrhoea and measles. Both are long term measures involving intensive nutrition education of the public and community participation.

Since vitamin A can be stored in the body for 6 to 9 months and liberated slowly, a short term, simple technology had been evolved by the National Institute of Nutrition at Hyderabad (India) for community based intervention against nutritional blindness which has subsequently been adopted by other countries (25). The strategy is to administer a single massive dose of 200,000 IU of vitamin A in oil (retinol palmitate) orally every 6 months to preschool children (1 year to 6 years), and half that dose (100,000 IU) to children between 6 months and one year of age (24). In this way, the child would be, as it were "immunized" against xerophthalmia. The protection afforded by six-monthly dosing seems very adequate as measured by clinical signs of deficiency (26).

Assessment of vitamin A deficiency
The formulation of an effective intervention programme for prevention of vitamin A deficiency (VAD) begins with the characterization of the problem. This is done by domestic surveys employing both clinical and biochemical criteria. These surveys (prevalence surveys) are done on preschool children (6 months to 6 years) in special areas. The criteria recommended by WHO (18) are as given in Table 6. The presence of any one of the criteria should be considered as evidence of a xerophthalmia problem in the community.

Recommended allowances
The recommended daily intake of vitamin A is 600 micrograms for adults. The present expert committee has modified the extent of conversion efficiency of 1.4 to 1.8 and has retained the previous recommendation on retinol requirements for all age groups except pregnancy. The committee recommends that a minimum of 50 per cent retinol be drawn from animal sources (9). The detailed recommendations are as given in Table 7.

Source: (9)

Toxicity
An excess intake of retinol causes nausea, vomiting, anorexia and sleep disorders followed by skin desquamation and then an enlarged liver and papilla oedema. High
intakes of carotene may colour plasma and skin, but do not appear to be dangerous (19, 27). The teratogenic effects of massive doses of vitamin A is the most recent focus of interest (28).

**VITAMIN D**

The nutritionally important forms of Vitamin D in man are Calciferol (Vitamin D$_3$) and Cholecalciferol (Vitamin D$_2$). Calciferol may be derived by irradiation of the plant sterol, ergosterol. Cholecalciferol is the naturally occurring (preformed) vitamin D which is found in animal fats and fish liver oils. It is also derived from exposure to UV rays of the sunlight which convert the cholesterol in the skin to vitamin D. Vitamin D is stored largely in the fat deposits.

**Vitamin D : Kidney hormone**

Major advances have been made in recent years in our understanding of the metabolism of vitamin D in the body (29). It is now known that vitamin D$_2$ by itself, is metabolically inactive unless it undergoes endogenous transformation into several active metabolites (e.g. 25 HCC: 1: 25 DHCC) first in the liver and later in the kidney. These metabolites are bound to specific transport proteins and are carried to the target tissues — bone and intestine. It has been proposed that vitamin D should be regarded as a kidney hormone (30) because it does not meet the classic definition of a vitamin, that is, a substance which must be obtained by dietary means because of a lack of capacity in the human body to synthesize it. In fact, vitamin D$_2$ is not a dietary requirement at all in conditions of adequate sunlight. It may be synthesized in the body in adequate amounts by simple exposure to sunlight even for 5 minutes per day.

**Functions**

The functions of vitamin D are as summarized in Table 8.

**TABLE 8**

Functions of vitamin D and its metabolites

Source: (31)

**Sources**

Vitamin D is unique because it is derived both from sunlight and foods. (a) **Sunlight** : Vitamin D is synthesized by the body by the action of UV rays of sunlight on 7-dehydrocholesterol, which is stored in large abundance in the skin. Exposure to UV rays is critical; these can be filtered off by air pollution. Dark-skinned races such as Negroes, also suffer from this disadvantage because black skin can filter off up to 95 per cent of UV rays. (b) **Foods** : Vitamin D occurs only in foods of animal origin. Liver, egg yolks, butter, and cheese, and some species of fish contain useful amounts. Fish liver oils, although not considered to be a food, are the richest source of vitamin D. Human milk has been shown to contain considerable amounts of water-soluble vitamin D sulfate (31). Other sources of vitamin D are foods artificially fortified with vitamin D, such as milk, margarine, vanaspati and infant foods. Dietary sources of vitamin D are as given in Table 9.

**Deficiency**

(1) **Rickets** : Vitamin D deficiency leads to rickets, which is usually observed in young children between the age of six months and two years. There is reduced calcification of growing bones. The disease is characterized by growth failure, bone deformity, muscular hypotonia, tetany and convulsions due to hypocalcaemia. There is an elevated deformity index, curving legs, deformed pelvis, pigeon chest, Harrison’s sulcus, rickety rosary, kyphoscoliosis, etc. The milestones of development such as walking and toothing are delayed. (2) **Osteomalacia** : In adults, vitamin D deficiency may result in osteomalacia which occurs mainly in women, especially during pregnancy and lactation when requirements of vitamin D are increased.

Both rickets and osteomalacia are frequently reported in India, although they do not appear to be a problem of public health importance. In the world as a whole, their prevalence has declined as a result of changes in social customs (e.g. purdah system), and the expansion of mother and child health services leading to better care and feeding of infants and children (3). In the developing countries today, rickets as a menace to child health is overshadowed by the prevalence of protein-energy malnutrition.

**Prevention**

Prevention measures include (a) educating parents to expose their children regularly to sunshine; (b) periodic dosing (prophylaxis) of young children with vitamin D; and (c) vitamin D fortification of foods, especially milk. Some industrialized countries still carry out the last measure. Periodic dosing and education appear to be the most practical approaches in developing countries.

**Fraser** (32) urges caution concerning oral supplementation, because orally administered vitamin D appears to bypass the protective mechanism that prevent excessive 25(OH)D$_3$ formation. The margin of safety with oral vitamin D between the nutrient requirement and toxic intake is narrow.

Vitamin D is stored in the body in fatty tissues and is the liver. An excessive intake is harmful and may result in anorexia, nausea, vomiting, thirst, and drowsiness. The patient may lapse into coma, while cardiac arrhythmias and renal failure may occur. The effects are due to hypercalcemia induced by increased intestinal absorption and mobilization of calcium from bone. Recent literature contains warning against the administration of amounts of vitamin D that greatly exceed accepted requirement levels. This warning applies to pregnant women also since manifestations of hypercalcemia may develop in utero (4).

**Daily requirements**

The expert committee of CMR emphasizes importance of outdoor physical activities as a means of achieving adequate vitamin D status in a tropical country like India. However,
under minimal exposure to sunlight, particularly in certain urban groups, like 1-2 year old children, a specific recommendation of a daily supplement of 400 IU (10 mcg) is suggested (9).

VITAMIN E (Tocopherol)

Vitamin E is the generic name for a group of closely related and naturally occurring fat soluble compounds, the tocopherols. Of these alpha-tocopherol is biologically the most potent. Vitamin E is widely distributed in foods. By far the richest sources are vegetable oils, cotton-seed, sunflower seed, egg yolk and butter. Foods rich in polyunsaturated fats are also rich in vitamin E. The usual plasma level of vitamin E in adults is between 0.8 and 1.4 mg per 100 ml (31). While there is no doubt that man requires tocopherol in his diet, there is no clear indication of dietary deficiency. The role of vitamin E at the molecular level is little understood. The current estimate of vitamin E requirement is about 3.8 mg/kg of essential fatty acids. This roughly works out to 8-10 mg tocopherol per day depending on the edible oil used (9).

Recently the cytotoxic effect of vitamin E on human lymphocytes in vitro at high concentrations has been reported. This being so, caution should be exercised against the mega-dose consumption of vitamin E in clinical practice.

VITAMIN K

Vitamin K occurs in at least two major forms – vitamin K1 and vitamin K2. Vitamin K1, found mainly in fresh green vegetables particularly dark green ones, and in some fruits. Cow’s milk is a rich source (60 mcg/L) of vitamin K than human milk (15 mcg/L). Vitamin K1 is synthesized by the intestinal bacteria, which usually provides an adequate supply in man. Long-term administration of antibacterial doses for more than a week may temporarily suppress the normal intestinal flora. A source of vitamin K1 and may cause a deficiency of vitamin K1. Vitamin K1 is stored in the liver.

The role of vitamin K is to stimulate the production and/or the release of certain coagulation factors. In vitamin K deficiency, the prothrombin content of blood is markedly decreased and the blood clotting time is considerably prolonged. The vitamin K requirement of man is met by a combination of dietary intake and microsomal synthesis in the gut. The daily requirement for men appears to be about 0.03 mg/kg for the adult. Newborn infants tend to be deficient in vitamin K due to minimal stores of prothrombin at birth and lack of an established intestinal flora. Soon after birth, all infants or those at increased risk should receive a single intramuscular dose of a vitamin K保住 pregnant (0.1-0.2 mg of menadione sodium bisulfite or 0.5 mg of vitamin K1) by way of prophylaxis (33).

B GROUP OF VITAMINS

THIAMINE (B1)

Thiamine (vitamin B1) is a water-soluble vitamin. It is essential for the utilization of carbohydrates. Thiamine pyrophosphate (TPP), the coenzyme of transketolase plays a part in activating transketolase, an enzyme involved in the direct oxidative pathway for glucose. In thiamine deficiency, there is accumulation of pyruvic and lactic acids in the tissues and body fluids.

Sources

Thiamine occurs in all natural foods, although in small amounts. Important sources are: whole grain cereals, wheat, green vegetables, pulses, oilseeds and nuts, especially peanuts. Meat, fish, eggs, vegetables and fruits contain smaller amounts. Milk is an important source of thiamine for infants, providing a significant proportion of the daily needs. The main source of thiamine in the diet of Indian people is cereals (rice and wheat) which contribute from 50-85 per cent of daily intakes. The thiamine content of selected food stuff is given in Table 10.

Source: (34)

Thiamine losses

Thiamine is readily lost from rice during the process of milling. Being a water-soluble vitamin, further losses take place during washing and cooking of rice. This is the basis for advising people to eschew highly polished rice and eat parboiled or under-milled rice (see page 627). Much of thiamine in fruits and vegetables is generally lost during prolonged storage (30). Thiamine is also destroyed in toasting and in cereals cooked with baking soda. The occurrence or absence of beriberi is determined by the local customs and cultural practices concerned with the processing and cooking of rice and other foodstuffs.

Deficiency

The two principal deficiency diseases are beriberi and Wernicke’s encephalopathy. Beriberi may occur in three main forms: (a) the dry form characterized by nerve involvement (peripheral neuritis); (b) the wet form characterized by heart involvement (cardiac beriberi); and (c) infantile beriberi, seen in infants between 2 and 4 months of age. The affected baby is usually breast-fed by a thiamine-deficient mother who commonly shows signs of peripheral neuropathy. Wernicke’s encephalopathy (very rare in alcoholics) is characterized by ophthalmoplegia, polyneuritis, ataxia and mental deterioration. It occurs occasionally in people who fast. A few short decades ago, frank cases of beriberi used to be frequently seen in the coastal districts of Andhra Pradesh where people eat highly polished rice. Investigations by the ICMS showed that such cases are now rarely encountered because of improved socio-economic conditions and diversification in the diet consumed now (36).

Prevention

Beriberi can be eliminated by educating people to eat well-balanced, mixed diets containing thiamine-rich foods (e.g., parboiled and undermilled rice) and to stop all
alcohol. Direct supplementation of high-risk groups (e.g., lactating mothers) is another approach. Beriberi tends to disappear as economic conditions improve and diets become more varied (10). The disease, as has been shown, is not completely vanquished but the knowledge and resources needed to bring about its disappearance are available (3).

Recommended allowances

The body content of thiamine is placed at 30 mg, and if more than this is given it is merely lost in the urine (19). Patients on regular haemodialysis should routinely be given supplements of thiamine. Thiamine should also be given prophylactically to people with persistent vomiting or prolonged gastric aspiration and those who go on long fasts. For further details see Table 30.

RIBOFLAVIN (B2)

Riboflavin (Vitamin B2) is a member of the B-group vitamins. It has a fundamental role in cellular oxidation. It plays an important role in maintaining the integrity of mucous membranes. It is a co-factor in a number of enzymes involved with energy metabolism. It is also involved in antioxidant activity, being a co-factor for the enzymes like glutathione reductase and is required for the metabolism of other vitamins like vitamin B6, niacin and vitamin K (9).

Sources

Its richest natural sources are milk, eggs, liver, kidney and green leafy vegetables. Meat and fish contain small amounts. Cereals (whether whole or milled) and pulses are relatively poor sources but because of the bulk in which they are consumed, they contribute much of the riboflavin to Indian diets. Germination increases the riboflavin content of pulses and cereals. The riboflavin content of some common foods is given in Table 11.

Source: (34)

Deficiency

The most common lesion associated with riboflavin deficiency is angular stomatitis, which occurs frequently in malnourished children and its prevalence is used as an index of the state of nutrition of groups of children (31). Other clinical signs suggestive (but not specific) include cheilosis, glossitis, nasolabial dysesthesia, etc. Hypo-riboflavinosis, even when severe, seldom incapacitates the individual, but it may have some functional effects such as impaired neuromotor function, wound healing and perhaps increased susceptibility to cataract (37). Riboflavin deficiency almost always occurs in association with deficiencies of other B-complex vitamins such as pyridoxine; it is usually a part of a multiple deficiency syndrome.

Requirement

There are no real body stores of riboflavin. Daily requirement is 0.6 mg per 1000 kcal of energy intake (9). For further details see Table 30.

NIACIN (B3)

Niacin or nicotinic acid (B3) is essential for the metabolism of carbohydrate, fat and protein. It is also essential for the normal functioning of the skin, intestinal and nervous systems. This vitamin differs from the other vitamins of the B-complex group in that an essential amino acid, tryptophan, serves as its precursor. Another characteristic of this vitamin is that it is not excreted in urine as such, but is metabolized to at least 2 major methylated derivatives: N-methyl nicotinamide and N-methyl pyridine.

Sources

Foods rich in niacin and/or tryptophan are liver, kidney meat, poultry, fish, legumes and groundnut. Milk is a poor source of niacin but its proteins are rich in tryptophan which is converted in the body into niacin (about 60 mg of tryptophan is required to result in 1 mg of niacin). In many cereals, especially maize, niacin occurs in “bound” form unavailable to the consumer.

Deficiency

Niacin deficiency results in pellagra. The disease is characterized by three D’s – dermatitis, diarrhoea and dementia. In addition glossitis and stomatitis usually occur. The dermatitis is bilaterally symmetrical and is found only on those surfaces of the body exposed to sunlight, such as back of the hands, lower legs, face and neck. Mental changes may also occur which include depression, irritability and delirium.

Once a formible and widespread deficiency disease among malnourished population subsisting mainly on maize diets, pellagra has declined in all parts of the world. It is still prevalent in some parts of Western Asia and Southern Africa where people subsist on maize and little else (38). While pellages is historically a disease of the maize-eating population, it was reported in India in the Telangana area of Andhra Pradesh in some segments of the population eating another cereals – that is jowar (Sorghum vulgare), these people consuming very little of milk or other foods of animal origin. Studies by Gopalani and others (39) have shown that amino acid balance caused by an excess of legume is the cause of pellagra in both jowar and maize eaters. Excess of legume appears to interfere in the conversion of tryptophan to niacin.

Prevention

Pellagra is a preventable disease. A good mixed diet containing milk and/or meat is universally regarded as an essential part of prevention and treatment. Avoidance of total dependence on maize or sorghum is an important preventive measure. Pellagra is a disease of poverty. With modern knowledge and opportunities for economic, agricultural and social development, there is every reason to hope that this disease could be eliminated (3).

Requirement

The recommended daily allowance is 6.0 mg/1000 kcal of energy intake (9). For further details see Table 30.
PYRIDOXINE (B6)

Pyridoxine (vitamin B6) exists in three forms: pyridoxine, pyridoxal and pyridoxamine. It plays an important role in the metabolism of amino-acids, fats and carbohydrate. It is widely distributed in foods, e.g., milk, liver, meat, egg yolk, fish, whole grain cereals, legumes and vegetables. Pyridoxine deficiency is associated with peripheral neuritis. Riboflavin deficiency impairs the optimal utilization of pyridoxine (ANH, an antithyroid drug) is a recognized antagonist, and patients receiving ANH are provided with a supplement of pyridoxine (10 mg/day).

There is no known specific requirement for vitamin B6. All foods contribute to dietary intake. About 3 mg are excreted daily in urine.

PANTOTHENIC ACID (B5)

There is a long standing evidence for a relation between pantothenic acid and adrenal cortical function. Work indicates a more specific role for pantothenic acid in the biosynthesis of corticosteroids (7). Human blood normally contains 18 to 35 mg of pantothenic acid per 100 ml, mostly present in the cells as coenzyme A. The daily requirement is set at 10 mg (2). All foods contribute to dietary intake. About 3 mg are excreted daily in urine.

FOLATE

The recommended name is folic acid, alternative name is folacin and the usual pharmaceutical preparation is folic acid (folic 19).

Folic acid occurs in food in two forms: free folic acid and bound folic acid. The total folic acid represents both the groups. In man, free folic acid is rapidly absorbed, primarily from the proximal part of small intestine. The availability of bound folic acid is uncertain. Folic acid plays a role in the synthesis of the nucleic acids of digastric cells. It is also needed for normal growth of blood cells in the marrow.

Sources

The name comes from the Latin folium (= leaf) but foods such as liver, meat, dairy products, eggs, milk, fruits and cereals are as good dietary sources as leafy vegetables. Overcooking destroys much of folic acid and thus contributes to folate deficiency in man. Folate deficiency has been reported in babies given milk foods subjected to heat sterilization.

Deficiency

Folate deficiency may occur simply from a poor diet. It is commonly found in pregnant and lactation (40) where requirements are increased. It results in megaloblastic anaemia, glossitis, cheilosis and gastrointestinal disturbances such as diarrhoea, distension and flatulence. Severe folate deficiency may cause infertility or even sterility. There is also evidence that the administration of folic acid antagonists (e.g., alcohol, pyrimethamine, and cotrimoxazole) in early pregnancy may produce abortions or congenital malformations.

The laboratory diagnosis of folate deficiency is based on measurement of serum and red cell folate concentrations, usually by microbiological assay (41).

Requirement

Body stores of folate are not large, about 5-10 mg, and therefore, folate deficiency can develop quickly. Folic acid requirements are greatest in conditions where there is rapid cell multiplication, such as during growth in young children and during pregnancy (41). Folic acid supplementation during pregnancy has been found to increase the birth weight of infants and decrease the incidence of low birth weight babies. Intake values recommended by ICNIR (1970) are given below:

<table>

VITAMIN B12

Vitamin B12 is a complex organo-metallic compound with a covalent bond. The preparation which is therapeutically used is cyanocobalamin, which is relatively cheap. Vitamin B12 cooperates with folate in the synthesis of DNA, so deficiency of either leads to megaloblastosis. Vitamin B12 has a separate biochemical role, unrelated to folate, in the synthesis of fatty acids in myelin (19). The physiological mechanism for its absorption requires intrinsic factor from the stomach, and the complex is absorbed only at a special site in the terminal ileum.

Sources

Good sources are liver, kidney, meat, fish, eggs, milk and cheese. Vitamin B12 is not found in foods of vegetable origin. It is also synthesized by bacteria in colon. Unlike folic acid, vitamin B12 is relatively heat-stable. Liver is the main storage site of vitamin B12. About 2 mg are stored in liver, and another 2 mg elsewhere in the body. These stores are sufficient to tide over any deficiency for one to three years. Because of these reserves, deficiency of vitamin B12 appears to be rare.

Deficiency

Vitamin B12 deficiency is associated with megaloblastic anaemia (pernicious anaemia), demyelinating neurological lesions in the spinal cord and infertility (in animal species), which is rarely seen in India. While clinical deficiency of B12 is not manifested, sub-clinical deficiency is reported to exist in India. Reports indicate that there exist more than 30 per cent deficiency in adults and children in the country. It is not surprising that blood levels of vitamin B12 are low, since a large proportion of population depends on plant food for nutrients (9).

Requirement

Intake values recommended by ICNIR (2010) are as below (9):

<table>

VITAMIN C

Vitamin C (ascorbic acid) is a water-soluble vitamin. It is the most sensitive of all vitamins to heat. Meat, monkey and guinea pig are perhaps the only species known to require vitamin C in their diet.

Functions

Vitamin C is a potent antioxidant and has an important role in tissue oxidation. It is needed for the formation of collagen, which accounts for 25 per cent of total body protein (7). Collagen provides a supporting matrix for the blood vessels and connective tissue, and for bones and cartilage. That explains why in vitamin C deficiency this support fails, with the result that local hematomas develop and the bones fracture easily. Vitamin C, by reducing ferric iron to ferrous iron, facilitates the absorption of iron from vegetable foods. It inhibits nitrosamine formation by the intestinal mucosa. Other claims such as prevention of common cold and protection against infections are not substantiated.

Sources

The main dietary sources of vitamin C are fresh fruits and green leafy vegetables. Traces of vitamin C occur in fresh meat and fish but scarcely in cereals. Germinating pulses contain good amounts. Roots and tubers contain small amounts. Amla or the Indian gooseberry is one of the richest sources of vitamin C both in the fresh as well as in the dry condition. Guava are another cheap but rich source of this vitamin. The dietary sources of vitamin C are as given in Table 12.

Source: (34)

Deficiency

Deficiency of vitamin C results in scurvy, the signs of which are swollen and bleeding gums, subcutaneous bruising or bleeding into the skin or joints, delayed wound healing, anaemia and weakness. Scurvy, which was once an important deficiency disease is no longer a disease of world importance (3).

Requirement

The estimated requirement for vitamin C is 40 mg per day for adults. The normal body, when fully saturated contains about 5 g of vitamin C. Daily intakes recommended by the ICMR (9) are as given in Table 30.

MINERALS

More than 50 chemical elements are found in the human body, which are required for growth, repair and regulation of vital body functions. These can be divided into three major groups: (a) MAJOR MINERALS: These include calcium, phosphorus, sodium, potassium and magnesium. (b) TRACE ELEMENTS: These are elements required by the body in quantities of less than a few milligrams per day, e.g., iron, iodine, fluorine, zinc, copper, cobalt, chromium, manganese, molybdenum, selenium, nickel, tin, silicon and vanadium (41). Many more have been added to the list in the last few years. (c) TRACE CONTAMINANTS WITH NO KNOWN FUNCTION: These include lead, mercury, barium, bismuth, and aluminium.

Only a few mineral elements (e.g., calcium, phosphorus, sodium, iron, fluorine, iodine) are associated with clearly recognizable clinical situations in man. For none of the other elements do we know with any certainty for their metabolic roles, and much less the clinical effects of dietary insufficiency (45). The bio-availability of minerals such as iron and zinc may be low in a total vegetarian diet because of the presence of substances such as phytic acid. Besides, large amounts of dietary fibre may interfere with proper absorption. Man is not likely to suffer from trace element deficiencies as long as he is omnivorous. Surveys have shown that mineral deficiencies are no greater among vegetarians than among non-vegetarians. In fact, man's need for trace elements has not yet been precisely determined. Trace elements should not be used as dietary supplements, since excessive amounts can have injurious effects.

CALCIUM

Calcium is a major mineral element of the body. It constitutes 1.5-2 per cent of the body weight of an adult human. An average adult body contains about 1200 g of calcium, which over 70 per cent is found in the bones. The amount of calcium in the blood is usually about 10 mg/dl. The developing foetus requires about 30 g of calcium. There is a dynamic equilibrium between the calcium in the blood and that in the skeleton; this equilibrium is maintained by the interaction of vitamin D, parathyroid hormone, and probably calcitonin.

Functions

Iodised calcium in the plasma has many vital functions including formation of bone and teeth, coagulation of blood, contraction of muscles, cardiac action, milk production, relay of electrical and chemical messages that arrive at a cell's surface membrane to the biochemical machinery within the cell, keeping the membranes of cells intact and in the metabolism of enzymes and hormones. It also plays a crucial role in the transformation of light to electrical impulses in the retina. In short, the calcium ion controls man's life processes ranging from muscle contraction to cell division.

Sources

Calcium is readily available from many sources. By far the best natural sources are milk and milk products (e.g., cheese, curd, skimmed milk and butter milk), eggs and fish. A litre of cow's milk provides about 1250 mg of calcium, and human milk about 300 mg. Calcium occurs in milk as
calcium caseinogenate which is readily assimilated by the body. The cheapest dietary sources are green leafy vegetables, cereals and millets. The limiting factor in the complete absorption of calcium from green leafy vegetables (e.g., spinach, amaranth) is the presence of oxalic acid with which calcium forms an insoluble compound, calcium oxalate which interferes with the absorption of calcium. Most cereals are generous providers of calcium, and the millet "ragi" is particularly rich in calcium. Rice is very deficient in calcium (43). The bioavailability of calcium from cereals is poor because of the presence of phytic acid which forms an insoluble compound with calcium, calcium phytate. An additional source of calcium is drinking water which may provide up to 200 mg/day. Some fruits (e.g. Sitaphal) contain good amounts of calcium.

Absorption
Overall, about 20–30 per cent of dietary calcium is normally absorbed. Absorption of calcium is enhanced by vitamin D and decreased by the presence of phytates, oxalates and fatty acids in the diet. Calcium absorption is regulated to some extent by the body's needs.

Deficiency
No clear-cut disease due to calcium deficiency has ever been observed, even under conditions of low intake (44). It has been established that if the intake of vitamin D is adequate, the problems of rickets and osteomalacia do not arise even with low calcium intake. On the other hand, no deleterious effects have been observed in man as a result of prolonged intakes of large amounts of dietary calcium, neither have any benefits been demonstrated.

Requirement
A daily intake of 600 mg of calcium has been suggested for adults (9). The physiological requirements are higher in children, expectant and nursing mothers. Intake values recommended by ICMR (9) are as given in Table 29.

PHOSPHORUS
Phosphorus is essential for the formation of bones and teeth. It plays an important part in all metabolisms. An adult human body contains about 400–700 g of phosphorus as phosphates, most of this occurs in bones and teeth. Phosphorus is widely distributed in foodstuffs; its deficiency rarely occurs. A large part of phosphorus present in vegetable foods occurs in combination with phytin and is available to the body only to the extent of 40–60 per cent. Phosphorus requirements have not been specifically considered by FAO/WHO Committees, but other groups of experts have suggested that phosphorus intake should be at least equal to calcium intakes in most age groups, except in infancy where the ratio suggested is 1.1:5 (9).

SODIUM
Sodium is found in all body fluids. The adult human body contains about 100 g of sodium ion. Sodium occurs in many foods, and is also added to food during cooking in the form of sodium chloride. Sodium is lost from the body through urine and sweat; that which is passed out in urine is regulated by the kidney but that which is lost by sweating is not controlled. Depletion of sodium chloride causes muscular cramps. The requirement of sodium chloride depends upon climate, occupation, and physical activity. Adult requirement is about 5 g per day. A strong relationship between hypertension and dietary salt intake has been observed and intake of more than 10 g of salt per day is considered to have defensive tendency to raise blood pressure (9).

POTASSIUM
The adult human body contains about 250 g of potassium. Potassium occurs widely in foodstuffs, so there is little likelihood of its deficiency. Potassium is vasoactive, increases blood flow and sustains metabolic needs of the tissue. Potassium is released by endothelial cells. Potassium supplements lower blood pressure, although the response is slow. Much of the information regarding potassium and blood pressure is in relation to dietary sodium. High dietary sodium, low dietary potassium have been implicated in the aetiology of hypertension as evidenced by epidemiological clinical studies (9).

The ideal desirable sodium : potassium ratio in the diet is 1:1 (in mmol).

MAGNESIUM
Magnesium is a constituent of bones, and is present in all body cells. Human adult body contains about 25 g of magnesium of which about half is found in the skeleton. It appears that magnesium is essential for the normal metabolism of calcium and potassium (45). Magnesium deficiency may occur in chronic alcoholics, cirrhosis of liver, toxemias of pregnancy, protein-energy malnutrition and malabsorption syndrome (46). The principal clinical features attributed to magnesium deficiency are irritability, tetany, hypo-reflexia and occasionally hyper-reflexia. Requirements are estimated to be about 340 mg/day for adults (9). For details see Table 29.

IRON
Iron is of great importance in human nutrition. The adult human body contains between 3–4 g of iron, of which about 60–70 per cent is present in the blood (Hb iron) as circulating iron, and the rest (1 to 1.5 g) as storage iron. Each gram of haemoglobin contains about 3.34 mg of iron.

Functions
Iron is necessary for many functions in the body including formation of haemoglobin, brain development and function, regulation of body temperature, muscle activity, and catecholamine metabolism. Lack of iron directly affects the immune system; it diminishes the number of T-cells and the production of antibodies. Besides haemoglobin, iron is a component of myoglobin, the cytochromes, catalase and certain enzyme systems. Iron is essential for binding oxygen to the blood cells. The central function of iron is "oxygen transport", and cell respiration.

Sources
There are two forms of iron, haem-iron and non-haem iron. Haem-iron is better absorbed than non-haem iron. Foods rich in haem-iron are liver, meat, poultry and fish.
They are not only important sources of readily available iron but they also promote the absorption of non-jaem iron in plant foods eaten at the same time (47). The iron content of milk is low in all mammalian species. Iron content of breast milk averages less than 0.2 mg/dl, and it is well utilized. Foods containing non-jaem iron are those of vegetable origin, e.g., cereals, green leafy vegetables, legumes, nuts, olives, figs, and dried fruits. They are important sources of iron in the diets of a large majority of Indian people. The bioavailability of non-jaem iron is poor owing to the presence of phytates, oxalates, carbonates, phosphates and dietary fibre which interfere with iron absorption. Other foods which inhibit iron absorption are milk, eggs and tea (48). The Indian diet which is predominantly vegetarian contains large amounts of these inhibitors, e.g., phytates in bran, phosphates in egg yolk, tannins in tea and oxalates in vegetables. In some areas, significant amounts of iron may be derived from cooking in iron vessels.

Absorption
Iron is mostly absorbed from duodenum and upper small intestine in the ferrous state, according to body needs. The rate of iron absorption is influenced by a great many factors like iron reserves of the subjects, the presence of inhibitors (e.g., phytates), and promoters (e.g., ascorbic acid and ascorbic acid-rich foods) of iron absorption, and disorders of duodenum and jejunum (e.g., coeliac disease, tropical sprue). Iron absorption is greater when there is an increased demand for iron, as for example during pregnancy (17). Iron absorption from habitual Indian diets is less than 5 per cent (17), the bioavailability being poor. Absorbed iron is transported as plasma ferritin and stored in liver, spleen, bone marrow and kidney. The characteristic feature of iron metabolism is conservation. When red cells are broken down, the liberated iron is reutilized in the formation of new red cells.

Iron losses
The total daily iron loss of an adult is probably 1 mg, and about 12.5 mg per 28 days cycle in menstruating women. Major routes of iron loss are: (a) through haemorrhage, that is, wherever blood is lost, iron is lost, the causes of which may be physiological (e.g., menstruation, childbirth) or pathological (e.g., haemorrhoids, malaria, haemorrhoids, peptic ulcer); (b) basal losses, such as excretion through urine, sweat and bile, and desquamated surface cells. The widespread use of IUDs in the family planning programme is an additional cause of iron loss. IUDs have been shown to increase the average monthly blood loss by between 35 and 146 per cent depending upon the type of the device (49, 50). Hormonal contraceptives, on the other hand, decrease menstrual blood loss by about 50 per cent (51).

Iron deficiency
Three stages of iron deficiency have been described: (a) First stage characterized by decreased storage of iron with or without other detectable abnormalities. (b) An intermediate stage of "latent iron deficiency", that is, iron stores are exhausted, but anaemia has not occurred as yet. Its recognition depends upon measurement of serum ferritin levels. The percentage saturation of transferrin falls from a normal value of 80 per cent to less than 15 per cent. This stage is the most wide-spread prevalent stage in India. (c) The third stage is that of overt iron deficiency when there is a decrease in the concentration of circulating haemoglobin due to impaired haemoglobin synthesis (49).

The end result of iron deficiency is nutritional anaemia which is not a disease entity. It is rather a syndrome caused by malnutrition in its widest sense (51). Besides anaemia, there may be other functional disturbances such as impaired cell-mediated immunity, reduced resistance to infection, increased morbidity and mortality and diminished work performance.

Diagnosis of anaemia
A WHO Expert Group (52) proposed that "anaemia of deficiency should be considered to exist" when haemoglobin is below the following levels (see Table 13).

<table>
<thead>
<tr>
<th>g/dl (Venous blood)</th>
<th>MCHC (per cent)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adult males</td>
<td>13</td>
</tr>

</tr>
<tr>
<td>Children, 6 months to 6 years</td>
<td>11</td>
</tr>
<tr>
<td>Children, 6 to 14 years</td>
<td>12</td>
</tr>
</tbody>
</table>

At all ages the normal MCHC should be 34; values below that indicate that red cells are hypochromic, which occurs in iron deficiency anaemia. A haemoglobin level of 10 to 11 g/dl has been defined as early anaemia; a level below 10 g/dl as marked anaemia (53).

EVALUATION OF IRON STATUS
Evaluation of iron status is based on the following parameters:

(a) Haemoglobin concentration: Values below those given in Table 14 indicate anaemia. Haemoglobin concentration is a relatively insensitive index of nutrient depletion. Its value is less in populations 'n which anaemia is not severe. This is because anaemia is a late manifestation of iron deficiency which can frequently occur without the manifestation of anaemia (52).

(b) Serum iron concentration: This is a more useful index than haemoglobin concentration. The normal range is 0.80 to 1.80 mg/L; values below 0.50 mg/L indicate probable iron deficiency (54).

(c) Serum ferritin: The single most sensitive tool for evaluating the iron status is by measurement of serum ferritin. It reflects the size of iron stores in the body. It is the most useful indicator of iron status in a population where the prevalence of iron deficiency is not high. Values below 10 mcg/L probably indicate an absence of stored iron (19).

(d) Serum transferrin saturation: This should be above 16 per cent. Normal value is 30 per cent.

Iron requirements
Because of the recycling of iron, only a small amount of iron is needed by the body. In general, iron requirements are greater when there is rapid expansion of tissue and red cell mass, as for example during pregnancy, childhood, adolescence. Table 14 shows the recommended daily intakes.

</table>

It can be seen from Table 15 that the problem of IDD is of far greater magnitude than one of goitre and cretinism. It is a national problem with grave socio-economic consequences. Adequate technology exists for the successful prevention of iodine deficiency disorders (see page 643).

Requirement

The daily requirement of iodine for adults is placed at 150 micrograms. The recommendations of WHO of 250 mcg per day for iodine during pregnancy have also been adopted. This amount is normally supplied by well-balanced diet and drinking water except in regions where food and water are deficient in iodine.

Epidemiological assessment of iodine deficiency

This is necessary before initiating an iodisation programme, and for surveillance of goitre control.
programmes. The following indicators are useful in this regard (58):

- prevalence of goitre
- prevalence of cretinism
- urinary iodine excretion
- measurement of thyroid function by determination of serum levels of thyroxine (T₄) and pituitary thyrotropic hormone (TSH), and
- prevalence of neonatal hypothyroidism.

Since the objective of goitre control programme is to increase iodine intake, indices of urinary excretion are particularly recommended for use in surveillance. Neonatal hypothyroidism has been found to be a sensitive indicator of environmental iodine deficiency. Serum T₄ level is a more sensitive indicator of thyroid insufficiency than T₃.

**FLUORINE**

Fluorine is the most abundant element in nature. Being so highly reactive, it is never found in its elemental gaseous form, but only in combined form. About 96 per cent of the fluorides in the body is found in bones and teeth. Fluorine is essential for the normal mineralization of bones and formation of dental enamel.

**Sources**

The principal sources of fluorine available to man are:

(a) **Drinking water**: The major source of fluorine to man is drinking water. In most parts of India, the fluoride content of drinking water is about 0.5 mg/l, but in fluorosis-endemic areas, it may be as high as 3 to 12 mg/l (59).

(b) **Foods**: Fluorides occur in traces in many foods, but some foods such as sea fish, cheese and tea are reported to be rich in fluorides (38).

**Deficiency/excess**

Fluorine is often called a two-edged sword. Prolonged ingestion of fluorides through drinking water in excess of the daily requirement is associated with dental and skeletal fluorosis; and inadequate intake with dental caries. The use of fluorides is recognized as the most effective means available for the prevention of dental caries.

**Requirements**

The recommended level of fluorides in drinking water in India is accepted as 0.5 to 0.8 mg per litre (60, 61). In temperate countries where the water intake is low, the optimum level of fluorides in drinking water is accepted as 1 to 2 mg per litre (62).

**OTHER TRACE ELEMENTS**

**Zinc**

Zinc is a component of more than 300 enzymes. It is active in the metabolism of glycides and proteins, and is required for the synthesis of insulin by the pancreas and for the immunity function. Zinc is present in small amounts in all tissues. Zinc-plasma level is about 96mg per 100 ml for healthy adults, and 89 mg per 100 ml for healthy children (63). The average adult body contents 1.4 to 2.3 g of zinc (64). Zinc deficiency has been reported to result in growth failure and sexual infantilism in adolescents, and in loss of taste and delayed wound healing (10). There are also reports of low circulatting zinc levels in clinical disorders such as liver disease, pernicious anaemia, thalassaemia and myocardial infarction. Zinc deficiency is common in children from developing countries due to lack of intake of animal food, high dietary phytate content, inadequate food intake and increased faecal losses during diarrhoea. Zinc supplementation in combination with other nutritional therapy has been shown to significantly reduce the duration and severity of acute and persistent diarrhoea and to increase survival in a number of randomized control trials. Adequate zinc intake is essential for maintaining the integrity of immune system. Zinc affects multiple aspects of the immune system, from the barrier of the skin to gene regulation within lymphocytes. Severe maternal zinc deficiency has been associated with spontaneous abortion and congenital malformations like anencephaly. Mild forms of zinc deficiency has been associated with low birth weight, intrauterine growth retardation and preterm delivery. Several studies have indicated that zinc supplementation may reduce the incidence of clinical attacks of malaria in children. Zinc plays an important role as antioxidant agent (65). These reports suggest that zinc deficiency may not be uncommon in man (66). Zinc is widely distributed in foodstuffs, both animal and vegetable — but the bioavailability of zinc in vegetable foods is low. Animal foods such as meat, milk and fish are dependable sources. Suggested daily intake for adults is 12 mg per day for men, 10 mg per day for women, 10 mg per day for children and 5 mg for infants. Refer to Table 29 for details. Growing children and pregnant and lactating women need more. Most human diets provide these amounts.

**Copper**

The amount of copper in an adult body is estimated to be between 100-150 mg. Copper is widely distributed in nature and is an important component of many enzymes that function in the body. Deficiency or excess of this element is very rare. Hypocupremia occurs in patients with nephrosis. Wilson's disease and protein-energy malnutrition and in infants fed for long periods exclusively on cow's milk. Neutropenia is the best documented abnormality of copper deficiency. Hypocupremia may reflect excessive intake which may result from eating food prepared in copper cooking vessels, or it may be associated with several acute and chronic infections (leukaemia, Hodgkin's disease, severe anaemia, haemochromatosis, myocardial infarction and hyperthyroidism (66)). Estimated copper requirement for adults is about 2.0 mg per day.

**Coalt**

The only established function of cobalt in the human is as a part of the vitamin B₁₂ molecule, which must be ingested preformed. There is no evidence as yet of cobalt deficiency in man (10). Recently cobalt deficiency and cobalt iodine ratio in the soil have shown to produce goitre in humans. It is suggested that cobalt may be necessary for the first stage of hormone production, i.e., capture of iodine by the gland (67). Cobalt may interact with iodine and affect its utilization (10).

**Chromium**

Total body content of chromium is small, less than 6 mg. Current interest in chromium is based on the occurrence of unusual glucose tolerance curves that are responsive to chromium (41). Thus there is suggestive evidence that chromium plays a role in relation to carbohydrate and insulin function (10).
Selenium
Little attention had been given earlier to selenium in human nutrition. The first report of selenium deficiency may occur in man appeared in 1961, and a similar report in 1967. Selenium administration to children with kwashiorkor resulted in significant weight increase. Studies indicate that human selenium deficiency may occur in protein-energy malnutrition (66). Selenium deficiency especially when combined with vitamin E deficiency, reduces antibody production (68).

Molybdenum
Excess absorption of molybdenum has been shown to produce bony deformities. On the other hand, deficiency of molybdenum is associated with mouth and esophageal cancers (7).

Dietary antioxidants (9)
Antioxidants are substances which are both nutritive, viz. vitamins E, C, β-carotene, selenium, and non-nutritive, viz. plant phenols, flavonoids, coumarins, benzoic acid, naphthoquinones, catechic, ferric, gallic and ellagic acids, some enzymes like superoxide dismutase and catalase superoxide mutase. These antioxidants reduce the adverse effects of reactive oxygen species (ROS) and nitrogen species which are generated during physiological or pathological conditions and result in oxidant damage. Literature is replete with evidence that ageing and several diet/investigational related chronic disorders are due to chronic exposure to ROS. It is well established that vegetables, fruits, legumes, spices, beverages such as tea and wine, and cereals are excellent sources of AO, however scientific evidence for their protective role is available only for vegetables and fruits in several chronic disorders. Note that the randomized clinical trials conducted so far with nutrient AO supplements has demonstrated a significant benefit in community trials barring one or two major trials in high-risk populations.

Experimental studies have amply indicated that both pro-oxidant and AO have a fundamental role in pathogenesis of diseases. Reactive oxygen species (ROS) damage the bio-molecular such as DNA, protein, carbohydrates and lipids, and affect the enzyme processes and genetic machinery. The oxidation products of bio-molecules accumulate with age. ROS can be derived from an environmental source also. There are several endogenous and exogenous sources of ROS, which play an important role in diseases such as cardiovascular, cancer, cataract, diabetes, neuro-degenerative disorders and age-related maculopathy. Chronic infections aggravate the damage. Further, research in this field has highlighted the mechanistic details about the role of antioxidants in mitigating the damage.

Free radicals produced during tissue metabolism and their consequent damage are reduced by nutrients antioxidants. The antioxidants, particularly vitamin E, C, co-enzyme and glutathione seem to work in concert by recycling each other.

In healthy subjects, the dietary antioxidants from a balanced diet with adequate fruits and vegetables ranging from 500-600 gm/d will probably be enough to take care of oxidant damage and repair cellular and tissue defects. However, certain groups of populations like pre-mature infants, smokers, alcoholics, and those exposed to environmental pollutants including carcinogens, individuals with chronic infections as well as those engaged in strenuous physical activity and geriatric population, are at high-risk of oxidant damage.

At present the amount of antioxidants to be consumed daily to protect against risk factors cannot be quantitatively fixed (9).

NUTRITIONAL PROFILES OF PRINCIPAL FOODS
When planning balanced diets, it is important to know what foods are available according to origin, approximate chemical composition, predominant function and how to combine them to increase nutritive value. Since each food has a different nutritional profile, an intake of different types of foods is desired to achieve optimum health.

1. Cereals and millets

CEREALS
Cereals (e.g., rice, wheat) constitute the bulk of the daily diet. Rice is the staple food of more than half the human race. Next to rice, wheat is the most important cereal. Maize ranks next to rice and wheat in world consumption. Maize is also used as food for cattle and poultry because it is rich in fat, besides being cheaper than rice or wheat.

Cereals are the main sources of energy (carbohydrates). They also contribute significant quantities of proteins (6 to 12 per cent), minerals and B-group vitamins. The yellow variety of maize contains significant amounts of carotene. In terms of energy, cereals provide about 350 kcal per 100 grams. Considering the large amounts in which they are consumed, cereals contribute 70 to 80 per cent of the total energy intake, and more than 50 per cent of protein intake in typical Indian diets.

Cereal proteins are poor in nutritive quality, being deficient in the essential amino acid, lysine. The proteins of maize are still poorer, being deficient in lysine and tryptophan (a precursor of niacin). However, if cereals are eaten with pulses, as is common in the traditional Indian diets, cereal and pulse proteins complement each other and provide a more balanced and "complete" protein intake. Some strains of maize contain an excess of leucine which interferes with the conversion of tryptophan into niacin; this aggravates the pellagragetic action of maize.

Table 16 gives the nutritive value of some common cereals.

</table>
Rice

Rice is the staple food of more than half the human race. The rice grain consists of 3 parts – the germ (embryo), the inner endosperm, and the outer pericarp and aleurone grain layer. The endosperm is composed mostly of starch; the outer pericarp aleurone layer and germ contain most of the essential nutrients. The protein content of rice varies from 6–9 per cent. Rice proteins are richer in lysine than the other cereal proteins, and for this reason, rice protein is considered to be of better quality. Rice is a good source of B group vitamins, especially thiamine. It is devoid of vitamins A, D and C. In regard to minerals rice is a poor source of calcium and iron (Table 17).

</tr>
</tbody>
</table>

**Effect of milling**

The milling process depletes the rice grain of its valuable nutritive elements (thiamine, riboflavin, protein). The losses may be up to 15 per cent of protein, 75 per cent of thiamine and 60 per cent of riboflavin and niacin (69). The resulting white or polished rice, although attractive in appearance, is poor in nutritive value. People subsisting mainly on white or polished rice are prone to beriberi, the best known deficiency disease of rice eaters. Nutrition workers therefore advocate under-milled or “parboiled” rice in place of white rice.

**Washing and cooking**

The rice grain is subjected to further loss of essential nutrients during the process of washing and cooking. Washing in large quantities of water would remove up to 60 per cent of the water-soluble vitamins and minerals. The practice of cooking rice in large quantities of water and draining away the excess of water at the end of cooking leads to further loss of B-group vitamins. Thus the combined effect of washing and cooking may affect seriously the nutritive value of rice. It is therefore best to cook rice in just enough water (about 2 measure of water for 1 measure of rice).

**Parboiling**

Parboiling (partial cooking in steam) is ancient Indian technique of preserving the nutritive quality of rice. There are many techniques of parboiling. The technique recommended by the Central Food Technological Research Institute, Mysore (8) is known as the hot soaking process.

The process starts with soaking the paddy (unhulled rice) in hot water at 65 to 70 deg. C for 3 to 4 hours, which swells the grain. This is followed by draining of water and steaming the soaked paddy in the same container for 5 to 10 minutes. The paddy is then dried and later homogenized or milled.

During the steaming process, a greater part of the vitamins and minerals present in the outer aleurone layer of the rice grain are driven into the inner endosperm. With subsequent milling, even at a high degree, the nutrients are not removed. During the drying process, the germ gets attached more firmly to the grain. In addition, the heat used in drying hardens the rice grain. It results in the grain becoming more resistant to insect invasion and more suitable for storage than raw rice. The starch also gets gelatinized which improves the keeping quality of rice (8). The serious disadvantage of parboiling is the development of a peculiar smell or “off flavour” which some consumers do not relish. Modern methods of parboiling rice have been developed by which the finished product does not give any bad odour.

**Wheat**

Next to rice, wheat is the most important cereal. The nutritive composition of wheat is given in Table 16. The protein content of wheat varies from 9 to 16 per cent, the limiting amino-acids are lysine and threonine. The wheat grain is much less subjected to loss of essential nutrients during processing than rice. In India, the bulk of wheat is consumed as whole grain wheat flour or atta. Madhy ev white flour which represents 70 per cent extraction of wheat is poorer from the nutrition standpoint. The yellow variety of wheat the greater the loss of vitamins and minerals. Thus whole grain wheat flour is richer source of vitamin B than refined white flour.

**Maize**

Maize (Corn, bhutta) ranks next to rice and wheat in world consumption, and in certain areas it is the principal source of proteins and energy both. It is also used as a food for cattle and poultry. The yellow variety of maize contains significant amount of caroteneoid pigments. Maize is fairly rich in fat (Table 10). The proteins of maize are deficient in tryptophan and lysine; and some strains contain an excess of leucine. Studies indicate that excess of leucine interferes in the conversion of tryptophan into niacin, and thus aggravates the pellagraic action of maize. Maize is also used in the manufacture of breakfast foods such as cornflakes. Maize flour or corn flour is widely used in the preparation of custards and table desserts. The incorporation of opaque-2 gene into maize has greatly improved the quality of its protein.

**MILLETs**

The term “millet” is used for smaller grains which are grown and eaten without having the outer layer removed; they are jowar (sorghum), bajra (pearl millet), ragi, koabo and a few others known as “minor millets” or pseudocereals (70). The nutritive value of millets is as shown in Table 18.

Source: (34)

**Jowar (sorghum)**

Jowar is also known as kafir corn or Milo. It is a major crop grown in India next only to wheat and rice. For several population groups, it is a staple diet. The protein content of jowar varies from 9 to 14 per cent, and the proteins are limiting in lysine and threonine. Certain varieties of jowar have a high leucine content and consumption of these varieties is associated with pellagra. This disorder is often seen in the Telengana and Marathwada regions where jowar is predominantly consumed.

**Bajra (pearl millet)**

Bajra is grown extensively in the dry belts of northern and peninsular India, viz. Rajasthan, Gujarat and Maharashtra, where it forms the staple food of large sections of the population. The protein content varies from 20 to 25 per cent and the proteins are deficient in lysine and threonine.

**Ragi**

Ragi is a popular millet in Andhra and Karnataka. It is the cheapest among millets. Ragi flour is cooked and eaten as porridge. Ragi is rich in calcium (see Table 18).

**2. Pulses (legumes)**

Pulses comprise a variety of grains, also known as dals. Most commonly eaten pulses are bengal gram (chana), red gram (tuvar or arhar), green gram (mung) and black gram (urd). Others include lentils (masur), peas and beans including soyabean, Rhesus dhal (Lathyrus sativus), is consumed in parts of Madhya Pradesh, Uttar Pradesh and Bihar excessive consumption of which is associated with laxirhythm.

Pulses contain 20 to 25 per cent of proteins, which is double that found in wheat and three times that found in rice. In fact, pulses contain more protein than eggs, fish or flesh foods. But it is a quality protein, pulse proteins are inferior to animal proteins. Pulse proteins are poor in methionine and to a lesser extent in cysteine. On the other hand they are rich in lysine. Soyabean is exceptionally rich in protein, containing up to 40 per cent. In addition, pulses are rich in minerals and B-group vitamins such as riboflavin and thiamine. In the dry state, pulses do not contain vitamin C. Germinating pulses, however, contain higher concentration of vitamins, especially vitamin C and B vitamins. Fermentation also modifies the nutritive value of pulses in that the vitamin content particularly that of riboflavin, thiamine and niacin is enhanced.

Although pulses are called “poor man’s meat”, they are eaten by the rich and poor alike in India. They give variety to the diet and make the food more palatable. Table 19 gives the nutritive value of pulses and their common pulses.

**Anti-nutritional factors**: In the raw state, pulses have some anti-nutritional factors such as phytates and tannins which adversely affect the availability of some nutrients to the body. However, most of the anti-nutritional factors are destroyed by heat. Presence of high amounts of certain sugars known as glycosaccharides is known to be associated with flatulence (71).

**Soyabean**

Soyabean is the richest among pulses. It contains about 40 per cent of protein, 20 per cent of fat and 4 per cent of minerals. The protein of soyabean are of relatively high nutritive value. The limiting amino-acid is methionine. Soyabean can be cooked and eaten as dhal. It can be tried in other forms like mixing its powder with atta for chapattis, soyabean milk and curd and in baby foods. Soyabean is yet to become popular in India despite many years of publicity.

3. Vegetables

Vegetables are classified as "protective foods"; their value resides in their high vitamin and mineral content. Some vegetables (e.g., green peas, beans) are also good source of protein. Vegetables usually have a large water content, low energy and protein content and varying amounts of "dietary fibre". Vegetables are divided into three groups "green leaves", "roots and tubers", and "others".

a. Green leaves

The term "green leaves" designates a number of indigenous leafy vegetables consumed by the people. They include palak (spinach), amaranth, ebbobage, fenugreek (methi) etc. The dower the green leaves, the greater their nutritive value. With the possible exception of vitamin B12, green leaves are rich sources of carotenoids, calcium, iron and vitamin C. They are also fairly good sources of riboflavins, folic acid and many other micronutrients. In addition, leaf proteins (2 to 4 per cent) are good sources of lysine, although deficient in sulphur — containing amino acids. The bioavailability of calcium and iron from greens is rather poor because of the presence of high amounts of oxalates. Leafy vegetables are high in water content and dietary fibre. Because of their low coliacal value (25 to 50 kcal per 100 g)
and large bulk, they have an important place in the dietaries of obese people who wish to cut down their calorie intake. The recommended daily intake of green leafy vegetables is about 45g for an adult.

b. Roots and tubers

Included in this group are potato, sweet potato, tapioca, yam, carrots, onion, radish and colacasia. They vary widely in composition, some are good sources of carbohydrates such as potatoes and tapioca. In general roots and tubers are poor in protein, minerals and vitamins. Carrots are exceptionally high in betacarotene. In times of cereal shortage, potatoes, sweet potatoes, and yam can serve as subsidiary foods for limited periods. But bulk and low protein make them unsuitable as staple foods for longer periods, unless supplemented by foods richer in proteins. The recommended daily intake of roots and tubers is 50 to 60 g for an adult.

c. Other vegetables

There is a wide range of “other” vegetables such as brinjal, tomatoes, cauliflower, etc. They bring variety to the diet. Many of them are fairly good sources of minerals and vitamins. Some vegetables like cluster beans, drumsticks and green mango contain fair amounts of iron. The daily recommended intake is 60 to 70 grams.

4. Nuts and oilseeds

Belonged in this group are groundnuts (Peanut), cashewnut, coconut, walnut, almonds, pistachio, mustard seeds, sesame seeds, cotton seeds, sunflower seeds, maize germ and many others from which cooking oils are extracted.

Nuts and oilseeds contain good amount of fat and good quality protein in a relatively small bulk. Regarding the fat content, walnuts contain 64.5 per cent, almonds 58.7 per cent, cashewnuts 46.9 per cent and groundnut 40 per cent. Peanut (groundnut) butter is a very popular article of the diet. Regarding protein content, groundnut tops the list with 26.7 per cent. Being of vegetable origin, their protein is not equal to that of meat or eggs in quality. Nuts are good sources of vitamins of the B-group. They contribute minerals such as calcium, phosphorus, and iron. Among the commonly used nuts, cashewnuts and almonds are good sources of iron, but pistachio is the richest containing 14 mg of iron per 100 g.

Most of the vegetable oils are rich in essential fatty acids. After oil extraction in the case of some, the residue (oilseed cake) can be formulated into acceptable foods rich in protein. For example, groundnut flour is used in the manufacture of Indian Multipurpose Food, balahar and balanced mill food. Due partly to their high fat content and partly to their high cellulose content, nuts are not easily digestible. However, nuts eaten in a mixed diet are an extremely valuable source of protein. Peanuts for human consumption should be thoroughly dried and properly stored to avoid the growth of Aspergillus flavus which produces “ aflatoxin”.

5. Fruits

Fruits are protective foods. They are invaluable in human nutrition because they are good sources of vitamins and minerals. One special feature which distinguishes fruits from other foods is that they can be eaten raw and fresh. This makes the vitamins and minerals present in fruit easily available.

Nutritive value

(1) Vitamins: Fruits are prized for their vitamins. Most fruits contain significant amounts of ascorbic acid. The orange, guava and the Indian blackberry (amla) are particularly rich in ascorbic acid. One medium sized orange can provide enough juice to meet the daily requirement of ascorbic acid of an adult. Apart from ascorbic acid, several fruits contain good amounts of carotene. The papaya and mango are excellent sources of carotene. (2) Minerals: Fruits are good sources of minerals especially sodium and potassium. Some fruits like safalha (custard apple) are rich in calcium. Dried fruits like raisins, dates and apricots are good sources of calcium and iron. Fruits also contain a great variety of organic acids which are responsible for the sources of urine fruits. The intake of fruits leads to an alkaline urine. (3) Carbohydrates: Fruits in general have a low energy value but some fruits like banana and mango contain good amounts of carbohydrate and can act as good source of energy. Pectin, a kind of sugar, present in fruits like guavas is helpful in the preparation of fruit jelly. The fruit sugars are easily digestible and completely absorbed. The more ripe a fruit is, the higher its sugar content. (4) Cellulose: Fruits contain cellulose which assists in normal bowel movements.

Nutrition experts recommend a daily intake of 85 grams or more of fresh fruit for maintenance of good health. Fruits are costly and it may not be within the reach of all to afford them daily. If green leafy vegetables are included in the daily diet, the need for fruit as an essential item in the diet is much reduced. The aim in nutrition education should be to promote the intake of seasonal fruits which are cheaper and fresher. The only fruits are not necessarily the best in respect of nutrients. The food values of some common fruits are as given in Table 20.

6. Animal foods

Foods of animal origin include meat, poultry, fish, eggs, milk and dairy products. They provide high quality protein (combining all the essential amino acids) and good amounts of fat, besides some vitamins and minerals. Vitamin B12 is one of the rare nutrients found only in animal foods. Since they are expensive, animal foods are consumed in small quantities.
natural milk and "made-up" milk. It contains 1 part of water 1 part of natural milk and 1/8 part of skim milk powder. The mixture is stirred, pasteurized and supplied in bottles. Toned milk has a raw egg white as a colorant to cow's milk; it is cheaper and yet a wholesome product.

Vegetable milk
Milk prepared from certain vegetable foods (viz. groundnut, soyabean) is termed "vegetable milk". It may be better for the health in some respects. Vegetable milk consists of:

(i) Proteins: The chief protein of milk is casein; it occurs in combination with calcium as calcium caseinate. The other proteins are lactalbumin and lactoglobulin. Animal milk contains nearly three times as much protein as human milk. Milk proteins contain all the essential amino acids.

(ii) Minerals: The content of milk varies from 3.4 per cent in human milk to 8.8 per cent in buffalo milk. Human milk contains a higher percentage of linoleic acid and oleic acid than animal milks. Milk fat is a good source of retinol and vitamin D. (iii) Sugar: The carbohydrate in all milks is lactose or milk sugar. It is found nowhere else in nature. It is less sweet than cane sugar and is readily fermented by lactic acid bacteria. Human milk contains more sugar than animal milks. (iv) Vitamins: Milk contains all known minerals needed by the body; such as calcium, phosphorus, sodium, potassium, magnesium, cobalt, copper, iodine, etc. Milk is particularly rich in calcium; it is however a poor source of iron. (v) Vitamins: Milk is a good source of all vitamins except vitamin C.

I. Human and animal milks are as compared in Table 21, which illustrates that milk is a good extant species-specific.

Milk products
Milk is consumed in a variety of forms - as whole milk, butter, cheese, dried and condensed milk, those, ice cream, etc. Milk from which fat has been removed is known as "skimmed milk." It is devoid of fat and fat soluble vitamins, but is a good source of milk protein (35 per cent) and lactose.

Toned milk
The term "toned" is an Indian coinage. It is a blend of
meat contains varying amounts of fat, which is composed of non-essential saturated fat. The energy provided by meat depends upon its fat content. Besides iron, meat provides minerals such as zinc and B-vitamins. It is poor in calcium (10 to 25 mg per 100 g) but rich in phosphorus. Liver is extremely rich in many nutrients.

Table 22 shows the nutritive value of meat, fish and eggs.

7. Fats and oils

Good cooking demands liberal use of oils and fats. Fats which are liquid at room temperature are called oils. Fats and oils are good sources of energy and fat-soluble vitamins. Fats of animal origin are poor sources of essential fatty acids. Those of vegetable origin are rich in poly-unsaturated fatty acids, excepting coconut and palm oils. The vegetable oils contain no vitamin A and E, except for red palm oil which is extremely rich in carotene. During the past 20 years, there has been a great increase in manufacture of vanaspati (hydrogenated fat) under various trade names. Margarine is made from vegetable oils and is fortified with vitamin A and D.

8. Sugar and jaggery

These are carbohydrate foods. Sugar is produced from sugarcane in India, and from sugar beet elsewhere. Refined sugar is pure sucrose and contains no other nutrients. Jaggery is prepared from sugarcane in India and is consumed in place of sugar. It contains useful amounts of carotene and iron derived from cooking pans. Honey consists of about 75 per cent sugars, mostly fructose and glucose.

9. Condiments and spices

These include asafetida, cardamom, chilies, garlic, cloves, ginger, mustard, pepper, tamarind, turmeric, etc. They are mainly used to enhance the palatability of foods and stimulate appetite. The essential oils present in them have carminative properties and may aid in digestion. Excessive consumption of condiments is associated with 'peptic ulcer.'

10. Miscellaneous

Beverages: Diet includes beverages, and especially water which is essential to life. Beverages include drinks which are appreciated for their flavour or their stimulating properties. They may be classified as follows:

(i) Coffee, tea, cocoa.

(ii) Soft drinks: aerated water, lemonade, pepti cola, fruit juices, etc.

(iii) Alcoholic beverages: wine, beer, whisky and traditional preparations. Alcoholic beverages are rich in calories.

Coffee, tea and cocoa

(a) Coffee: Coffee contains caffeine (0.6 to 2.0 per cent), volatile oils (caffoil) and tannic acid. Caffeine is a stimulant of the nervous system. When coffee seeds are roasted, tannin is destroyed, proteins are coagulated and the pleasant aroma is liberated.

(b) Tea: These are two main varieties of tea – the green and the black varieties. Green tea which is morestringent than the black variety is popular in China, Japan and Assam. The chemical composition of tea is as follows: (i) caffeine: 2 to 6 per cent (ii) tannic acid: 6 to 15 per cent (iii) theophylline: traces (iv) essential volatile oils: 5 per cent. Tea is prepared by adding leaves to boiling water. When milk is added, the casein of milk combines with tannin and forms a harmless complex.

(c) Cocoa: Cocoa is obtained from cocoa beans. It is rich in fat, and contains theobromine which has stimulating properties. The composition of a cup of tea, coffee and cocoa containing the usual amount of sugar is given in Table 23. The nutritive value of a cup of tea or coffee is really due to its milk and sugar content.

Table 23

| The chemical composition of coffee, tea and cocoa (values per cup of 150 ml) |
|-------------------------------------------------|----------|-----|-----|
| Protein (g)                                     | 1.8      | 0.9 | 7.2 |
| Fat (g)                                         | 2.2      | 1.1 | 8.8 |
| Carbohydrate (g)                                | 17.8     | 16.4| 26.2|
| kcal                                           | 98.0     | 79.0| 213.0|

Soft drinks

Some are carbonated (e.g., soda water incorporating carbon dioxide under high pressure) and others non-carbonated such as fruit juices. The principal ingredients of soft drinks are carbon dioxide, sugars, acids such as citric acid or tartaric acid, colouring and flavouring agents. Fruit beverages comprise fruit juices, squashes and cordials. Fruit squashes and cordials are diluted with water before consumption.

Alcoholic beverages

These are beer, whisky, rum, gin, arrack, etc. The alcoholic content of these beverages varies widely from 5 to 6 per cent in beers to 40 to 45 per cent in whisky, rum, gin and brandy. Alcohol supplies about 7 kcal per gram.

b. Vinegar

Natural vinegar is made from fermentation of fruits, malt and molasses. It contains a minimum of 3.7 per cent acetic acid. Synthetic vinegar should not be harmful if it is free from lead, copper, arsenic or mineral acids. Synthetic vinegar should be distinctly labelled "SYNTHETIC" according to Prevention of Food Adulteration Act rules.

NUTRITIONAL REQUIREMENTS

Basic concepts

The science of human nutrition is mainly concerned with defining the nutritional requirements for the promotion, protection and maintenance of health in all groups of the population. Such knowledge is necessary in order to assess the nutritional adequacy of diets for growth of infants,
children and adolescents, and for maintenance of health in adults of both sexes and during pregnancy and lactation in women (85). In this context, a variety of terms have been used to define the amount of nutrients needed by the body such as: "optimum requirements," "minimum requirements," "recommended intakes" or "allowances," and "safe level of intake." Of these, the term "recommended dietary intake or allowance" (RDA) has been widely accepted (1).

Recommended dietary allowance (RDA) : The average daily dietary nutrient intake level sufficient to meet the nutrient requirement of nearly all (97-98 per cent) healthy individuals in a particular life stage and gender group (9).

Adequate Intake : A recommended average daily intake level based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of apparently healthy people, that are assumed to be adequate - used when an RDA cannot be determined. In the Indian context, this is referred to as "acceptable intake" (9).

Tolerable upper intake level (UL) : The highest average daily nutrient intake level that is likely to pose no risk of adverse health effects for almost all individuals in the general population. As intake increases above the UL, the potential risk of adverse effects increases (9).

Estimated average requirement (EAR) : The average daily nutrient intake level estimated to meet the requirement of half of the healthy individuals in a particular life stage and gender group (9).

The RDA is derived from (a) the individual variability; and (b) the adequacy factor. Individual variability : Definition of RDA takes into account the variability that exist in the requirement of a given nutrient between individuals in a given population group. The distribution of nutrient requirement in a population group is considered normal when the RDA corresponds to a requirement, which covers most of the individuals (97.5 per cent) in a given population. This corresponds to mean + 2 SD. This is termed as a safe level of nutrition, the chances of individual having requirements above the RDA is only 2.5 per cent. This principle is used in case of all nutrients except energy. In case of energy, intakes either in excess or below the actual requirement of energy are not safe. In respect to other nutrients, the RDA is 25 per cent (± 2 SD) higher than the mean requirement, 12.5 per cent being considered as the extent of individual variability in the requirement of all those nutrients (9).

Bioavailability : Bioavailability of a given nutrient from a diet, i.e., the release of the nutrient from the food, its absorption in the intestine and bioreponse to be taken into account. It is the level of the nutrient that should be present in the diet to meet the requirement. The bioavailability of other nutrients in the diet is present in the diet to be 20-30 times higher than that in the usual diet. Thus, it is the level of the nutrient that should be present in the diet to meet the requirement. Bioavailability of a given nutrient from a diet, particularly a cereal-based diet.

RDA presents the level of the nutrient to be consumed daily to meet all requirements of most of the individuals in a given population. However, it must be recognized that the RDA is not meant to be used as a standard to determine whether or not a given individual requirement has been met, since it is a level above the requirement of most individuals in a given population. RDA values of the nutrient is valid only when all other dietary nutrient intakes are satisfactory.

**REFERENCE BODY WEIGHTS (9)**

Age, gender and body weight largely determine the nutritional requirement of an individual. Body weights and heights of children reflect their state of health, nutrition and growth status, while weight and heights of adults represent what can be attained by an individual with normal growth. Anthropometric measurements of infants and children of 6-12 months of age and adults are easily measured and nutritional standards are usually treated as reference values. The purpose of recommending nutrient requirements is to help attain these anthropometric reference standards.

**WHO standard weights and heights of infants and pre-school children**

World Health Organization has recently published multi-centre growth reference standards for 0-60 month boys and girls, based on studies carried out among predominately exclusively breast-fed children in six countries viz. USA, Brazil, Ghana, Norway, Oman and India. The median weights of infants and pre-school children (1-3 years) can be taken as reference values for Indian children.

**Reference Indian adult man and woman**

"Reference man" is aged between 18-29 years and weighs 60 kg with a height of 1.73 metre and a BMI of 20.3; is free from disease and physically fit for active work. On each working day, he is engaged in 6 hours of occupation which usually involves moderate activity, while while not at work he spends 8 hours in bed, 4-6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

"Reference woman" is aged between 18-29 years, non-pregnant non-lactating (NPNL) and weighs 55 kg with a height of 1.63 metre and a BMI of 21.2, is free from disease and physically fit for active work. On each working day, she is engaged in 6 hours of occupation, which usually involves moderate activity, while while not at work she spends 8 hours in bed, 4-6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

**Infants**

The average of birth weight and body weight at 6 months is used for computing the reference body weight for infants of all ages of age. For 6-12 months, the average of body weight at 6 months and at 12 months is taken for computation.

**Children**

For children, 1-3 years of age, an average of body weight at 18 months, 20 months, 42 months of WHO median weight is taken (as mentioned above).

The reference body weight for children of 4-6 years are obtained by averaging the body weight of 4a, 5a and 6a years. Similarly for older children also the reference body weights were obtained from the 95th centile value of body weights of rural India.

**Adults**

The average of values for age category of 18-19, 20-24, and 25-29 years was used for computing the reference weights for adult man and woman.
ENERGY

Energy is a prime requisite for body function and growth. When a child’s intake of food falls below a standard reference, growth slows, and if low levels of intake persist, adult stature will be reduced. Similarly, if adults fail to meet their food requirements, they lose weight. This may lead to reduced ability to work, to resist infection, and weakened will to enjoy the normal satisfaction of life. This underlines the need for an adequate intake of food which is the source of all energy.

Measurement of energy

The energy value of foods has long been expressed in terms of the kilocalorie (kcal). The kilocalorie is generally expressed as “Calorie”—written with a capital “C” (74). This has been replaced by the “Joule” expressed as J, which has been accepted internationally. These units are defined as follows:

Joule, a physical unit of energy, is defined as the energy required to move 1 kg of mass by 1 metre by a force of 1 Newton acting on it (One Newton is the force needed to accelerate one kg mass by 1 metre per sec²).

Kilojoule (kcal) is defined as the heat required to raise the temperature of one kg of water by 1°C from 14.5°C to 15.5°C. The unit kcal is still popularly used.

The relationship between the two units of energy is as follows:

1 kcal = 4.184 kJ (Kilo Joule)
1 KJ = 0.239 kcal
1000 kcal = 4184 KJ (Mega Joule)
1 MJ = 239 kcal

Reference men and woman

Energy intake recommendations are formulated for a “reference man” and a “reference woman” whose profiles are described, and then necessary adjustments are made for subjects who deviate from the standard reference. This procedure was first devised by the FAO Committee on calorie requirements in 1950 (75) and has been in use ever since.

Energy requirements

The energy requirement of an individual is defined as the level of energy intake from food that balances energy expenditure, when the individual has a body size and composition and level of physical activity, consistent with long-term good health, also allowing for maintenance of economically essential and socially desirable activity. In children and pregnant and lactating women, it includes the energy needs associated with the deposition of tissues or secretion of milk at rates consistent with good health (9). The two standard deviation value is not added to the average requirement. This is because the energy intake and expenditure of an individual are finely balanced, and any surplus energy consumption will be stored as fat and a continuous excess of intake will lead to obesity (9). Adults and even growing children are known to adapt either intake to suit their output, or output to suit intake over a very wide range. We do not have a proper understanding of the lower limit of adaptation.

Broadly, the total energy requirement of an individual is made up of three components:

(a) energy required for basal metabolism. This is about 1 kcal/hour for every kg of body weight for an adult;
(b) energy required for daily activities such as waking, sitting, standing, dressing, climbing stairs, etc.
(c) energy expenditure for occupational work. This is further classified as light work (an office clerk), moderate work and heavy work (manual physical labour).

The first component is nearly the same for all individuals. It is the faster components that vary depending upon the type of activities. Procedures for calculating total energy expenditure are given in the WHO Expert Committee Report on Energy and Protein Requirements (6).

Factors affecting energy requirements

Energy requirements vary from one person to another depending upon inter-related variables acting in a complex way, such as age, sex, working condition, body composition, physical activity, physiological state etc. All these factors lead to differences in food intake.

Energy requirements have been laid down by various expert groups of FAO and WHO. (6, 38, 76). It has become customary for countries to lay down their own standards. Thus there are British standards, American standards, Canadian standards, etc. The standards in India are those recommended by the Indian Council of Medical Research which are set out in Table 24. These standards are revised from time to time in the light of newer knowledge.

Vulnerable groups

(a) Pregnant and lactating mothers: The energy requirements of women are increased by pregnancy (+350 kcal daily throughout pregnancy) and lactation (+600 kcal daily during the first 6 months, and +200 kcal daily during the next 6 months) over and above their normal requirements. This is to provide for the extra energy needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health (6).

(b) Children: Because of their rapid growth rate, young children require proportionately more energy for each kilogram of body weight than adults (see Table 25).

A problem that arises is in recommending intakes in communities where a large number of children are underweight because of malnutrition. In order to provide for “catch-up growth” during childhood, intakes should be based on age rather than weight where practical (77). The ICMR standards are based on age, and not on body weight (except during the first year of life).

Children above the age of 13 years need as much energy as adults. This is because they show a good deal of physical activity, almost equal to hard work by adults. This also the age when puberty sets in and there is a spurt in growth and an increase in metabolic rate. This fact should be borne in mind when planning diets for children.

(c) Adults: The energy requirements decrease with age because of a fall in BMR and a decrease in physical activity in most persons. In general, there is a 2 per cent decline of resting metabolism for each decade for adults (31). The FAO/WHO committee suggested that after the age of 40 years, requirements should be reduced by 5 per cent per each decade until the age of 60, and by 10 per cent for each decade thereafter (76).

### Source of energy

The main source of energy in Indian diets, which are predominantly plant food based, are carbohydrate, fat, protein and dietary fibre. They supply energy at the following rates:

- **Protein**: 4 kcal/g
- **Fat**: 9 kcal/g
- **Carbohydrate**: 4 kcal/g
- **Dietary fibre**: 2 kcal/g

Dietary fibre forms an indigestible and important component of plant food and was never earlier considered as source of energy. These dietary fibres (soluble and insoluble) undergo fermentation in the colon and yield short chain fatty acids, such as butyric, propionic and acetate acids which are utilized as a source of energy by the colon cells and by the liver. Hence they are known to yield energy from fermentable fibre and no energy from non-fermentable fibre. In conventional foods, 70 per cent of fibre is fermentable. In general, energy conversion factor for fibre is taken as 2.0 kcal/g. Hitherto, dietary fibre was not determined directly as a source of energy and there is a need to re-calculate energy yield of various foods on the basis of their revised content of carbohydrates, proteins, fat and dietary fibre (9).

The main source of energy in diets is carbohydrates derived largely from cereals. These cereals constitute about 80 per cent of our diet and provide 50-80 per cent of daily energy intake. However, energy contribution from diets varies very widely. Those belonging to low income group have only 5 per cent fat in their diet, whereas affluent families derive as high as 30 per cent of their dietary energy from fat. Most families derive 10-12 per cent of energy from proteins (9).

### Nutritional individuality

In norms individual at all ages and of both sexes, there is a large vacation in energy intake but the reasons for this wide range of nutritional requirements are not known. The concept of nutritional individuality needs to be stressed, and its neglect may result in the underfeeding of some whose needs happen to be less than the "average standard requirement" (78).

### PROTEIN

Protein requirements vary from individual to individual. Apart from age, sex and other physiological variables, factors like infection, wound inflammation, emotional disturbances and stress situations can affect a person's protein requirement.

#### Assessment of protein

**(a) PROTEIN QUALITY**

The quality of a protein is assessed by comparison to the "reference protein" which is usually egg protein. Two methods of assessment of protein quality need mention:

1. **(i) Amino acid score**: It is a measure of the concentration of each essential amino acid in the test protein expressed as a percentage of that amino acid in the reference protein.

   - Amino acid score = mg of amino acid per g of test protein × 100
   - mg of the same amino acid per g of reference protein.

   The amino acid (or chemical) score is somewhere between 50 and 60 for starches, and 70 and 80 for animal foods (69).

2. **(ii) Protein utilization (NPU)**: It is a product of digestibility coefficient and biological value divided by 100 (8). The NPU gives a more complete expression of protein quality than the amino acid score. It is a biological method that requires special laboratory facilities.

   - NPU = Nitrogen retained by the body × 100
   - Nitrogen intake

In calculating protein quality, 1 gram of protein is assumed to be equivalent to 6.25 g of N.

The protein requirement varies with the NPU of dietary protein. If the NPU is low, the protein requirement is high and vice versa. The NPU of the protein of Indian diets varies between 50 and 80.

#### (b) PROTEIN QUANTITY

The protein content of many Indian foods has been determined and published in food composition tables. One way of evaluating foods as a source of protein is to determine what per cent of their energy value is supplied by their protein content. This is known as Protein–Energy Ratio (PE ratio or percentage).

- PE per cent = Energy from protein × 100
- Total energy in diet

This concept is useful because in many population groups adequate diet is not consumed to meet energy needs, resulting in energy deficits. The ratio of protein requirement,
expressed as the ratio of protein calories to the energy requirement is as given in Table 25.

<td>3</td>
</tr>
</tbody>
</table>

If the PE is less than 4 per cent, the subject will be unable to eat enough to satisfy protein requirements. It is recommended that protein should account for approximately 10-12 per cent of the total daily energy intake.

### Dietary intakes

It is customary to express requirement in terms of grams per kg of body weight. This principle applies to all age groups, although absolute additions in units of grams of protein per day are made for pregnancy and lactation.

The ICMR Expert Group (9) suggested an intake of one gram of protein per kg of body weight for adult males and females, assuming a NPU of 65 for the dietary protein. Table 29 gives the protein intakes for individuals of different ages and physiological states.

### Vulnerable groups

The protein requirements of women are increased during pregnancy. For 10 kg gestational weight gain the requirement increases by 1, 7 and 23 g/day in 1st, 2nd and 3rd trimesters respectively; and during lactation by about 13 g per day (during 0 to 6 months), over and above their normal requirements.

Young children (0 to 5 years) require proportionately more protein for each kilogram of body weight than adults. They are more vulnerable to malnutrition.

The ICMR Expert Group (9) has not made any recommendations for the elderly. It seems reasonable to assume that the requirement of the aged are not less than that for young adults, because it is an accepted fact that protein utilization is less efficient in the elderly (6).

All estimates of protein requirement are valid only when the energy requirements are fully met. If the total energy intake is inadequate some dietary protein will be diverted to provide energy. It is now accepted that there are no body protein stores which can be filled up by a high protein intake.

At present there is no evidence that higher intakes of protein confer greater benefit, although the possibility cannot be ruled out. Most people, if they can, apparently choose to eat more protein than the physiological requirement. The question remains whether high protein intakes, far from being beneficial, may actually be harmful (7).

### Amino acid requirements

The protein intake must also satisfy the need for essential amino acids. The 2007 WHO Expert Committee Report on Energy and Protein Requirements gives current estimates of amino acid requirements (in mg/kg per day) for adults. These are reproduced in Table 27.

</tr>
</tbody>
</table>

Source: (9)

New tissues cannot be formed unless all the essential amino acids are present in the diet. The requirement of EAA decreases sharply as one advances in age. The quality of the diet is far more critical for the infant than for the adult.

### FAT

The daily requirement of fat is not known with certainty. During infancy, fats contribute to a little over 50 per cent of the total energy intake. This scales down to about 20 per cent in adulthood. The ICMR Expert Group (2010) has recommended an intake of 20 per cent of the total energy intake as fat, of which at least 50 per cent of fat intake should consist of
vegetable oils rich in essential fatty acids. The requirement of essential fatty acids ranges from 3 per cent energy intake to 5.7 per cent of energy intake in young children.

Suggested levels of fat intake are as given in Table 28.

### CARBOHYDRATE

The recommended intake of carbohydrate in balanced diets is placed so as to contribute between 50 to 80 per cent of total energy intake. Most Indian diets contain amounts more than this, providing as much as 90 per cent of total energy intake in some cases, which makes the diet imbalanced. This needs to be corrected through nutrition education.

The recommended dietary allowances for energy, protein, fat, and minerals is summarized in Table 29.

### OTHER RECOMMENDED INTAKES

(a) **Fat soluble vitamins**

The daily requirement of vitamins A is given in Table 30. The recommended dietary allowance of vitamin E is placed at 10 mg of alpha tocopherol equivalents for adult males and 8 mg for adult females.

(b) **Water soluble vitamins**

The recommended intakes are given in Table 30. The requirements of thiamine, riboflavin and niacin are closely related to energy intake and utilization, and are stated in terms of 1000 kcal intake of energy as below:

- Thiamine: 0.5 mg/kcal
- Riboflavin: 0.6 mg/kcal
- Niacin: 6.0 mg/kcal

(c) **Minerals**

The recommended intakes of important minerals are as given in Table 29.

Source: (9)

At nutritional requirements are interrelated. For example, there is a close interrelationship between the energy and protein requirements, between requirements for phosphorus, calcium and vitamin D, between fats and vitamins, and between carbohydrates and vitamins.

It has been said that food is not only a collection of nutrients open to statistical or dietary study, but also simultaneously a system of communication, a protocol for customs, situations and behaviour.

**BALANCED DIET**

A diet may be defined as the kinds of food on which a person or group lives. A balanced diet is defined as one which contains a variety of foods in such quantities and proportions that the need for energy, amino acids, vitamins, minerals, fats, carbohydrate and other nutrients is adequately met for maintaining health, vitality and general well-being and also makes a small provision for extra nutrients to withstand short duration of leanness (629). A balanced diet has become an accepted means to safeguard a population from nutritional deficiencies (79).

In constructing balanced diet, the following principles should be borne in mind: (a) First and foremost, the daily requirement of protein should be met. Take amounts to 10-15 per cent of the daily energy intake. (b) Next comes the fat requirement, which should be limited to 15-30 per cent of the daily energy intake. (c) Carbohydrates rich in natural fibre should constitute the remaining food energy. The requirements of micronutrients (Table 29 and 30) should be met.

The dietary pattern varies widely in different parts of the world. It is generally developed around the kinds of food produced (or imported) depending upon the climatic conditions of the region, economic capacity, religion, customs, taboos, tastes and habits of the people. Balanced diets formulated by the Indian Council of Medical Research are given in Annexure II at the end of this chapter.

A nutritional education guide "The Food Guide Pyramid" emphasizes foods from the five major food groups shown in the three lower sections of the Pyramid (Fig. 1). Each of these food groups provides some, but not all, of the nutrients required. Foods in one group can't replace those in another. No one of these major food groups is more important than another – for good health, one needs them all.

**DIETARY GOALS**

All countries should develop a national nutrition and food policy setting out "dietary goals" for achievement (72). The dietary goals ("prudent diet") recommended by the various Expert Committees of WHO (15,79) are as below:

(a) dietary fat should be limited to approximately 15-30 per cent of total daily intake;

(b) saturated fats should contribute no more than 10 per cent of the total energy intake; unsaturated vegetable oils should be substituted for the remaining fat requirement;

(c) excessive consumption of refined carbohydrate should be avoided; some amount of carbohydrate rich in natural fibre should be taken;

(d) sources rich in energy such as fats and alcohol should be restricted;

(e) salt intake should be reduced to an average of not more than 5 g per day; (salt intake is more in tropical countries. In India it averages 15 g per day);
(f) protein should account for approximately 10–15 per cent of the daily intake.
(g) junk foods such as cakes, ketchups and other foods that supply empty calories should be reduced.

There may be conditions under which the above recommendations for daily food intake do not apply. For example, diet should be adapted to the special needs of growth, pregnancy, lactation, physical activity, and medical disorders (e.g., diabetes).

NUTRITIONAL PROBLEMS IN PUBLIC HEALTH

There are many nutritional problems which affect vast segments of our population. The major ones which deserve special mention are highlighted:

1. Low birth weight

Low birth weight (i.e., birth weight less than 2500 g) is a major public health problem in many developing countries. About 28 per cent of babies born in India are LBW (81) as compared to 4 per cent in some developed countries. In countries where the proportion of LBW infants is low, most of them are preterm (82). Although we do not know all the causes of LBW, maternal malnutrition and anemia appear to be significant risk factors in its occurrence. Among the other causes of LBW are hard physical labour during pregnancy, and illnesses especially infections. Short maternal stature, very young age, high parity, smoking, close birth intervals are all associated factors. All these factors are interrelated.

Since the problem is multifactorial, there is no universal solution. Interventions have to be cause-specific. This matter has already been discussed in Chapter 9.

The proportion of infants born with LBW was selected as one of the nutritional indicators for monitoring progress towards Health for All by the year 2000.

2. Protein energy malnutrition

Protein energy malnutrition (PEM) is identified as a major health and nutrition problem in India. It occurs particularly in weaklings and children in the first years of life. It is not only an important cause of childhood morbidity and mortality, but leads also to permanent impairment of physical and possibly, of mental growth of those who survive (9). The current concept of PEM is that it is a clinical forms — kwashiorkor and marasmus — are two different clinical pictures at opposite poles of a single continuum.

The incidence of PEM in India in pre-school age children is 1–2 per cent (83). The great majority of cases of PEM, nearly 80 per cent, are the "intermediate" ones, that is the mild and moderate cases which frequently go unrecognized. The problem exists in all the States and that nutritional anæmia is more frequent than kwashiorkor.

In the 1970s, it was widely held that PEM was due to protein deficiency. Over the years, the concept of "protein gap" has given place to the concept of "food gap". That is, PEM is primarily due to (a) an inadequate intake of food (food gap) both in quantity and quality, and (b) infections, notably diarrhea, respiratory infections, measles and intestinal worms which increase requirements for calories, protein and other nutrients, while decreasing their absorption and utilization. It is a vicious circle — infection contributing to malnutrition and malnutrition contributing to infection, both acting synergistically (Fig. 2).
There are numerous other contributory factors in the web of causation, viz. poor environmental conditions, large family size, poor maternal health, failure of lactation, premature termination of breast-feeding, and adverse cultural practices relating to child rearing and weaning such as the use of over-diluted cow's milk and discarding cooking water from cereals and delayed supplementary feeding (64).

Malnutrition is self-perpetuating. A child's nutritional status at any point of time depends on his or her past nutritional history, which may particularly account for the present status. To some extent, this nutritional history is linked to the mother's health and nutritional status. This in turn has been influenced by her living conditions and nutritional history during her own childhood (Fig. 3).

CLASSIFICATION OF PEM

PEM is a spectrum of conditions ranging from growth failure to overt marasmus or kwashiorkor, hence classification has to be based on arbitrary cut-off points. It is to identify children requiring nutritional or health interventions. Some of the classifications are as follows:

Gomez' classification (68)

Gomez' classification is based on weight retardation. It locates the child on the basis of his or her weight in comparison with a normal child of the same age. In this system, the "normal" reference child is in the 50th centile of the Boston standards. The cut-off values were set during a study of risk of death based on weight for age at admission to a hospital unit. This classification therefore, has a pragmatic value for hospitalized children.

Weight for age (%): weight of the child / weight of a normal child of same age x 100

| Between 90 and 110% | Normal nutritional status |
| Between 75 and 83% | 1st degree, mild malnutrition |
| Between 60 and 74% | 2nd degree, moderate malnutrition |
| Under 60% | 3rd degree, severe malnutrition |

Weight is widely recorded and the classification is easy to compute. The disadvantages are (a) A cut-off point of 90 per cent of reference is high (80 per cent being approximately equivalent to -2SD or the 3rd percentile), thus some normal children may be classified as 1st degree malnourished. (b) By measuring only weight for age it is difficult to know if the low weight is due to a sudden acute episode of malnutrition or to long-standing chronic undernutrition (85).

Waterlow's classification (68)

When a child's age is known, measurement of weight enables almost instant monitoring of growth. Measurements of height assess the effect of nutritional status on long-term growth. Table 32 shows the Waterlow's classification.

Source: (68)

Waterlow's classification defines two groups for protein energy malnutrition:

- Malnutrition with retarded growth, in which a drop in the height/age ratio points to a chronic condition - shortness, or stunting;
- Malnutrition with a low weight for a normal height, in which the weight for height ratio is indicative of an acute condition - rapid weight loss, or wasting.

This combination of indicators makes it possible to label and classify individuals with reference to two roles: children with insufficient but well-proportioned growth and those with a normal height, but who are wasted (Table 33)

Arm circumference: (68)

Arm circumference yields a relatively reliable estimate of the body's muscle mass, the reduction of which is one of the most striking mechanisms by which the body adjusts to inadequate energy intakes. Arm circumference cannot be used before the age of one year; between ages one and five years, it hardly varies.

An arm circumference exceeding 13.5 cm is a sign of a satisfactory nutritional status, between 12.5 and 13.5 cm it indicates mild-moderate malnutrition and below 12.5 cm, severe malnutrition.

For the purpose of comparison, growth charts are provided with reference curves. These curves show the limit of normal growth. The WHO reference curves are based on extensive cross-sectional data of well-nourished healthy children, assembled by the National Centre for Health Statistics (NCHS). Malnutrition is defined by WHO as a weight-for-age below the median minus two standard deviations of the NCHS reference population (86).

Preventive measures

There is no simple solution to the problem of PEM. Many types of actions are necessary. The following is adapted from the 8th FAO/WHO Expert Committee on Nutrition (1) for the prevention of PEM in the community:

(a) Health promotion

1. Measures directed to pregnant and lactating women (education, distribution of supplements).
2. Promotion of breast-feeding.
3. Development of low cost weaning foods: the child should be made to eat more food at frequent intervals.
4. Measures to improve family diet.
5. Nutrition education - Promotion of correct feeding practices.
6. Home economics.
7. Family planning and spacing of births.
8. Family environment.
(b) Specific protection
1. The child’s diet must contain protein and energy-rich foods. Milk, eggs, fresh fruits should be given if possible.
2. Immunization.
3. Food fortification.
(c) Early diagnosis and treatment
1. Periodic surveillance.
2. Early diagnosis of any lag in growth.
5. Development of supplementary feeding programmes during epidemics.
(d) Rehabilitation
1. Nutritional rehabilitation services.
3. Follow-up care.
3. Xerophthalmia
Xerophthalmia (dry eye) refers to all the ocular manifestations of vitamin A deficiency in man. It is the most widespread and serious nutritional disorder leading to blindness (87) particularly in South-East Asia. Xerophthalmia is most common in children aged 1–3 years, and is often related to weaning. The younger the child, the more severe the disease. It is often associated with PEM. Mortality is often high in this age group (21). The victims belong to the poorest families. Associated risk factors include ignorance, faulty feeding practices and infections particularly diarrhoea and measles which often precipitate xerophthalmia. In some countries, epidemics of xerophthalmia have occurred in association with food donation programmes involving skimmed milk, which is totally devoid of vitamin A (88).
The States badly affected are the southern and eastern States of India notably Andhra, Tamil Nadu, Karnataka, Bihar and West Bengal. These are predominantly rice-eating States and rice is devoid of carotene. The North Indian States have relatively few cases of xerophthalmia (89).
Prevention and control
Prevention and control of xerophthalmia must be an integral part of primary health care. An overall strategy can be defined, according to WHO, in terms of short-term, medium-term and long-term action (24).
(a) Short-term action: A short-term preventive approach that has already demonstrated its efficacy is the administration of large doses of vitamin A orally, in recommended doses to vulnerable groups, on a periodic basis. This can be organized quickly and with a minimum of infrastructure.
(b) Medium-term action: An approach widely used to promote regular and adequate intake of vitamin A is fortification of certain foods with vitamin A. Addition of vitamin A to daldee in India is a typical example. Many other foods have also been considered for vitamin A fortification, viz. sugar, salt, tea, margarine and dried skimmed milk. Fortifying an appropriate food with vitamin A is a complex process, requiring a new technology. Among the programmes is choosing a food that is likely to be consumed in sufficient quantities by groups at risk (90).
(c) Long-term action: These are measures aimed at reduction or elimination of factors contributing to ocular disease, e.g., persuading people in general, and mothers in particular, to eat more generally dark green leafy vegetables or other vitamin A rich foods; promotion of breast-feeding for as long as possible; improvements in environmental health such as ensuring safe and adequate water supply and construction and maintenance of sanitary latrines to safeguard against diarrhoea; immunization against infectious diseases such as measles; prompt treatment of diarrhoea and other associated infections; better feeding of infants and young children; improved health education. All these are components of primary health care.
Vitamin A deficiency in India (VAD) (91)
VAD has been recognized as a major controllable public health and nutritional problem in India. An estimated 5.7 per cent children in India suffer from eye signs of VAD. Recent evidence suggests that even mild VAD probably increases morbidity and mortality in children, emphasizing the public health importance of this disorder. VAD is one of the major deficiencies among lower income strata population in India.
Though the prevalence of severe forms of VAD such as corneal ulcers is small. In contrast, a keratomalacia which has in general become rare, Bitot spots were present in varying magnitudes in different parts of the country as reported by National Nutritional Monitoring Bureau in 2003. The prevalence was higher than WHO cut-off level of 0.5 per cent, indicating the public health significance of the problem of VAD. There is a huge inter-state variation in the prevalence of VAD among children. It is also a matter of concern that only 21 per cent of children of age 12 to 35 months receive a vitamin A dose. Less than 10 per cent coverage was reported in Nagaland, Uttar Pradesh reported 7.3 per cent coverage. Only states such as Tamil Nadu (37.2 per cent), Telangana (11.9 per cent) and West Bengal (41.2 per cent) have better coverage, though it is still low.
In India, in 1970 a national programme for prevention of nutritional blindness was initiated to fight this deficiency. The beneficiaries of this programme were pre-school children (1–5 years). The programme was modified in 1992 to cover children in age group of nine months to three years only. Since Tenth Five Year Plan vitamin A supplementation exists as an integral component of RCH programme which is now a part of NRHM. The guidelines issued in November 2006 cover children up to 5 years of age.
The programme focuses on (92): (a) Promoting consumption of vitamin A rich foods by pregnant and lactating women and by children under five years of age and appropriate breast-feeding; (b) Administration of massive dose of vitamin A up to five years. First dose of 100,000 IU with measles vaccination at nine months and subsequent doses of 200,000 IU each, every six months up to the age 5 years; (c) For sick children – all children with xerophthalmia to be treated at health facilities; all children suffering from measles to be given one dose of vitamin A if they have not received it in the previous one month; all cases of severe malnutrition to be given one additional dose of vitamin A (92).
4. Nutritional anaemia

Nutritional anaemia is a disease syndrome caused by malnutrition in its widest sense (54). It has been defined by WHO as "a condition in which the haemoglobin content of blood is lower than normal as a result of a deficiency of one or more essential nutrients, regardless of the cause of such deficiency" (52). Anaemia is established if the haemoglobin is below the cut-off points recommended by WHO (Table 13). By far the most frequent cause of nutritional anaemia is iron deficiency, and less frequently folate or vitamin B12 (49).

The problem

WORLD

Nutritional anaemia is a worldwide problem with the highest prevalence in developing countries. It is found especially among women of child-bearing age, young children and during pregnancy and lactation. It is estimated to affect nearly two-thirds of pregnant and one-half of non-pregnant women in developing countries (93). The populations of developed countries are not by any means completely free of anaemia, and a significant percentage of women of child-bearing age (estimated between 4 and 12 per cent) suffer from anaemia (94).

INDIA

Iron deficiency anaemia is the most widespread micronutrient deficiency affecting all age groups irrespective of gender, cast, creed and religion. In India, this silent emergency is rampant among women belonging to reproductive age group (15-49 years), children (6-35 months) and low socio-economic strata of the population. Overall, 72.7 per cent of children up to the age of 3 years in urban areas and 81.2 per cent in rural areas are anaemic.

While analyzing the data for states with anaemia level of 70% among children, it was found that, except for Punjab, all other states had more than 50% prevalence of anaemia among pregnant women. This again reiterates the strong relationship between anaemia levels of mothers and children. Also the overall prevalence has increased from 74.2% (1998-99) to 79.2% (2005-06). Nagaland had the lowest prevalence (44.3%), Goa was next (49.3%) followed by Mizoram (51.7%), Bihar had the highest prevalence (87.6%) followed closely by Rajasthan (85.7%), and Karnataka (82.7%). Moderate and severe anaemia is seen even among the educated families both in urban and rural areas. There are inter-state differences in prevalence of anaemia that are perhaps attributable partly to differences in dietary intake and partly to access to health care (91).

As per District Level Health Survey (DLHS) (2002-04), prevalence of anaemia in adolescent girls is very high (72.6%) in India, with prevalence of severe anaemia among them much higher (21.1%) than that in preschool children (2.1%). In adolescent girls, educational or economic status does not seem to make much of a difference in terms of prevalence of anaemia. Prevention, detection, or management of anaemia in adolescent girls has till now not received much attention. In view of the high prevalence of moderate and severe anaemia in this group and the fact that many of them get married early, conceive, and face the problems associated with anaemia in pregnancy, it is imperative to screen them for anaemia and treat them.

Iron deficiency can arise either due to inadequate intake or poor bioavailability of dietary iron or due to excessive losses of iron from the body. Although most habitual diets contain seemingly adequate amounts of iron, only a small amount (less than 5 per cent) is absorbed (96). This poor bio-availability is considered to be a major reason for the widespread iron deficiency (95). Women lose a considerable amount of iron especially during menstruation. Some of the other factors leading to anaemia are malaria and hookworm infestations. In addition mothers who have born children at close intervals become anaemic due to the additional demands of the rapid pregnancies and the loss of blood in each delivery.

Megaloablastic anaemia is not encountered frequently in general population, but it occurs occasionally in pregnant women from poor income groups. It is possible that the widespread iron deficiency (microcytic anaemia) could mask megaloblastic anaemia. In a recent study, sub-clinical folate deficiency was found to be about 30 per cent in pregnant women from Rural North India. A high level of sub-clinical folate deficiency was also reported in semi-urban school children. There are some sporadic reports indicating its prevalence in adults (9).

Detrimenial effects

The detrimental effects of anaemia can be seen in three important areas (49):

(a) Pregnancy: Anaemia increases the risk of maternal and foetal mortality and morbidity. In India, 19 per cent of maternal deaths were found to be due to anaemia (54). Conditions such as shortness, premature births, postpartum haemorrhage and low birth weight were especially associated with low haemoglobin levels in pregnancy. (b) Infection: Anaemia can be caused or aggravated by parasitic diseases, e.g., malaria, intestinal parasites. Further, iron deficiency may impair cellular responses and immune functions and increase susceptibility to infection (c) Work capacity: Anaemia (even when mild) causes a significant impairment of maximal work capacity. The more severe the anaemia, the greater the reduction in work performance, and thereby productivity. This has great significance on the economy of the country.

Interventions

An estimation of haemoglobin should be done to assess the degree of anaemia. If the anaemia is "Severe", less than 10 g/dl high doses of iron or blood transfusion may be necessary. If haemoglobin is between 10-12 g/dl, other interventions are necessary:

(1) Iron and folic acid supplementation

In order to prevent nutritional anaemia among mothers and children, the Government of India sponsored a National Nutritional Anaemia Prophylaxis Programme during the Fourth Five Year Plan. The Programme is based on daily supplementation with iron and folic acid tablets to prevent mild and moderate cases of anaemia. The beneficiaries are "at risk" groups viz pregnant women, lactating mothers and children under 12 years.

Eligibility criteria (97): These are determined by the haemoglobin levels of the patients. If the haemoglobin is between 10 and 12, daily supplement with iron and folic acid tablets is advised; if it is less than 10 g, the patient is referred to the nearest primary health centre.

Dosage: (a) MOTHERS: One tablet of iron and folic acid containing 100 mg of elemental iron (300 mg of ferrous sulphate) and 0.5 mg of folic acid should be given daily. The daily administration should be continued until 2 to 3 months after haemoglobin level has returned to normal so that iron
It is necessary that estimation of haemoglobin is repeated at 3–4 month intervals. The exact period of supplementation will depend upon the progress of the beneficiary. (b) CHILDREN: if anaemia is suspected, a screening test for anaemia may be done on infants at 6 months, and 1 and 2 years of age. One tablet of iron and folic acid containing 20 mg of elemental iron (60 mg of ferrous sulphate) and 0.1 mg of folic acid should be given daily for 100 days. For children 6–60 months, ferrous sulphate and folic acid is to be provided in a liquid formulation. For safety sake, the liquid formulation should be dispensed in bottles so designed that only 1 ml can be dispensed each time. School children, 6 to 10 year old and adolescents are also to be included in the national programme. Children 6–10 years of age are to be provided 30 mg elemental iron and 250 mcg folic acid per day for 100 days. Adolescents are given the same dosage and duration as adults (92).

(2) Iron fortification

The WHO experts (49) did not recommend iron fortification strategy for control of anaemia in regions where its prevalence is high. However, studies in India at the National Institute of Nutrition, Hyderabad showed that simple addition of ferric ortho-phosphate or ferrous sulphate with sodium bicarbonate was enough to fortify salt with iron (98). When consumed over a period of 12–18 months, iron fortified salt was found to reduce prevalence of anaemia significantly. Fortification of salt with iron has been accepted by the Government of India as a public health approach to reduce prevalence of anaemia. Commercial production of iron fortified salt was started in 1985 (98).

Iron fortification has many advantages over iron supplementation. As salt is a universally consumed dietary item, all segments of the population stand to benefit. No special delivery systems are required (53).

(3) Other strategies

There are other strategies such as changing dietary habits, control of parasites and nutrition education. These are longterm measures applicable to situations where the prevalence and severity of anaemia are lower. Cost and time involved to meet the desired goal through these strategies are disproportionately high (53).

5. Iodine deficiency disorders (IDD)

Iodine deficiency is yet another major nutritional problem in India. Previously, iodine deficiency was equated with goitre. In recent years, it has become increasingly clear that iodine deficiency leads to a much wider spectrum of disorders commencing with the intrauterine life and extending through childhood to adult life with serious health and social implications. Table 16 presents the iodine deficiency disorders in approximate order of increasing severity. The social impact of iodine deficiency arises not so much from goitre as from the effect on the central nervous system (56).

The problem

Whereas goitre has ceased to be a major problem in many developed countries (although not eradicated) it continues to be a serious health problem in many Third World Countries. For example iodine deficiency is a health problem of considerable magnitude in India and the neighbouring countries of Bangladesh, Bhutan, Myanmar, Indonesia, Nepal, Sri Lanka and Thailand. More people are affected and levels of severity are higher in South-East Asia than anywhere else in the world (99).

It has always been thought in India that goitre and cretinism were only found to a significant extent in the “Himalaya goitre belt” which is the world’s biggest goitre belt. It stretches from Kashmir to the Naga Hills in the east, extending about 2,400 km and affecting the northern states of Jammu and Kashmir, Himachal Pradesh, Punjab, Haryana, Delhi, Uttar Pradesh, Bihar, West Bengal, Sikkim, Assam, Arunachal Pradesh, Nagaland, Mizoram, Meghalaya, Tripura and Manipur. In recent years renewed surveys outside the conventional goitre belt have identified endemic foci of iodine deficiency and the associated IDD in parts of Madhya Pradesh, Gujarat, Maharashtra, Andhra Pradesh, Kerala, Karnataka and Tamil Nadu. More and new areas are being identified. Even areas near the sea coast like Bharuch district in Gujarat and Ernakulam district in Kerala are found goitre-affected. In short, no State in India can be said to be entirely free from goitre (Fig. 4).

FIG. 4

Goitre endemic areas in India

The magnitude of the problem in India is far greater than what had been estimated in 1960s, when it was estimated that about 9 million persons were affected by goitre. Results of sample surveys conducted in 325 districts covering all the states/UTs have revealed that 263 districts are endemic where the prevalence of IDD is more than 10 per cent. It is estimated that more than 71 million persons are suffering from goitre and other iodine deficiency disorders in the country (100).

Goitre control

There are four essential components of national goitre control programme. These are iodized salt or oil, monitoring and surveillance, manpower training and mass communication.

1. Iodized salt

The iodization of salt is now the most widely used prophylactic public health measure against endemic goitre. In India the level of iodization is fixed under the Prevention of Food Adulteration (PFA) Act and is not less than 30 ppm at the production point, and not less than 15 ppm of iodine at the consumer level (98). Iodized salt is most economical, convenient and effective means of mass prophylaxis in
enemic areas. Under the national IDD control activities, the Government of India proposed to completely replace common salt with iodized salt in a phased manner (98).

The National Institute of Nutrition at Hyderabad has come out with a new product, common salt fortified with iron and iodine. Community trials have been launched to evaluate the efficacy of the "two-in-one" salt (94).

Iodized oil: Another method which has demonstrated its efficacy for controlling goitre is intramuscular injection of iodized oil (mostly poppy seed oil). Scientists at the National Institute of Nutrition, Hyderabad have now successfully developed a process to produce iodized oil in safflower or saffola oil (101).

The advantage of the injection procedure is that an average dose of 1 ml will provide protection for about 4 years. Although more expensive than iodated salt, this method has the advantage that it can be applied rapidly and in places where iodization of salt is not feasible or iodated salt is in short supply. However, the difficulty with this procedure is one of logistics, i.e., in reaching every victim or potential victim of IDD for the injection, which means that this approach is less practicable.

Iodized oil, oral: The oral administration of iodine as iodized oil or as sodium iodate tablets, is technically simpler than the injection method. Limited research has found that these procedures are effective against goitre but more costly than intramuscular injections.

2. Iodine monitoring

Countries implementing control programmes require a network of laboratories for iodine monitoring and surveillance. These laboratories are essential for a) iodine excretion determination and b) determination of iodine in water, soil and food as part of epidemiological studies, and c) determination of iodine in salt for quality control.

Neonatal hypothyroidism is a sensitive pointer to environmental iodine deficiency and can thus be an effective indicator for monitoring the impact of a programme (99).

3. Manpower training

It is vital for the success of control that health workers and others engaged in the programme be fully trained in all aspects of goitre control including legal enforcement and public education.

4. Mass communication

Mass communication is a powerful tool for nutrition education. It should be fully used in goitre control work. Creation of public awareness is central issue of a successful public health programme.

5. Hazards of iodization

A mild increase in incidence of thyrotoxicosis has now been described following iodized salt programmes. An increase in lymphocytic thyroiditis (Hashimotos disease) has also been claimed. The risk of iodism or iodide goitre however seems to be very small (58).

6. Endemic fluorosis

In many parts of the world where drinking water contains excessive amounts of fluorine (3-5 mg/L), endemic fluorosis has been observed. Endemic fluorosis has been reported to be an important health problem in certain parts of the country, e.g., Andhra Pradesh (Nellore, Nalgonda and Prakasam districts), Punjab, Haryana, Karnataka, Kerala and Tamil Nadu (60). The toxic manifestation of fluorosis comprise the following:

(a) Dental fluorosis: Fluorosis of dental enamel occurs when excess fluoride is ingested during the years of tooth calcification. The defect occurs during the first 7 years of life (101). It is characterized by "mottling" of dental enamel, which has been reported at levels above 1.5 mg/L intake (102). The teeth lose their shiny appearance and chalky-white patches develop on them. This is the early sign of dental fluorosis. Later the white patches become yellow and sometimes brown or black. In severe cases, loss of enamel gives the teeth a corroded appearance. Mottling is best seen on the incisors of the upper jaw. It is almost entirely confined to the erupted teeth and develops only during the period of formation (61).

(b) Skeletal fluorosis: This is associated with lifetime daily intake of 3.0 to 6.0 mg/L or more (102). There is heavy fluoride deposition in the skeleton. When a concentration of 10 mg/L is exceeded, crippling fluorosis can ensue (103). It leads to permanent disability.

(c) Genus valgum: A new form of fluorosis characterised by genu valgum and osteoporosis of the lower limbs has been reported in some districts of Andhra Pradesh and Tamil Nadu (104). The syndrome was observed among people whose staple was sorghum (towar). Further studies showed that diets based on sorghum promoted a higher retention of ingested fluoride than do diets based on rice (14).

Intervention

(a) Changing the water source: One solution to the problem is to find a new source of drinking water with a lower fluoride content (0.5 to 0.8 mg/L) if that is possible. Running surface water or streams lower quantities of fluorides than ground water; sources such as wells. (b) Chemical treatment: If the above is not possible, the water can be chemically defluoridated in a water treatment plant. Even though such treatment is moderately expensive (101). The National Environmental Engineering Research Institute, Nagpur, developed a technique for removing fluoride by chemical treatment. It is called Nalgonda technique for defluoridation of water (105). It involves the addition of two chemicals, lime and alum in sequence followed by flocculation, sedimentation and filtration. (c) Other measures: Fluoride supplements should not be prescribed for children who drink fluoridated water. The use of fluoride toothpaste in areas of endemic fluorosis is not recommended for children up to 6 years of age (101).

7. Lathyrism

Lathyrism is a paralyzing disease of humans and animals. In the humans it is referred to as "neurolathyrism" because it affects the nervous system, and in animals as "osteolathyrism" (odontoalism) because the pathological changes occur in the bones resulting in skeletal deformities (8). Neurolathyrism is a crippling disease of the nervous system characterized by gradually developing spastic paralysis of lower limbs, occurring mostly in adults consuming the pulse, Lathyrus sativus in large quantities.

The problem:

Neurolathyrism is prevalent in parts of Madhy Pradesh, Uttar Pradesh, Bihar and Orissa. It has also been reported in Maharashtra, West Bengal, Rajasthan, Assam and Gujarat where the pulse is grown. The magnitude of the problem can
be assessed from the fact that at one time in Rewa and Satna districts of Madhya Pradesh alone, there were 25,000 and 32,000 cases respectively. According to reports, there are no fresh outbreaks of the disease in endemic areas. This is attributed to the shifting trends in agronomic practices in the region (106). Lathyriasis has also been reported to occur in Spain and Algeria where Lathyrus is eaten (8).

The pulse

Lathyrus sativus is commonly known as “Khoezari dhal”. It is known by local names such as Teora dhal, Lak dhal, Bata, Gharas, Matra etc. (106). The seeds of lathyrus have a characteristic bulging shape and grey colour. When dehusked the pulse looks similar to red gram dhal or bengal gram dhal. Like other pulses, lathyrus is a good source of protein, but for its toxin which affects the nervous. It is eaten mostly by the poor agricultural labourer because it is relatively cheap. Studies have shown that diets containing over 30% of this dhal if taken over a period of 2-6 months will result in neurotoxicity.

The toxin

The toxin present in lathyrus seeds has been identified as Beta oxalyl amino alanine (BOAA). It has been isolated in crystalline form and is water soluble; the property has been made use of in removing the toxin from the pulse by soaking it in hot water and rejecting the soak water. Studies indicate that there is a blood-brain barrier to this toxin. In order to overcome this barrier, the pulse must be eaten in large amounts over a period of time for 2 months or more. Besides BOAA several other toxins have also been reported (107).

The disease

The disease affects mainly young men between the age of 15 to 45 years and manifests itself in stages: (a) Latent stage: The individual is apparently healthy, but when subjected to physical stress exhibits unexplained gait. Neurological examination shows characteristic physical signs. This stage is considered important from the preventive aspect, since at this stage, if the pulse is withdrawn from the diet, it will result in complete remission of the disease. (b) No-stick stage: The patient walks with short jerky steps without the aid of a stick. A large number of patients are found in this stage. (c) One-stick stage: The patient walks with a crossed gait with a tendency to walk on toes. Muscular stiffness makes it necessary to use a stick to maintain balance. (d) Two-stick stage: The symptoms are more severe. Due to excessive bending of knees and crossed legs, the patient needs two crutches for support. The gait is slow and clumsy and the patient gets tired easily after walking a short distance. (e) Crawler stage: Finally the erect posture becomes impossible as the knee joints cannot support the weight of the body. There is atrophy of the thigh and leg muscles. The patient is reduced to crawling by throwing his weight on his hands (106).

Interventions

The possible interventions for the prevention and/or control of lathyriasis are:

(a) Vitamin C prophylaxis: Although this condition is believed to be irreversible, in certain instances the damage could be repaired by the daily administration of 500-1000 mg of ascorbic acid for a week or so. The damage could also be prevented by generous provision of ascorbic acid in the lathyrogeneic diet, as demonstrated in guinea pigs and monkeys.

(b) Banning the crop: This is an extreme step not feasible for immediate implementation. The Prevention of Food Adulteration Act in India has banned lathyrus in all forms – whole, split or flour. But the ban is not operative where it is needed, viz. Madhya Pradesh, Bihar, Orissa and Gujarat where the pulse is widely grown.

If however, it is not possible to avoid consuming khesari dhal, it is desirable that the proportion of the dhal should never form more than a quarter of the total amount of cereals and pulses eaten per day.

(c) Removal of toxin

(1) Soaking method: Since the toxins are water soluble, they can be removed by soaking the pulse in hot water. This method can be practised at home. A large quantity of water is boiled and the yolk is soaked in hot water for 2 hours, after which the soaked water is drained off completely. The pulse is washed again with clean water, then drained off and dried in the sun. The pulse is then used for consumption. The drawback with this method is that it entails loss of vitamins and minerals.

(2) Parboiling: An improved method of detoxicating the pulse is “parboiling”, as is done in the case of parboiled rice. This technique is suitable for large scale operation. Simple soaking in lime water overnight followed by boiling is credited to destroy the toxin. This treatment also destroys trypsin inhibitors. Lime is easily available as it is used with betel leaves.

(c) Education: The public must be educated on the dangers of consuming this pulse and the need for removing its toxin before consumption.

(d) Genetic approach: Certain strains of lathyrus contain very low levels of toxin (0.1%). The selective propagation and cultivation of such strains may be the most effective way to eradicate lathyriasis without any drastic change in the food habits of the people. Low toxin varieties can be obtained from the Indian Agricultural Research Institute, New Delhi.

(e) Socio-economic changes: In the final analysis, it is only socio-economic changes or overall development that can root out lathyriasis.

NUTRITIONAL FACTORS IN SELECTED DISEASES

1. Cardiovascular disease

It is now generally agreed that diet governs many situations favouring the onset of “heart disease”, particularly coronary heart disease. Of all the factors associated with CHD (e.g., plasma cholesterol, high blood pressure, cigarette smoking), lack of physical activity plasmas chloride has a very high statistical significance with the incidence of CHD. The risk of CHD appears to increase as the plasma cholesterol concentration rises (138). Various studies have supported the role of elevated blood levels of cholesterol and low density lipoproteins (LDL) in the development of atherosclerosis. Geographical studies have shown that there is no population in whom CHD is common that does not have a relatively high mean level of plasma total cholesterol (TC) in adults (15). These observations have been reinforced by metabolic studies. In addition trials of the effect of dietary changes on CHD have suggested that altering the fatty acid composition of the diet in favour of greater intake of polyunsaturated fatty acids (PUFA) and less intake of saturated fats, while restricting the intake of fat
calories to less than 30 per cent of the total calories, may lower the risk that CHD will subsequently develop (109). The evidence of association is now so strong for cholesterol and CHD that the WHO Expert committee (1982) considered its effect to be "causal" in populations although this cannot be claimed yet for individuals (15). The WHO Expert Committee (15) concludes that there is a well established triangular relationship between habitual diet, blood cholesterol levels and CHD. The current report of the expert group of the ICMR (2010) on Nutrient Requirement and Recommended Dietary Allowances for Indians endorses the views.

**Cholesterol**

Cholesterol occurs in all foods of animal origin. Part of it is synthesized in the body. The plasma cholesterol is determined by (a) the amount absorbed from food (b) the amount synthesized in the body (c) the rate of catabolism and excretion in the bile (d) intestinal reabsorption of bile acids, and (e) the equilibrium between plasma and tissues. The extent to which cholesterol intake influences total cholesterol levels is highly variable.

**Lipoproteins**

Cholesterol is carried in plasma lipoproteins. Lipoproteins are divided into four major classes - chylomicrons, very low-density lipoproteins (VLDLs), low-density lipoproteins (LDLs) and high-density lipoproteins (HDLs). The total serum cholesterol is the sum of the cholesterol in 3 lipoprotein fractions, viz. VLDL, LDL and HDL cholesterol. Most of the serum cholesterol (close to 50 per cent) is in LDL. Whereas LDL is dominated by its cholesterol content, VLDL is dominated by its triglyceride content.

LDL has been shown to function in the delivery of cholesterol to body cells. Excessive level of LDL thus leads to the accumulation of cholesterol in tissue cells particularly the smooth muscle cells of the vascular system. It is thus involved in the atherosclerotic process. In contrast, HDL functions in the removal of cholesterol from cells. This mechanism underlines its protective effect in CHD. From long-term observations it became quite clear that HDL levels, the higher they are, the more protective they seem to be against CHD.

**Fatty acids**

In populations where the plasma cholesterol is high, there is also generally a high consumption of saturated fats. Clinical studies on selected volunteers under well-defined conditions have clearly demonstrated that a high intake of saturated fatty acids over several weeks or months causes an increase in plasma cholesterol. The cholesterol-raising effect is mainly produced by C16:0, C18:0 and C18:1 acids; stearic acid and fatty acids with less than 12 carbon atoms have a smaller effect on plasma cholesterol. The mechanisms by which these saturated fatty acids act (possibly on cholesterol synthesis) is not fully known.

Dietary unsaturated fatty acids with two or more double bonds have been shown to lower plasma cholesterol. The mechanism of reduction of serum cholesterol by polyunsaturated fatty acids is not clear but includes reduced synthesis of VLDL. The proposition has often been made that a low HDL/LDL ratio favours the development of atheroma, thus favouring the onset of CHD (110).

Polyunsaturated fatty acids (e.g., linoleic and arachidonic acids) have an additional role, that is, to inhibit platelet aggregation and thus prevent thrombus formation. Recent research indicates that arachidonic acid metabolites in the vascular endothelium to form two important metabolites, namely prostaacyclin and thromboxane (Fig. 5). These two compounds have opposing effects on the cardiovascular system. Whereas thromboxane induces platelet aggregation, prostaacyclin inhibits the same and prevents intravascular thrombus formations. Prostaacyclin was found also to relax coronary blood vessels, thus opposing the action of thromboxane. It has been suggested that generation of prostaacyclin in the biochemical mechanism underlying the well-known ability of blood vessels to resist platelet aggregation. Linoleic acid which is the main precursor of arachidonic acid is therefore regarded as the body's best 'bulwark' against CHD. In short, essential fatty acids have in the last decade come to be regarded as of major importance in clinical nutrition.

**FIG. 5**

Steps in the conversion of arachidonic acid to prostaclin, etc.

It has been shown that cholesterol in blood can be reduced by controlling the amount and type of fat in the diet. However, severe populations, particularly in Africa and in the South Pacific have intakes of fat similar to those observed in Western countries, but the average plasma cholesterol level remains below 200 mg/dl, and coronary heart disease is rare. It has been argued that this discrepancy may be due to a "favourable" intrinsic (possibly genetic) mechanism for lipid handling, when receiving a diet shown experimentally to raise total cholesterol. This illustrates an important interplay between dietary and genetic determinants of individual blood cholesterol levels (15).

Evidence is emerging that ischaemic myocardium may not metabolise all fatty acids equally, and that the accumulation of some of these in the myocardium may be more closely associated with sudden cardiac death (110).

**Triglycerides**

In a very large proportion of individuals with a raised cholesterol level, the blood concentration of triglycerides (TG) is also markedly increased. Some workers have indeed claimed that correlation between TG and CHD is as good as that between total serum cholesterol and CHD. Recently it has been shown that TG levels act as a significant independent risk factor for CHD (102). Both cholesterol and TG are associated with specific proteins in the plasma to form lipoproteins.
The most important determinant of TG level is the activity of the enzyme, lipoprotein lipase in the endothelial lining of the capillaries and in a variety of tissues. This enzyme removes TG particularly from the very low density lipoproteins (VLDL) and converts these to the lipoproteins of higher density. In certain genetically determined diseases, this enzyme may be absent. A reduction in its activity or a reduced capacity to deal with increased levels of TG may be important in more common diseases such as diabetes where high concentrations of TG are often observed.

Carbohydrate
Coronary heart disease rates are lowest in populations eating high carbohydrate diets. Support for the hypothesis that consumption of complex carbohydrates may decrease the risk of CHD comes from historical trends in food consumption patterns and mortality rates in US. It is generally recognized that such mortality rates were quite low until 1960. After 1960 there was a steady increase in the mortality rate until 1985 when a decline began (109). The principal nutritional change that has occurred since the early 1950 has been a decrease in the consumption of dietary carbohydrate. Further support comes from feeding studies. A decrease in serum cholesterol was observed during the vegetable feeding study. Neither high carbohydrates nor high sucrose feeding has induced atherosclerosis in animals. An inverse association of fiber intake with the risk of CHD has also been observed (111).

Salt
There are good and consistent correlations between dietary sodium intake and the incidence of hypertension. Thus the highest incidence of hypertension in Japan where the sodium intake is above 400 mmol/day, while primitive societies ingesting less than 60 mmol/day have virtually no hypertension. Susceptible individuals in primitive populations who change from low to high intake of sodium have been found to develop hypertension. Hypertension can be successfully treated with a drastically low sodium diet (less than 10 mmol/day) (110).

2. Diabetes
In a diabetic, there is impaired metabolism of glucose in the body, which leads to excess of glucose in blood and urine. Insulin helps in checking and maintaining the level of glucose in blood. Insulin deficiency leads to accelerated utilization of energy reserves from fat stores. The fatty acids are oxidized by liver to ketone bodies. Excess of ketone bodies leads to their accumulation in urine. This condition is known as ketoacidosis and can result in diabetic coma. Due to insulin deficiency excess of fatty acids are converted to triglycerides. In diabetes these accumulate in the blood. Insulin is also important for synthesis of proteins and deficiency of insulin leads to muscle wasting.

Studies in England showed that diabetics ate an average 1000 kcal per day more than non-diabetics. It was also found that most diabetics were non-manual occupations than non-diabetics. And the diet of diabetics did not appear to differ in anyanner from that of non-diabetics, except in quantity. There is no sound evidence that any specific dietary factor is diabetogenic.

It has been suggested that deficiencies of trace elements such as chromium, copper and zinc may play a role in the pathogenesis of diabetes mellitus, but clinical evidence is lacking (112). Malnutrition-related diabetes mellitus has recently attracted attention. Protein deficiency may be involved in the pathogenesis of some forms of diabets. Excessive consumption of alcohol can increase the risk of diabetes by damaging the pancreas and liver and by promoting obesity.

3. Obesity
In richer countries and in some developing countries, obesity is a health problem. The connection between severe obesity and premature death from diabetes, hypertension and CHD is well established (113). The basic cause of obesity is overnutrition. A diet containing more energy than needed may lead to prolonged postprandial hyperlipidaemia and to deposition of triglycerides in adipose tissue resulting in obesity (110). It is known that a relative insulin resistance takes place in obesity in peripheral tissues, mainly adipose tissues, while the insulin secretion is normal or increased. The demonstrated reduction in the sensitivity to insulin of the large adipocytes can be attributed to the decreased affinity of the insulin receptors or to a reduction in their number in the cell membranes. Through a feedback mechanism the insulin secretion is stepped up, thus leading to a state of hyperinsulinism.

From a practical point of view all hypotheses concerning the genesis of obesity could be put down to over-nutrition, to a hyper-energy food intake. This is a sound basis for preventive and therapeutic recommendations (114).

4. Cancer
It is postulated that 80 per cent of cancers may be due to environmental factors, and it is possible that some dietary factors may be involved. Existing knowledge is reviewed briefly as follows:

(a) Dietary fat
Population surveys have shown a strong positive correlation between cancer colon and dietary intake of fat (115). It has been suggested that the high fat intake accounts for the incidence of colon cancer (116). Dietary fat is believed to increase the secretion of bile acids in the bowel which are then metabolized by bacterial flora into carcinogens or co-carcinogens (117). However, no known carcinogen has yet been identified from faeces and the evidence is thus incomplete.

A positive correlation between per capita consumption of dietary fat and breast cancer rates has also been noted. A reduction in dietary fat may alter the risk of breast cancer (118), perhaps by increasing oestrogen production or prolactin release (119).

(b) Dietary fibre
Several studies indicate that the risk of colon cancer is inversely related to the consumption of dietary fibre, which may protect against intestinal carcinogens or precursors by dilutional or other effects (120). Although the available epidemiological data are not entirely consistent, the weight of evidence generally supports the hypothesis that fibre protects against colon cancer (116).
(c) Micronutrients

Micronutrients may also have a protective influence, since cancers of the lung and several other sites have been associated with a low intake of vitamin A (117). The risk of stomach cancer has been related to a deficiency of vitamin C, which may act by in-biting the formation of carcinogenic nitrosamines in the stomach (121). Trace elements (e.g., selenium) have also been implicated in the aetiology of cancer (116).

(d) Food additives and contaminants

Food additives and contaminants (e.g., preservatives, artificial colours, artificial sweeteners, pesticides, flavours, anti-oxidants) have always been under suspicion as possible carcinogens in their long-term effects. Food processing involves exposure to high temperature, oxidation, polymerisation, production of nitrosamines, poly cyclic aromatic hydrocarbons, etc which are injurious to health. It is thought in some quarters that nitrosamines are responsible for certain types of gastric carcinoma. Saccharin and cyclamate are weak bladder carcinogens or co-carcinogens in laboratory animals, but the risk in man is very small if present at all (122). Aflatoxin is a carcinogenic metabolite. Coffee intake has been associated with bladder cancer and recently with pancreatic cancer (123) but causal relationships have not been established. The mutagenic properties of food additives are under constant surveillance.

(e) Alcohol

Heavy drinking increases the risk of liver cancer. It is estimated that alcohol contributes to about 3 per cent of all cancer deaths (124). Some recent studies have suggested that beer consumption may be related to cancer risk, but the association has not been confirmed (177).

The above review indicates that much evidence has accumulated to indicate that nutrition has an influence on cancer incidence and mortality. There is in this field a remarkable dearth of facts and an abundance of speculation.

---

**ASSESSMENT OF NUTRITIONAL STATUS**

The nutritional status of an individual is often the result of many interrelated factors. It is influenced by the adequacy of food intake of both in terms of quantity and quality and also by the physical health of the individual (129). The nutritional status of a community is the sum of the nutritional status of the individuals who form that community. The main objective of a "comprehensive" nutritional survey is to obtain precise information on the prevalence and geographic distribution of nutritional problems of a given community, and identification of individuals or population groups "at risk" or in greatest need of assistance. In the absence of this information, problems cannot be defined and policies formulated. The purpose of nutritional assessment is to develop a health care programme that meets the needs defined by that assessment, including evaluation of the effectiveness of such programmes (58).

In nutritional surveys, it is not necessary to examine all the persons in a given community. Examination of a random and representative sample of the population covering all ages and both sexes in different socio-economic groups is sufficient to be able to draw valid conclusions. All surveys should be planned with the aid of expert statistical advice. Decisions of many kinds have to be made in advance: duration of survey; type of survey whether cross-sectional or longitudinal; standardization of measurement techniques and survey instruments, etc. Opportunity might be taken of conducting, perhaps on a sub-sample, an intensive investigation of nutritional status.

**Assessment methods**

The assessment of the nutritional status involves various techniques. Proper evaluation demands a many-angled approach, covering all the different stages in the natural history of nutritional diseases, including prepathogenesis stage as shown in Fig. 6 (126).

The assessment methods include the following:

1. Clinical examination
2. Anthropometry

---

**FIG. 6**

Methods of nutritional assessment and their relationship to the natural history of disease
3. Biochemical evaluation
4. Functional assessment
5. Assessment of dietary intake
6. Vital and health statistics
7. Ecological studies.

The different methods used for the appraisal of nutritional status are not mutually exclusive; on the contrary, they are complimentary.

1. Clinical examination

Clinical examination is an essential feature of all nutritional surveys since their ultimate objective is to assess levels of health of individuals or of population groups in relation to the food they consume. It is also the simplest and the most practical method of ascertaining the nutritional status of a group of individuals. There are a number of physical signs, some specific and many non-specific, known to be associated with states of malnutrition. When two or more clinical signs characteristic of a deficiency disease are present simultaneously, their diagnostic significance is greatly enhanced. A WHO Expert Committee (127) classified signs used in nutritional surveys into three categories as those:

(a) not related to nutrition, e.g., alopecia, pyorrhea, pterygium
(b) that need further investigation, e.g., malar pigmentation, corneal vascularization, geographic tongue
(c) known to be of value, e.g., angular stomatitis, Boutet’s spots, calf tenderness, absence of knee or ankle jerks (beri-beri), enlargement of the thyroid gland (endemic goitre), etc.

However, clinical signs have the following drawbacks:
(a) malnutrition cannot be quantified on the basis of clinical signs
(b) many deficiencies are unaccompanied by physical signs
(c) lack of specificity and subjective nature of most of the physical signs.

To minimize subjective and objective errors in clinical examination, standard survey forms or schedules have been devised covering all areas of the body. A specimen nutrition assessment schedule is given at the end of this chapter (p. 116).

2. Anthropometry

Anthropometric measurements such as height, weight, skinfold thickness and arm circumference are valuable indicators of nutritional status. In young children, additional measurements such as head and chest circumference are made. If anthropometric measurements are recorded over a period of time, they reflect the patterns of growth and development, and how individuals deviate from the average at various ages in body size, build and nutritional status. Anthropometric data can be collected by non-medical personnel, given sufficient training. This subject is discussed in detail in Chapter 9.

3. Laboratory and biochemical assessment

(a) LABORATORY TESTS: (i) Hemoglobin estimation: It is the most important laboratory test that is carried out in nutrition surveys. Haemoglobin level is an useful index of the overall state of nutrition irrespective of its significance in anaemias. An RBC count and a haemacrit determination are also valuable. (ii) Stools and urine: Stools should be examined for intestinal parasites. History of parasitic infestation, chronic dysentery and diarrhoea provides useful background information about the nutritional status of persons. Urine should also be examined for albumin and sugar.

(b) BIOCHEMICAL TESTS: With increasing knowledge of the metabolic functions of vitamins and minerals, assessment of nutritional status by clinical signs has given way to more precise biochemical tests which may be applied to measure individual nutrient concentration in body fluids (e.g., serum retinol, serum iron) or detection of abnormal amounts of enzymes in urine (e.g., urinary iodine) frequently after a loading dose, or measurement of enzymes in which the vitamin is a known co-factor (for example in riboflavin deficiency) to help establish malnutrition in its preclinical stages.

Biochemical tests are time-consuming and expensive. They cannot be applied on a large scale, as for example in the nutritional assessment of a whole community. They are often carried out on a subsample of the population. Most biochemical tests reveal only current nutritional status; they are useful to quantify mild deficiencies. If the clinical examination has raised a question, then the biochemical tests may be invoked to prove or disprove the question raised. A short list of currently advocated biochemical tests applicable in nutritional surveys is given in Table 34.

4. Functional indicators

Static indices of nutritional status (biochemical indicators) will continue to play an important role as they are well-established and familiar to practitioners and public health workers. Functional indices of nutritional status are emerging as an important class of diagnostic tools. Some of these are given in Table 35.
TABLE 35

5. Assessment of dietary intake

The value of nutritional assessment is greatly enhanced when it is supplemented by an assessment of food consumption. Direct assessment of food consumption involves dietary surveys which may be household inquiries or individual food consumption surveys. Well-organized surveys for this purpose are available (130,131).

A diet survey may be carried out by one of the following methods: (i) WEIGHT OF RAW FOODS: This is the method widely employed in India as it is practicable and if properly carried out is considered fairly accurate. The survey team visits the households, weighs all food that is going to be cooked and eaten as well as that which is wasted or discarded. The duration of the survey may vary from 1 to 21 days, but commonly 7 days which is called "one dietary cycle." (ii) WEIGHT OF COOKED FOODS: Foods should preferably be analyzed in the raw in which they are normally consumed, but this method is not easily acceptable among people. (iii) ORAL QUESTIONNAIRE METHOD: This is useful in carrying out a diet survey of a large number of people in a short time. Inquiries are made retrospectively about the nature and quantity of foods eaten during the previous 24 or 48 hours. If properly carried out, oral questionnaire method can give reliable results. A diet survey may also include collection of data relating to dietary habits and practices.

The data that is collected have to be translated into (a) mean intake (grams) of food in terms of cereals, pulses, vegetables, fruits, milk, meat, fish and eggs, and (b) the mean intake of nutrients per adult male value or "consumption unit." This exercise requires the use of suitable tables of food composition. An excellent guide for carrying out this analysis is the Indian Council of Medical Research (ICMR) publication: "Nutritive Value of Indian Foods" (43).

A diet survey provides information about dietary intake patterns, specific foods consumed and estimated nutrient intakes. It indicates relative dietary inadequacies as judged by present standards. Not only will such information be valuable for planning health education activities, but it will also allow an assessment to be made of the extent and nature of changes needed in the agriculture and food production industries.

6. Vital statistics

An analysis of vital statistics – mortality and morbidity data – will identify groups at high risk and indicate the extent of risk to the community. Mortality in the age group 1 to 4 years is particularly related to malnutrition. In developing countries, it may be as much as 20%. It is also common that in countries such as Australia, Denmark or France. The other rates commonly used for this purpose are: infant mortality rate, second-year mortality rate, rate of low birth-weight babies and life expectancy. These rates are influenced by nutritional status and may be closely related to indices of nutritional status. Mortality data, however, do not provide a satisfactory picture of the nutritional status of a population (132).

Data on morbidity (e.g., hospital data or data from community health and nutrition surveys) particularly in relation to problems of an infectious nature, are also very useful in providing additional information contributing to the nutritional status of the community.

7. Assessment of ecological factors

Malnutrition is the end result of many interacting ecological factors. In any nutrition survey it is necessary to collect ecological information of the given community in order to make the nutrition assessment complete. A study of the ecological factors comprise the following: (a) FOOD BALANCE SHEET: This is an indirect method of assessing food consumption, in which supplies are related to census population to derive levels of food consumption in terms of per capita supply availability. The estimate refers to the country as a whole, and so conceals differences which may exist between regions, and among ethnic, age and sex groups. The great advantage of this method is that it is simple and probably simpler than any other method of direct assessment. Used intelligently, this method does give an indication of the general pattern of food consumption in the country. (b) SOCIO-ECONOMIC FACTORS: Food consumption patterns are likely to vary among various socio-economic groups. Family size, occupation, income, education, customs, cultural patterns in relation to feeding practices of children and mothers, all influence food consumption patterns. (c) HEALTH AND EDUCATIONAL SERVICES: Primary health care services, feeding and immunization programmes should also be taken into considerate. (d) CONDITIONING INFLUENCES: These include parasitic, bacterial and viral infections which precipitate malnutrition. It is necessary to make an "ecological diagnosis" of the various factors influencing nutrition in the community before it is possible to put into effect measures for the prevention and control of malnutrition.

NUTRITIONAL SURVEILLANCE

The concept of nutritional surveillance is derived from disease surveillance. Nutritional surveillance has been defined as "Keeping watch over nutrition, in order to make decisions that will lead to improvement in nutrition in population" (133). Three distinct objectives have been defined for surveillance systems: (a) to aid long-term planning in health and development, (b) to provide input for programme management and evaluation, and (c) to give timely warning and intervention to prevent short-term food consumption crises (133, 134).
Nutritional surveillance and growth monitoring

Nutritional surveillance should not be confused with growth monitoring. The differences are shown in Table 36.

Growth monitoring is oriented to the individual child, and is a dynamic measure of its health from month to month. It focuses on normal nutrition and the means to promote continued growth and good health. It requires enrolment of the infant at an early stage, preferably before 6 months. Regular monthly participation is crucial to detect early onset of growth faltering.

Nutritional surveillance, on the other hand, can be carried out on a representative sample of children in the community. It gives a reliable idea of the overall nutritional condition of village (or area) A – whether it is good or bad, is better or worse than that of village B or C (and so requires supplies and personnel), and whether it is improving or deteriorating with time. It can help to diagnose malnutrition and assess the impact of occurrence like drought or measures designed to alleviate malnutrition in the community at large.

**Nutritional status indicators**

Indicators that are considered useful for the surveillance of nutritional status are given in Table 37. There is an increasing trend to use nutritional indicators to measure quality of life, specially as a means of evaluating both development programmes and health programmes. Many of the indicators used in nutritional surveillance are the same as the socio-economic and health status indicators recommended for monitoring progress in health.

**SOCIAL ASPECTS OF NUTRITION**

Food means not only proteins, fats, minerals, vitamins and other nutrients – but much more; it is part of security and civilization. Nations and civilizations are linked together not only by ideas, but also by bread. Hunger and malnutrition are problems everywhere and have harnessed mankind and threatened peace throughout history. It is no wonder that the growing incidence of hunger and malnutrition should have come to the forefront of international concern.

**Problem of malnutrition**

Malnutrition has been defined as “a pathological state resulting from a relative or absolute deficiency or excess of one or more essential nutrients” (1). It comprises four forms – undernutrition, overnutrition, imbalance and the specific deficiency (136). (1) *Undernutrition*: This is the condition which results when insufficient food is eaten over an extended period of time. In extreme cases, it is called starvation. (2) *Overnutrition*: This is the pathological state resulting from the consumption of excessive quantity of food over an extended period of time. The high incidence of obesity, atheroma and diabetes in Western societies is attributed to overnutrition. (3) *Imbalance*: It is the pathological state resulting from a disproportion amongst essential nutrients with or without the absolute deficiency of any nutrient. (4) *Specific deficiency*: It is the pathological state resulting from a relative or absolute lack of an individual nutrient.
We do not know enough about the dimensions of the problem. According to FAO reports, there are about 460 million people – 15 per cent of the world’s population, excluding China – who are malnourished, of which about 300 million live in South Asia where they constitute one-third of the population (137). What makes the situation most serious is that malnourishment’s main victims are children under the age of 15. But children under the age of 5 years are hit the hardest. On a global scale the five principal nutritional deficiency diseases that are being accorded the highest priority are kwashiorkor, marasmus, xerophthalmia, nutritional anaemias and endemic goitre (137). These diseases represent the tip of the “iceberg” of malnutrition; a much larger population are affected by “hidden” malnutrition which is not easy to diagnose.

The effects of malnutrition on the community are both direct and indirect. The direct effects are the occurrence of frank and subclinical nutritional deficiency diseases such as kwashiorkor, marasmus, vitamin and mineral deficiency diseases. The indirect effects are a high morbidity and mortality among young children (nearly 50 per cent of total deaths in the developing countries occur among children under 5 years of age as compared to less than 5 per cent in developed countries), retarded physical and mental growth and development (which may be permanent), lowered vitality of the people leading to lowered productivity and reduced life expectancy. Malnutrition predisposes to infection and to infection to malnutrition; and the morbidity arising therefore as a result of complications from such infectious diseases as tuberculosis and gastro-enteritis is not inconsiderable. The high rate of maternal mortality, stillbirth and low birth-weight are all associated with malnutrition.

In the more developed countries of the world nutritional problems are somewhat different. Overnutrition is encountered much more frequently than undernutrition. The health hazards from overnutrition are a high incidence of obesity, diabetes, hypertension, cardiovascular and renal diseases, disorders of liver and gall bladder. From this brief review, it is obvious that the consequences of malnutrition are ominous.

Ecology of malnutrition

Malnutrition is a man-made disease. It is a disease of human societies. It begins quite commonly in the womb and ends in the grave. The great advantage of looking at malnutrition as a problem in human ecology is that it allows for variety of approaches towards prevention. Jelliffe (1966) (136) listed the ecological factors related to malnutrition as follow: conditioning influences, cultural influences, socio-economic factors, food production and health and other services.

(1) Conditioning influences: Infectious diseases are an important conditioning factor responsible for malnutrition, particularly in small children. Diarrhoea, intestinal parasites, measles, whooping cough, malaria, tuberculosis all contribute to malnutrition. In fact it is a vicious circle – infection contributing to malnutrition; and malnutrition causing an otherwise minor childhood ailments to become killers. It has been shown that where environmental conditions are poor, small children may suffer from some infection or the other for almost half of their first three years of life. The interrelationship between malnutrition and infection has been well documented.

(2) Cultural influences: Lack of food is not the only cause of malnutrition. Too often there is starvation in the midst of plenty. People choose poor diets when good ones are available because of cultural influences which vary widely from country to country, and from region to region. These may be stated as follows: (a) Food habits, customs, beliefs, traditions and attitudes: Food is a symbol of the oldest and most deeply entrenched aspect of any culture. They have deep psychological roots and are associated with love, affection, worship, self image and social prestige. The family plays an important role in shaping the food habits, and these habits are passed from one generation to another. Rice is the staple cereal in the eastern and southern States of India and wheat is the staple cereal in the northern States. During the second World War, when wheat was made available in ample supply in South India, people refused to buy wheat because it was not their staple cereal. The story is told of a Philippine student who died of beriberi after writing an essay on the superiority of rice. In the selection of foods, personal likes and dislikes play an important part. There are several reasons for this. Food taboos which prevent people from consuming nutritious foods even when these are easily available. (c) Food fads: In the selection of foods, personal likes and dislikes play an important part. There are several reasons for this. Food taboos which prevent people from consuming nutritious foods even when these are easily available. (d) Cooking practice: Draining away the rice water at the end of cooking, prolonged boiling in open pans, peeling of vegetables, all influence the nutritive value of foods. (e) Child rearing practices: These vary widely from region to region and influence the nutritional status of infants and children. Examples of this situation are premature curtailment of breast feeding, the adoption of bottle feeding and adoption of commercially produced refined foods. (f) Marrying: In some communities, men eat first and women eat last and poorly. Consequently, the health of women in these societies may be adversely affected. Chronic alcoholism is another factor which may lead to serious malnutrition.

(3) Socio-economic factors: Malnutrition is largely the by-product of poverty, ignorance, insufficient education, lack of knowledge regarding the nutritive value of foods, inadequate sanitary environment, large family size, etc. These factors bear most directly on the quality of life and are the true determinants of malnutrition in society. The speed with which populations are growing in many developing countries is another important factor to reckon with. It has made the solution of the malnutrition problem more difficult. In short the causes of malnutrition are built into the very nature of society, in the socio-economic and political structures, both nationally and internationally (137).
(4) FOOD PRODUCTION: Increased food production should lead to increased food consumption. The average Indian has 0.6 hectare of land surface compared to 5.8 hectare per head in the developed countries. The per capita arable land for an average Indian is only 0.3 hectare (15). Yields per hectare are only about one-fourth of those achieved in the industrialized countries. Given the best technology known at present, most developing countries could increase their food production several fold. But increased food production will not solve the basic problem of hunger and malnutrition in much of the developing world. Scarcity of food, as a fact, remains. The responsibility for malnutrition, may be true at the family level; but it is not true on a global basis, nor is it true for most of the countries where malnutrition is still a serious problem. It is a problem of uneven distribution between the countries and within the countries. It is said that there will be very little malnutrition in India today if all the food available can be equitably distributed in accordance with physiological needs (139).

(5) HEALTH AND OTHER SERVICES: The health sector, if properly organized and given adequate resources can combat malnutrition. Some of the remedial actions that can be taken up by the health sector are: (1) Nutritional surveillance: Nutritional surveillance implies the continuous monitoring in a community, or area of factors or conditions which indicate, relate to, or imply on the nutritional status of individuals or groups of people (WHO, 1976) (140). The first task is to identify the groups and individuals affected -- through clinical examination and simple body measurements of protein-energy malnutrition and hospital records. A further step is to carry out surveys in the villages. The data will give a more realistic picture of the nutritional status of the community. (6) Nutritional rehabilitation: Immediate measures are required as soon as the malnourished subjects are located. Children suffering from severe PEM with complications (e.g. severe dehydration) may be in a hospital. Less severely affected children can be treated at a domiciliary basis or in special nutrition rehabilitation centres. These centres should be linked with health centres. (3) Nutrition supplementation: The target groups are mothers and children. Supplementary feeding is normally regarded as a step-gap measure for the rehabilitation of malnourished children. (4) Health education: It is opined that by appropriate educational action, about 50 per cent of nutritional problems can be solved. Health education programmes in nutrition is often a weak component. Its reinforcement is a key element in all health services development.

Preventive and social measures

Since malnutrition is the outcome of several factors, the problem can be solved only by taking action simultaneously at various levels -- family, community, national and international levels. It requires a coordinated approach of many disciplines -- nutrition, food technology, health administration, health education, marketing, etc. In short, it calls for a comprehensive programme of social development of the entire country.

ACTION AT THE FAMILY LEVEL

The principal target of nutritional improvement in the community is the family, and the instrument for combating malnutrition at the family level is nutrition education. The housewife is the " manager" to the consumption of foods in the family. In some families, the husband determines what foods will reach the table. Both the husband and the wife need to be educated on the selection of right kinds of local foods and in the planning of nutritionally adequate diets within the limits of their purchasing power. Harmful food taboos and dietary prejudices can be identified and corrected. Since food expenditure often amounts to 50–70 per cent of family budgets, nutrition education programmes should be a good investment (141). The promotion of breast-feeding and improvement in infant and child feeding practices are the two areas where nutrition education can have a considerable effect. Action is also needed to counter misleading commercial advertising with regard to baby foods. Attention should also be focused on the nutritional needs of expecting and nursing mothers and children in the family. The shortage of protective foods can be met to some extent by planning a kitchen garden or keeping poultry. Adequate nutrition can be obtained in most countries with a combination of locally available and acceptable foods. Other related activities at the family level are the "package" of mother and child health, family planning and immunization services. The community health workers and the multipurpose workers are the kind of people in key positions to impart nutrition education to the families in their respective areas.

ACTION AT THE COMMUNITY LEVEL

Action at the community level should commence with the analysis of the nutrition problem in terms of (a) the extent, distribution, and types of nutritional deficiencies; (b) the population groups at risk, and (c) the dietary and non- nutritional factors contributing to malnutrition. To obtain this information, diet and nutrition surveys in carefully chosen representative population samples will have to be carried out using standardized methodologies which will permit comparisons in time and space. Having obtained information about the magnitude of the nutrition problem in the community, the next important step will be to plan realistic and feasible approaches to the control of the problem based on local resources. In malnutrition countries such as India, it is usual to start with direct intervention measures such as supplementary feeding programmes, mid-day school meals, vitamin A prophylaxis programme, but these will only provide palliative, partial or temporary solutions. The real permanent solution can only come from fundamental measures that will correct the basic causes of malnutrition. This implies, first of all, increasing the availability of foods both in quantity and quality, but -- much more important -- making sure that the people suffering or at risk of malnutrition can obtain these foods.

The Applied Nutrition Programme is an attempt at production of various types of protective foods by the community for the community. The Integrated Child Development Services (ICDS) Programme makes a concerted and coordinated effort to deliver a basic minimum package consisting of supplementary nutrition, immunization, health check-ups, health and nutrition education for the mothers and non-formal education for the preschool age children. The target groups are children up to six years, pregnant and lactating women, and other women in the age group 15 to 44 years. Significant improvements in the overall living conditions of the people is also called for at the community level. This includes such measures as health
education, improvement of water supply, control of infectious diseases. In brief, a broad socio-economic development of the entire community is called for.

ACTION AT THE NATIONAL LEVEL

The burden of improving the nutritional status of the people of the country is that of the State. The national level in India are: (1) Rural development: The nutritional uplift of people, especially in a country like India, can come about only as part and parcel of an overall socio-economic development of rural areas where 80% per cent of people live. Even an attempt to increase food production will not solve the problem of undernutrition if the income levels of vast sections of the people continue to be so low that they cannot afford to buy the foods they need. It therefore becomes necessary to raise the living standards and purchasing power of the people. This implies a broad-based programme of rural development. (2) Increasing agricultural production: The food production potential is still greatly under-utilized. It must keep pace with population growth. This implies application of modern farming practices, the expansion of cultivated areas, the use of fertilizers, better seeds, and so on. Increased food production is meaningless if not accompanied by an effective food distribution system. This implies marketing, land tenure, and food price policies. Irrigation projects undertaken to increase food production could be counter-productive if parallel measures aimed at prevention of monsoon-breach and other vector control measures are not built into the programmes. (3) Stabilization of population: The population policy in India is related to food and nutrition policy. The accent now is on birth spacing and a small family norm. (4) Nutrition intervention programmes: Several nutritional problems of developing countries today can be mitigated, if not entirely solved by short-term programmes. The prevention and control of endemic goitre through iodized common salt, the control of anaemia through distribution of iron and folic acid tablets to pregnant and nursing mothers, or possibly through fortification of common foods with iron, the control of nutritional blindness through periodic administration of massive oral doses of vitamin A to children at risk; supplementary feeding programmes for preschool children are examples of such measures. These programmes have direct impact on the health and nutritional status of particular segments of the population. These programmes alleviate the situation as a temporary measure. (5) Nutrition related health activities: Several programmes within the field of health, seemingly unrelated to nutrition, may have a profound impact on the nutritional status. The National Maternal Infants Care Programme, by opening up vast tracts of land for cultivation, has made an outstanding contribution to health and nutrition. Since malnutrition is closely related to infection, all programmes of immunization and improvement of environmental sanitation will inevitably have a beneficial effect on nutrition. Programmes of family planning could make a major contribution to the improvement of nutritional status of mothers and children. All these programmes may be considered as alternative approaches to improving the nutritional status of the people. The FAO/WHO Expert Committee on Nutrition. (1976) stressed that food and nutrition planning must be an integral part of the overall socio-economic development.

ACTION AT THE INTERNATIONAL LEVEL

Food and nutrition are global problems, just as health and sickness; and they are interrelated. There is considerable scope for international cooperation in solving the problems of malnutrition. International cooperation can play an important role in mitigating the effects of acute emergencies caused by floods and droughts. The establishment of the multilateral World Food Programme in 1963 to stimulate and promote economic and social development as a means of providing enough safe food to those in need and to come to the aid of victims of emergency is an example of international cooperation. Several international agencies, such as UNICEF, WHO, World Bank, UNDP, and CARE are working in close collaboration helping the rational governments in different parts of the world in their battle against malnutrition.

FOOD SURVEILLANCE

Food surveillance is essential for the protection and maintenance of community health. Broadly it implies the monitoring of food safety/food hygiene. The WHO (145) has defined food safety/food hygiene as "all conditions and measures that are necessary during the production, processing, storage, distribution and preparation of food to ensure that it is safe, sound, wholesome and fit for human consumption." The Declaration of Alma-Ata considered food safety as an essential component of primary health care. The importance of surveillance of foodborne diseases has been underlined in the WHO Sixth General Programme of Work for the period 1978-1983. The most important international programme carrying out activities in the field of food hygiene is the Joint FAO/WHO/FOOD Standard Programme (143).

FOOD HYGIENE

Food is a potential source of infection and is liable to contamination by microorganisms as at any point during its journey from the producer to the consumer. Food hygiene, in its widest sense, implies hygiene in the production, handling, distribution and serving of all types of food (146). The primary aim of food hygiene is to prevent food poisoning and other food-borne illnesses. Food hygiene can be grouped under the following headings.

Milk Hygiene

Source of Infection

Milk is an efficient vehicle for a great variety of disease agents. The sources of infection or contamination of milk may be (1) the dairy animal (2) human handler or (3) the environment, e.g., contaminated vessels, polluted water, flies, dust, etc. (145).

Milkborne diseases

(1) Injections of animals that can be transmitted to man:

Priests' importance:
- Tuberculosis
- Brucellosis
- Streptococcal infections
- Staphylococcal enterotoxin poisoning
- Salmonellosis
- Q fever

Lesser importance:
- Cowpox
- Foot and mouth disease
- Anthrax
- Leptospirosis
- Tick-borne encephalitis.

(2) Infections primary to man that can be transmitted through milk:

- Typhoid and paratyphoid fevers
- Shigellosis
- Cholera
- Enteropathogenic Escherichia coli (EEC)
- Non-diarrhoeal diseases:
  - Streptococcal infections
  - Staphylococcal food poisoning
  - Diphtheria
  - Tuberculosis
  - Enteroviruses
  - Viral hepatitis

Clean and safe milk

The safety and keeping quality of milk are related to its microbial content. The first essential in the production of clean and safe milk, therefore, is a healthy and clean animal. Milk from a healthy udder contains only a few organisms, and these are relatively unimportant. Second, the premises where the animal is housed and milked should be sanitary. The milk vessels must be sterile and kept covered. The water supply must be bacteriologically safe. Milk handling must be free from communicable diseases, and before milking they must wash their hands and arms. Where possible, milking machines must be used. Milk should be cooled immediately to below 10 deg C after it is drawn to retard bacterial growth. In the production of good quality milk, cleanliness of all containers and equipment in which milk is handled is very important.

Methylene blue reduction test: It is an indirect method for detection of microorganisms in milk. The test is carried out on the milk accepted for pasteurization. It is based on the observation that bacterial growing in milk bring about a decrease in the color imparted to milk. In conducting the test, definite quantities of methylene blue are added to 10 ml of milk and the sample is held at a uniform temperature of 37 deg C until the blue color has disappeared. The milk which remains blue the longest is considered to be of the best quality and a scale of grading different milk samples on the basis of the time required to reduce a definite quantity of methylene blue has been worked out. The test thus serves as confirmation of heavy contamination and compared with direct counts of bacteria, it saves time and money.

Pasteurization of milk

Pasteurization may be defined as the heating of milk to such temperatures and for such periods of time as are required to destroy the pathogens that may be present while causing minimal change in the composition, flavor and nutritive value (WHO, 1970; 1946). There are several methods of pasteurization. Three are widely used:

- (1) Holder (Vat) method: In this process, milk is kept at 63-66 deg C for at least 30 minutes, and then quickly cooled to 5 deg C. Vat method is recommended for small and rural communities. In larger cities, it is going out of use.
- (2) HTST method: Also known as "High Temperature and Short Time Method". Milk is rapidly heated to a temperature of nearly 72 deg C, it is held at that temperature for not less than 15 seconds, and then rapidly cooled to 4 deg C. This is now the most widely used method. Very large quantities of milk per hour can be pasteurized by this method.
- (3) UHT Method: Also known as "ultra-high temperature method." Milk is rapidly heated and sterilized in 2 stages (the second stage usually being under pressure) to 125 deg C for a few seconds only, it is then rapidly cooled and bottled as quickly as possible.

Pasteurization is a preventive measure of public health importance and corresponds in all respects to the modern principles of supplying safe milk. Pasteurization kills nearly 90 per cent of the bacteria in milk including the more heat-resistant tubercle bacillus and the Q fever organisms. But it will not kill thermophilic bacteria nor the bacterial spores. Therefore, despite pasteurization, with subsequent rise in temperature, the bacteria are bound to multiply. In order to check the growth of microorganisms, pasteurized milk is rapidly heated, usually in 2 stages, after which it is cooled to 4 deg C. It should be consumed within 24 hours of pasteurization. Hydrogenically produced pasteurized milk has a keeping quality of not more than 8 to 12 hours at 18 deg C.

Tests of pasteurized milk

- (1) Phosphate test: This test is widely used to check the efficiency of pasteurization. The test is based on the fact that raw milk contains an enzyme called phosphatase which is destroyed on heating at a temperature which corresponds closely with the standard time and temperature required for pasteurization. At 60 deg C for 30 minutes phosphate is completely destroyed. Consequently, the test is used to detect inadequate pasteurization or the addition of raw milk.
- (2) Standard plate count: The bacteriological quality of pasteurized milk is determined by the standard plate count.
- (3) Coliform count: Coliform organisms are usually completely destroyed by pasteurization, and therefore, their presence in pasteurized milk is an indication either of improper pasteurization or post-pasteurization contamination. The standard in most countries is that coliforms be absent in 1 ml of milk.

MEAT HYGIENE

The term "meat" includes various tissues of animal origin. The diseases which may be transmitted by eating uncooked meat are: (1) TAPEWORM INFECTIONS: Taenia solium, T. saginata, Trichinella spiralis and Fasciola hepatica. (2) BACTERIAL INFECTIONS: anthrax, actinomycesis, tuberculosis and food poisoning.
MEAT INSPECTION

Animals intended for slaughter are subjected to proper ante mortem and post mortem inspection by qualified veterinary staff. The principal causes of ante-mortem rejection of animals are emaciation, exhaustion, pregnancy, sheep-pox, foot-rot, actinomycosis, brucellosis, leperich conditions, diarrhoea and other diseases of an infectious nature rendering meat unfit for human consumption. The main causes of the post mortem rejection are cysticercus bovis, fasciola hepatica, fascioliasis, tetanus, pseudomembranous and nodular infections of liver and lungs, tuberculosis, cysticercus cellulose, etc. (147). The characteristics of good meat are that it should be neither pale pink nor a deep purple tint, firm and elastic to touch, should not be slimy and have an agreeable odour.

SLAUGHTER HOUSES

Slaughter houses are the places where animals, whose flesh is intended for human consumption, are killed. The hygiene of the slaughter house is of paramount importance to prevent the contamination of meat during the process of dressing. The following minimum standards for slaughter houses have been suggested under the Model Public Health Act (1952) in India (148). (1) Location: Preferably away from residential areas. (2) Structure: Floors and walls up to 3 feet should be impervious and easy to clean. (3) Disposal of wastes: Blood, offal, etc. should not be discharged into public sewers but should be collected separately. (4) Water supply: Should be independent, adequate and continuous. (5) Examination of animals: Ante mortem and post mortem examination to be arranged. Animals or meat found unfit for human consumption should be destroyed or denatured. (6) Storage of meat: Meat should be stored in fly-proof and rat-proof rooms; for overnight storage, the temperature of the room shall be maintained below 5 deg C. (7) Transportation of meat: Meat shall be transported in fly-proof covered vans. (8) Miscellaneous: Animals other than those to be slaughtered should not be allowed inside the shed.

FISH

Fish deteriorates or loses its freshness because of autolysis which sets in after death and because of the bacteria with which they become infected. Stale fish should be condemned. The signs of fresh fish are: (1) it is in a state of stiffness or rigor mortis. (2) The scales are bright red, and (3) the eyes are clear and prominent.

Fish is the intermediate host of the tape worm. Diphyllobothrium latum. This cestode is communicable to man, but is very rarely encountered. Sewage, bacteria and viruses (e.g. the virus of hepatitis A type) may be concentrated in shellfish such as oysters, and fish may carry Vibrio parahemolyticus. Salmonella spp., Cladistium butulmimum type E, and other organisms (149). Consumption of certain fish may sometimes give rise to fish poisoning'.

TNINED FISH: When called upon to inspect tinned fish (or meat or any food), the following points should be noted: the tin must be new and clean without leakages or rusting; there should be no evidence of having been tempered with such sealed openings; on opening the tin, the contents should not be blown out which indicates decomposition.

EGG

Although the majority of freshly laid eggs are sterile inside, the shells become contaminated by jaeel material from the hen. Microorganisms including pathogenic Salmonella can penetrate a cracked shell and enter the egg (149).

FRUITS AND VEGETABLES

Fruits and vegetables constitute another important source for the spread of pathogenic organisms, protozoans and helminths. These infections are a serious menace to public health where sewage is used for growing vegetables. The vegetables which are consumed raw in the form of salad pose a problem in food sanitation. People should be educated to wash the vegetables before eating them raw. Vegetables which are cooked are free from this danger.

SANITATION OF EATING PLACES

Sanitation of eating establishments is a challenging problem in food sanitation. The following minimum standards have been suggested for Restaurants and Eating Houses in India under the Model Public Health Act (1952) (148). (1) Location: Shall not be near any accumulation of rubbish or garbage, stable, manure pit and other sources of nuisance. (2) Floors: To be higher than the adjoining land, made with impervious material and easy to keep clean. (3) Rooms: (a) Rooms where meals are served shall not be less than 100 sq. ft. and shall provide accommodation for a maximum of 10 persons. (b) Walls up to 3 feet should be smooth, corners to be rounded; should be inerous and easily washable. (c) Lighting and ventilation – ample natural lighting facilities aided by artificial lighting with good circulation of air are necessary. (4) Kitchen: (5) Fridge space minimum 60 sq. ft. (6) Window opening to be 25 per cent of floor area. (7) Floor to be impervious, smooth, easy to keep clean and non-slippery. (8) Doors and windows to be rust-proof, fly-proof, and of the self-closing type. (9) Ventilation 2 per cent of the floor area in addition to smoke pipes. (10) Storage of cooked food: Separate room to be provided. For long storage, control of temperature is necessary. (11) Storage of uncooked foodstuffs: Perishable and non-perishable articles to be kept separately, in rat-proof and vermin-proof space; for storage of perishable articles temperature control should be adopted. (12) Furniture: Should be reasonably strong and easy to keep clean and dry. (13) Disposal of refuse: To be collected in covered, impervious bins and disposed off twice a day. (14) Water supply: To be an independent source, adequate, continuous and safe. (15) Sanitary facilities: To be provided. Cleaning of utensils and crockery to be done in hot water and followed by disinfection.

FOOD HANDLERS

Food sanitation rests directly upon the state of personal hygiene and habits of the persons working in the food establishments. Proper handling of foods, utensils and dishes together with emphasis upon the necessity for good personal hygiene are of great importance. The infections which are likely to be transmitted by the food handlers are diarrhoea, dysenteries, typhoid and paratyphoid fevers, enteroviruses, viral hepatitis, prozone cysts, eggs of nematodes, strepto and staphylococcal infections, and salmonellosis.
The first essential is to have complete medical examination carried out for all food handlers at the time of employment. Any person with a history of typhoid fever, diphtheria, chronic dysentery, tuberculosis or any other communicable disease should not be employed. Persons with wounds, cutis media or skin infections should not be permitted to handle food or utensils. The day to day health appraisal of the food handlers is also very important, those who are ill should be excluded from food handling. It is also important that any illness which occurs in a food handler's family should be once noted.

Education of food handlers in matters of personal hygiene, food handling, utensils, dish washing, and insect and rodent control is the best means of promoting food hygiene. Most of the food handlers have little educational background. Certain aspects of personal hygiene are therefore required to be continually impressed upon them:
(a) Hands: The hands should be cleaned at all times. Hands should be scrubbed and washed with soap immediately after visiting a lavatory and as often as necessary at other times. Finger nails should be kept trimmed and free from dirt.
(b) Hair: Hair covering should be provided, particularly in the case of females to prevent loose hair entering the food-stuffs.
(c) Overall: Clean white overalls should be worn by all food handlers.
(d) Habits: Coughing and sneezing in the vicinity of food, licking the fingers before picking up an article of food, smoking on food premises are to be avoided.

FOOD-BORNE DISEASES

The term "food-borne disease" is defined as: "A disease, usually either infectious or toxic in nature, caused by agents that enter the body through the ingestion of food." With the increase in urbanization, industrialization, tourism and mass catering systems, food-borne diseases are on the increase throughout the world. Food-borne diseases may be classified as:

A. Food-born intoxications
1. Due to naturally occurring toxins in some foods (159)
   a. Amygdalin (bitter almond) and potato glycoalkaloids.
   b. Endemic acidos (Pyrolidine alkaoids).
2. Due to toxins produced by certain bacteria (130, 151)
   a. Botulism
   b. Staphylococcus poisons
3. Due to toxins produced by some fungi (149, 152)
   a. Aflatoxin
   b. Ergot
   c. Fusarium toxins
4. Food-borne chemical poisoning (158, 154)
   a. Heavy metals, e.g., mercury (usually in fish), cadmium (in certain shellfish) and lead (in canned food)
   b. Oils, petroleum derivatives and solvents (e.g., trichloroethylene)
   c. Migrani chemicals from package materials
   d. Asbestos
   e. Pesticide residues (DDT, BHC).

B. Food-borne infections

Group
(1) Bacterial diseases
   Examples of illness in each group
   a. Typhoid fever
   b. Paratyphoid fever
   c. Salmonellosis
   d. Staphylococcal intoxication
   e. Clostridium botulinum
   f. E.coli diarrhea
   g. Non-cholera vibrio illness
(2) Viral diseases
   a. Hepatitis
   b. Gastroenteritis
(3) Parasites
   a. Taenia hydatidosis
   b. Ascarisis
   c. Anoebiosis

FOOD TOXICANTS

1. Neurolythiasis
   The cause of neurolythiasis is a toxin, Beta-nitro amino alanine (BNA) which is found in the seeds of the pulse, L.ciceria (Rheeni dhal). Neurolythiasis is a public health problem in certain parts of the country where this pulse is eaten (see page 64).

2. Aflatoxins (155, 156)
   Aflatoxins are a group of mycotoxins produced by certain fungi, Aspergillus flavus and A. parasiticus. These fungi infect foodgrains such as groundnut, maize, parboiled rice, sorghum, wheat, rice, cotton seed and tapioca under conditions of improper storage, and produce aflatoxins of which B1 and G1 are the most potent hepatotoxins, in addition to being carcinogenic. The most important factors affecting the formation of the toxin are moisture and temperature. Moisture levels above 15 per cent and temperature ranging from 11 to 37°C favour toxin formation. Aflatoxins is a quite a public health problem in India. The latest report (1975) of 400 cases of aflatoxin poisoning including 100 deaths from Banswada and Ponchrmahal district of Rajastan and Gujarat respectively highlight the problem in India. Aflatoxin B1, has also been detected in samples of breast milk and urine collected from children suffering from infantile cirrhosis. Attempts are also being made to relate aflatoxin with human liver cirrhosis.

Control and preventive measures: A crucial factor in the prevention of fungal contamination of foodgrains is to ensure their proper storage after drying. Moisture content should be kept below 10 per cent. If the food is contaminated, it must not be consumed. It is also essential to educate the local population on the health hazards of consuming contaminated foodgrains.

3. Ergot (157, 158)
   Unlike Aspergillus, ergot is not a storage fungus, but a field fungus. Foodgrains such as lalita, rye, sorghum, and wheat have a tendency to get infested during the flowering stages by the ergot fungus (Claviceps purpurea). Fungus grows as a blackish mass and the seeds become black and irregular and are harvested along with food grains. Consumption of ergot infected grain leads to ergotism. Sporadically outbreaks of ergot poisoning in human population have been reported from time to time in areas where bajas is consumed as a staple. The symptoms are acute but rarely
fatal and include nausea, repeated vomiting, giddiness and drowsiness extending sometimes for periods up to 48 hours after the ingestion of ergot grains. In chronic cases, painful cramps in limbs and peripheral gangrene due to vasoconstriction of capillaries have been reported. However, the long-term effect of consuming small amounts of the toxin are not known. A disquieting feature is that the recently introduced high-yielding varieties of bari are more susceptible to ergot infection. Ergot-infected grains can be easily removed by flotation; this in 20 per cent salt water. They can also be removed by hand-picking or air flotation. The upper limit for the ergot alkaloids has been estimated to be 0.05 mg per 100 grams of the food material.

4. Epidemic dropsy (159, 144)

From time to time, outbreaks of "epidemic dropsy" are reported in India. The cause of epidemic dropsy was not known until 1926, when Sarkar ascribed it to the contamination of mustard oil with argemone oil. Lal and Roy (1937) and Chopra et al., (1939) gave experimental proof of the cause of epidemic dropsy. Mukherji et al., (1941) isolated a toxic alkaloid, sangumuridine from argemone oil and found out its chemical formula. This toxic substance interferes with the oxidation of pyruvic acid which accumulates in the blood.

The symptoms of epidemic dropsy consist of sudden, non-inflammary, bilateral swelling of legs, often associated with diarrhoea. Dyspnoea, cardiac failure and death may follow. Some patients may develop glaucoma. The disease may occur at all ages, except breast-fed infants. The mortality varies from 5–50 per cent.

The contamination of mustard or other oils with argemone oil may be accidental or deliberate. Seeds of Argemone mexicana (prickly poppy) closely resemble mustard seeds. The plant grows wild in India. It has prickly leaves and bright yellow flowers. Crops of mustard are gathered during March, and during this period, the seeds of argemone also mature and are likely to be harvested along with the mustard. This necessitates that unscrupulous dealers mix argemone oil with mustard or other oils.

Argemone oil is orange in colour with an acrid odour. The following tests may be applied for the detection of argemone oil: (1) Nitric acid test: A simple test is to add nitric acid to the sample of oil in a test tube. The test tube is shaken and the development of a brown to orange-red colour shows the presence of argemone oil. The nitric acid test is positive only when the level of argemone oil is about 0.25 per cent (160). (2) Paper chromatography test: This is the most sensitive test yet devised. It can detect argemone oil up to 0.0001 per cent in all edible oils and fats.

The accidental contamination of mustard seeds can be prevented at the source by removing the argemone seeds growing among oil-seed crops. Unscrupulous dealers may be dealt with by the strict enforcement of the Prevention of Food Adulteration Act.

5. Endemic ascites (161, 162)

In Hassani Block of Sarguja district in Madhya Pradesh, during 1973 and again during 1976, an outbreak of rapidly developing ascites and jaundice was reported among the Nageia tribe. Both the sexes and all the age groups, except infants, were affected. The overall mortality was 40 per cent.

Studies conducted by the National Institute of Nutrition, Hyderabad showed that the local population subsist on the millet Paniicum miliare (locally known as Gondilli) which gets contaminated with weed seeds of Crotalaria (locally known as jhumunia). On chemical analysis, Jhumunia seeds were found to contain pyrrolizidine alkaloids which are hepatotoxic.

The preventive measures comprise educating the people in the affected areas about the disease, deseeding of the Jhumunia plants which grow along with the staple, and simple sieving of the millet at the household level to remove the seeds of Jhumunia which are considerably smaller than those of the millet.

6. Fusarium toxins (163)

Fusarium species of field fungi are known to contaminate food crops and pose health hazards to livestock and man. The problem of fusarium contamination of sorghum is believed to be on the increase. Rice is also known to be a good substrate for fusarium. Work is now in progress at the National Institute of Nutrition to isolate, and identify the toxic metabolites produced by fusarium inornatum.

Food additives

The concept of adding "non-food" substances to food products is not new. Pickling is an ancient culinary practice aimed at preserving food articles such as mango, lime, etc for fairly long periods by the addition of salt and spices. Modern science of food technology has revolutionized food processing with the introduction of chemical additives to increase the shelf-life of food, improve its taste, and to change its texture or colour. Majority of the processed foods such as bread, biscuits, cakes, sweets, confectionary, jams, jellies, soft drinks, ice creams, ketchup and refined oils contain food additives.

Food additives are defined as non-nutritious substances which are added intentionally to food, generally in small quantity, to improve its appearance, flavour, texture or storage properties (164). This definition also includes animal food adjuncts which may result in residues in human food and components of packaging materials which may find their way into food (165).

Food additives may be classified into two categories: Additives of the first category include colouring agents (e.g., saffron, turmeric), flavouring agents (e.g., vanilla essence), sweeteners (e.g., saccharin), preservatives (e.g., sorbic acid, sodium benzoate), acidity imparting agents (e.g., citric acid, acetic acid), etc (166). These agents are generally considered safe for human consumption. Additives of the second category are, strictly speaking, contaminants incidental through packing, processing steps, farming practices (insecticides) or other environmental conditions (167). Uncontrolled or indiscriminate use of food additives may pose health hazards to food consumers. For example, certain preservatives such as nitrates and nitrates can lead to the production of toxic substances, e.g., nitrosamines that have been implicated in cancer aetiology.

The use of food additives is subjected to government regulations throughout the world. In India two regulations (viz. the Prevention of Food Adulteration Act and the Fruit Products Order) govern the rules and regulations of food additives (167). Any food that contains food additives that
Food adulteration practices vary from one part of the country to another, and from time to time. Our knowledge about the current practices of food adulteration is by no means complete. Table 38 shows the types of adulteration seen in India (168).

Prevention of Food Adulteration Act, 1954

Enacted by the Indian Parliament in 1954, with the objective of ensuring pure and wholesome food to the consumers and to protect them from fraudulent and deceptive trade practices, the Prevention of Food Adulteration (PFA) Act was amended in 1964, 1976 and lately in 1986 to make the Act more stringent. A minimum imprisonment of 6 months with a minimum fine of Rs. 1,000 is envisaged under the Act for cases of proven adulteration, whereas for the cases of adulteration which may under the food injurious to cause death or such harm which may amount to grievous hurt (within the meaning of section 320 of IPC,) the punishment may go up to life imprisonment and a fine which shall not be less than Rs. 5,000. With the amendment in 1986, the consumer and the voluntary organizations have been empowered under the Act to take samples of food.

Rules are framed which are revised from time to time by an expert body called the "Central Committee for Food standards" which is constituted by the Central Government under the provisions of the Act. Any food that does not conform to the minimum standards is said to be adulterated. Although it is a Central Act, its implementation is largely carried out by the State Governments and local bodies in their respective areas. However, the Centre plays a vital role in proper coordination, monitoring and surveillance of the programme throughout the country. A chain of food laboratories and four regional central Central Food Laboratories (Kolkata, Mumbai, Ghaziabad and Pune) whose report is considered to be final have been established.
Training being an important component of the programme for prevention of food adulteration, the Directorate General of Health Services organizes in-service training programme for different functionaries responsible for implementation of the PFA Act. Food inspectors, analysts and the senior officers concerned with the implementation of the Act in States are provided training.

Food adulteration is a social evil. The general public, traders, and Food Inspectors are all responsible for perpetuating this evil – the public, because of lack of awareness of the dangers of adulteration and their general dishonesty; the traders, for their greed for money; and Food inspectors who find food adulteration a fertile ground to make easy money. Unless the public rises up against the traders and unscrupulous food inspectors, this evil cannot be curbed. It is here the voluntary agencies and consumer guidance societies can play a vital role.

Food standards

(a) CODEX ALIMENTARIUS: The Codex Alimentarius Commission, which is the principal organ of the joint FAO/WHO Food Standards Programme formulates food standards for international market. The food standards in India are based on the standards of the codex alimentarius.

(b) PFA STANDARDS: Under the Prevention of Food Adulteration Act (1954) standards have been established which are revised from time to time by the “Central Committee for Food Standards”. The purpose of the PFA standards is to obtain a minimum level of quality of foodstuffs available under Indian conditions. (c) THE AGMARK STANDARDS: These standards are set by the Directorate of Marketing and Inspection of the Government of India. The Agmark gives the consumer an assurance of quality in accordance with the standards laid down.

(d) BUREAU OF INDIAN STANDARDS: The ISI mark on any article of food is a guarantee of good quality in accordance with the standards prescribed by the Bureau of Indian Standards for that commodity. The Agmark and ISI standards are not mandatory; they are purely voluntary. They express degrees of excellence above PFA standards.

National Nutrition Policy 1993 (169)

Inspite of the significant improvement in food production and advancement in science since independence, under-nutrition continues to be a widespread problem in India. In the year 1993, Govt. of India announced National Nutrition Policy 1992. As nutrition is a multi-sectoral issue, it needs to be tackled at various levels through direct mention interventions for specifically vulnerable groups as well as through various development policy instruments which will create conditions for improved nutrition. The strategy consists of the following:

A. Direct intervention — Short-term

1. Nutritional interventions for specific vulnerable groups.
   a. Expanding the Safety Net - The universal immunisation programme, oral rehydration therapy and the integrated child development services have a considerable impact on child survival and extreme forms of malnutrition.
   b. Improving growth monitoring between age group 0 to 3 years, with closer involvement of the mothers.
   c. Reaching the adolescent girls through ICDS so as to make them ready for safe motherhood.

2. Fortification of essential foods.

3. Popularization of low cost nutritious food.

4. Control of micro-nutrient deficiencies among vulnerable groups.

B. Indirect Policy Instruments: Long-term institutional and structural changes

1. Food security - In order to ensure aggregate food security, a per capita availability of 245 kg/person/year of food grain needs to be attained.

2. Improvement of dietary pattern through production and distribution.

3. Improving the purchasing power of the urban and rural poor and improving the public food distribution system.

4. Land reforms.

5. Health and family welfare.

6. Basic health and nutrition knowledge.

10. Research into various aspects of nutrition, both on the consumption side and the supply side.

11. Equal remuneration for women.

12. Communication through established media for the implementation of nutrition policy.

13. Minimum wage administration.

15. Education and literacy particularly that of women.

16. Improvement of the status of women.

COMMUNITY NUTRITION PROGRAMMES

The Government of India have initiated several large-scale supplementary feeding programmes, and programmes aimed at overcoming specific deficiency diseases through various Ministries to combat malnutrition. They are as shown in Table 39.

1. Vitamin A prophylaxis programme

One of the components of the National Programme for Control of Blindness is to administer a single massive dose of vitamin A containing 200,000 IU (110 mg of retinyl acetate) weekly to all preschool children in the community every 6 months through peripheral health workers. The programme was launched by the Ministry of Health and Family Welfare in 1970 on the basis of technology developed at the National Institute of Nutrition at Hyderabad. An evaluation of the programme has revealed a significant reduction in vitamin A deficiency in children (see page 615, 616 for details).

2. Prophylaxis against nutritional anaemia

In view of its public health importance, a national programme for the prevention of nutritional anaemia was launched by the Govt. of India during the fourth Five Year Plan. The programme consists of distribution of iron and folic acid (foli-fer) tablets to pregnant women and young children (1–12 years). Mother and Child Health (MCH) Centres in urban areas, primary health centres in rural areas, and ICDS projects are engaged in the implementation of this programme. The technology for the control of anaemia through iron fortification of common salt has also been developed at the National Institute of Nutrition at Hyderabad (see page 642 for more details).

3. Control of iodine deficiency disorders

The National Goitre Control Programme was launched by the Government of India in 1962 in the conventional goitre belt in the Himalayan region with the objective of identification of the goitre endemic areas to supply iodized salt in place of common salt and to assess the impact of goitre control measures over a period of time.

Surveys, however, indicated that the problem of goitre and iodine deficiency disorders was more widespread than it was thought earlier, with nearly 145 million people estimated to be living in known goitre endemic areas of the country. As a result, a major national programme – the IDD Control Programme – was mounted in 1986 with the objective to replace the entire edible salt by iodized salt, in a phased manner by 1992 (see page 643 for more details).

4. Special nutrition programme

This programme was started in 1970 for the nutritional benefit of children below 4 years of age, pregnant and nursing mothers and is in operation in urban slums, tribal areas and backward rural areas. The supplementary food supplies about 300 kcal and 10–12 grams of protein per child per day. The beneficiary mothers receive daily 500 kcal and 25 grams of protein. This supplement is provided to them for about 300 days in a year. This programme was originally launched as a Central programme and was transferred to the State sector in the fifth Five Year Plan as part of the Minimum Needs Programme (170). The main aim of the Special Nutrition Programme is to improve the nutritional status of the target groups. This programme is gradually being merged into the ICDS programme.

5. Balwadi nutrition programme

This programme was started in 1970 for the benefit of children in the age group 3–6 years in rural areas. It is under the overall charge of the Department of Social Welfare. Four national level organizations including the Indian Council of Child Welfare are given grants to implement the programme. Voluntary organizations which receive the funds are actively involved in the day-to-day management. The programme is implemented through Balwadis which also provide primary education to these children. The food supplement provides 350 kcal and 10 grams of protein per child per day. Services are being phased out because of universalization of ICDS.

6. ICDS programme

Integrated Child Development Services (ICDS) programme was started in 1975 in pursuance of the National Policy for Children. There is a strong nutrition component in this programme in the form of supplementary nutrition, vitamin A prophylaxis and iron and folic acid distribution. The beneficiaries are preschool children below 6 years, and adolescent girls 11 to 18 years, pregnant and lactating mothers. The States and Union Territories are encouraged to undertake additional ICDS projects on the Central pattern to cover more beneficiaries (170).

The workers at the village level who deliver the services are called Anganwadi workers. Each Anganwadi unit covers a population of about 1000. A network of Mahila Mandalas has been built up in ICDS Project areas to help Anganwadi workers in providing health and nutrition services. The work of Anganwadis is supervised by Mukhyaswaraks. Field supervision is done by the Child Development Project Office (CDPO).

7. Mid-day meal programme

The mid-day meal programme (MDMP) is also known as School Lunch Programme. This programme has been in operation since 1961 throughout the country. The major objective of the programme is to attract more children for admission to schools and retain them so that literacy improvement of children could be brought about (169).

In formulating mid-day meals for school children, the following broad principles should be kept in mind (171).

(a) the meal should be a supplement and not a substitute to the home diet
(b) the meal should supply at least one-third of the total energy requirement, and half of the protein need
(c) the cost of the meal should be reasonably low
(d) the meal should be such that it can be prepared easily in schools; no complicated cooking process should be involved
(e) as far as possible, locally available foods should be used; this will reduce the cost of the meal, and
(f) the menu should be frequently changed to avoid monotony.

MODEL MENU

A model menu for a mid-day school meal is given in Table 40.
The National Institute of Nutrition, Hyderabad has prepared model recipes for the preparation of school meals suitable for North and South. Children of ages of these publications can be had gratis. The National Institute of Nutrition is of the view that the minimum number of feeding days in a year should be 250 to have the desired impact on the children (172).

School feeding should not be considered as an end in itself. The important goals to be accomplished are: reorientation of eating habits; incorporating nutrition education into the curriculum; encouraging the use of local commodities; improving school attendance as well as educational performance of the pupils. Since the number to be fed are in millions, the problem is one of balance between the resources and the number to be fed.

The mid-day meal programme became part of the Minimum Needs Programme in the Fifth Five Year Plan (170).

8. Mid-day meal scheme (173)

Mid-day meal scheme is also known as National Programme of Nutritional Support to Primary Education. It was launched as a centrally sponsored scheme on 15th August 1995 and revised in 2004. Its objective being universalization of primary education by increasing enrolment, retention and attendance and simultaneously impacting on nutrition of students in primary classes. It was implemented in 2,408 blocks in the first year and covered the whole country in a phased manner by 1997-98. The programme, originally covering children of pre-school age (classes 1 to 5) in government, local body and government aided schools and was extended in Oct. 2002, to cover children studying in Education Guarantee Scheme and Alternative and Innovative Education Centres also.

The central assistance provided to states under the programme is by way of free supply of food grain from nearest Food Corporation of India godown at the rate of 100 g. per student per day and subsidy for transport of food grain. To achieve the objective, a cooked mid-day meal with minimum 300 Calories and 8 to 12 grammes of protein content will be provided to all the children in class I to V.

Some suggestions for preparation of nutritious and economical mid-day meals are as under:

- Foodgrains must be stored in a place away from moisture, in airtight containers/bins to avoid infestation.
- Use whole wheat or broken wheat (dalia) for preparing mid-day meals.
- Rice should preferably be parboiled or unpolished.
- "Single Dish Meals" using broken wheat or rice and incorporating some amount of a pulse or soyabean, a seasonal vegetable/green leafy vegetable, and some amount of edible oil will save both time and fuel besides being nutritious. Broken wheat pulao, leafy khichari, spina, dal-vegetable bhaat are some examples of single dish meals.
- Cereal pulse combination is necessary to have good quality protein. The cereal pulse ratio could range from 3:1 to 5:1.
- Sprouted pulses have more nutrients and should be incorporated in single dish meals.
- Leafy vegetables when added to any preparation should be thoroughly washed before cooking and should not be subjected to washing after cutting.
- Soaking of rice, dal, bengal gram etc. reduces cooking time. Wash the grains thoroughly and soak in just sufficient amount of water required for cooking.
- Rice water if left after cooking should be mixed with dal if these are cooked separately and should never be thrown away.
- Fermentation improves nutritive value. Preparation of idli, dosa, dhokla etc. may be encouraged.
- Cooling must be done with the lid on to avoid loss of nutrients.
- Over-cooking should be avoided.
- Reheating of oil used for frying is harmful and should be avoided.
- Leafy tops of carrot, radish, turnips etc. should not be thrown but utilized in preparing mid-day meals.
- Only "polished salt" should be used for cooking mid-day meals.  

Monitoring and evaluation of nutrition programmes

Good preventive medicine demands effective planning, monitoring and evaluation of health programmes. An important advance in this field is the development of the randomized controlled trial for the evaluation of the effectiveness and efficiency of health care programmes.

Criticism is often voiced that nutrition programmes are not based on good intentions. It is considered unethical to launch a major nutritional programme (or for that matter any other health programme) without a built-in-provision for monitoring, evaluation and feedback. Since health and nutrition of the young child is indivisible from the health and nutrition of the family as a whole, there is now increasing recognition that it is only through an improvement of the family diet as a whole, that the diet of the young child in the poor family can be improved (174). Secondly, a question is raised: How long will a country be able to feed its children who may number 100 million or more without any socio-economic improvements? An eminent nutrition scientist in India has said: "In the long run, we can hope to improve the nutritional status of our children only through improvements in the economic conditions of the community to a level at which families can afford balanced diets. Organized State-sponsored feeding programmes cannot be the permanent answer to the problem" (85).

ANNEXURE-5

Exercise and physical activity

Individuals over the age of 20 years should undertake a minimum of 30 minutes of physical activity of moderate intensity (such as walking 5-6 km/hr) on most, if not all days of the week. Greater health benefits can be obtained by engaging in physical activity of longer duration or more vigorous intensity (such as jogging, running, cycling and swimming).

Sedentary people embarking on a physical activity programme should undertake a moderate intensity activity of short duration to start with and gradually increase the duration or intensity. Other day-to-day activities like walking, housework, gardening, will be beneficial not only in weight reduction but also for lowering of blood pressure and serum triglycerides. This also elevates HDL (good) cholesterol in blood. Simple modifications in lifestyle like deliberately climbing up the stairs instead of using the lift and walking for short distance instead of using a vehicle could also immensely help in increasing our physical activity.

Exercise programme should include ‘warm up’ and ‘cool down’ periods each lasting for 5 minutes. During exercise, the intensity of exercise should ensure 60-70% increase in heart rate.

Previously inactive men over the age of 20 years, women over the age of 50 years and people at high risk for chronic diseases like heart disease and diabetes should first consult a physician before engaging in a programme of vigorous physical activity such as running and swimming.

*Energy expenditure on various physical activities (kcal/hr)

</tbody>
</table>

This is calculated as: total fat – saturated fatty acids + polyunsaturated fatty acids – trans fatty acids.

b The percentage of total energy available after taking into account that consumed as protein and fat, will widen the range.

c The term "free sugars" refers to all monosaccharides and disaccharides added to foods by the manufacturer, cook or consumer, plus sugar naturally present in honey, syrup and fruit juices.

d The suggested range should be seen in the light of the Joint WHO/FAO/UNU Expert Consultation on Protein and Amino Acid Requirements in Human Nutrition, held in Geneva from 9 to 16 April 2002.

e Salt should be iodized appropriately. The need to adjust salt iodization, depending on observed sodium intake and surveillance of iodine status of the population, should be recognized.

The term "social sciences" refers to a composite of several disciplines. These disciplines are anthropology, economics, political science, psychology, sociology etc. In general, these disciplines contribute to our understanding of society and human behaviour. The social sciences relevant to medicine are psychology and sociology. They should be considered like anatomy and physiology, the basic sciences of medicine.

Social context of medicine

Health cannot be isolated from its social context. The last few decades have shown that social and economic factors have as much influence on health as medical interventions. All these factors have a direct bearing on the incidence, course and outcome of a wide variety of communicable and non-communicable diseases as well as on many other health problems besetting the world today. They also have an important effect on the provision of health care to all strata of society (1). Poverty, malnutrition, poor sanitation, lack of education, inadequate housing, unemployment, poor working conditions, cultural and behavioural factors all predispose to ill-health. Today more than ever before, there has been an increasing recognition that successful application of medicine to individuals and groups involves more than mere scientific or biological knowledge; it involves an understanding of the behaviour of individuals and groups who live together and also share certain values of life. Man is a social animal. The patient is no longer considered as one who is under strict laboratory control, but an individual with personal idiosyncrasies, erratic habits, customs and beliefs reacting on his body and mind. It has been aptly said that even a person with a broken leg may present complex social and personal factors which may influence his recovery. Thus there has been a shift from the earlier concept of visualising disease in terms of a specific germ to the involvement of "multiple factors" in the causation of disease. Good doctors are being identified as those who treat people, and not only those who treat cases. As a result of this new outlook, concepts of sociology are increasingly being used in the study of disease in human societies.

How much effect social changes might have on health of the people is shown in Fig. 1.

It suggests that health is influenced by four sets of variables—individual predispositions, ecological predispositions, current circumstances, and opportunities. These variables are in turn influenced by the major sources of social changes: economic, political, educational and other systems. The health status of the people can feed back into and influence factors relating to social structure which may in turn influence the predisposing variables, and therefore health (2).

Medicine and the social sciences are concerned, in their own special way, with human behaviour. Specialists in community health, clinical medicine, epidemiology are all seeking the cooperation and help of social scientists in understanding problems such as the social component of health and disease, "illness behaviour" of people, efficient use of medical care and the study of medical institutions. A brief sketch of the current interest of these disciplines in social science is given below:

1. COMMUNITY HEALTH

Community health workers are often faced with the problem of why people who need a particular service are least likely to use it or fail to secure the total benefit which is expected. A case in point is immunisation against communicable diseases. Although, there is a wide range of prophylactic vaccines, immunisation has not gained universal acceptance. The family planning programme in India is a recent example of a health service of which people are not making use to the extent desired. Similarly, health programmes relating to mother and child health care services, improvement of water supplies, installation of sanitary latrines, improvement of dietary patterns and infant rearing practices have all proved abortive or only partially successful. The resistance of the people is felt not only in the field of community health, but in fact even in fields designed to improve their general standard of living. The central question in community health is: Why do people behave as they do? This is the basic problem which the social scientists are studying in India, and are often asked to explain this failure of health measures. In the western countries, social scientists are working on problems of mental health, hospital organization, social class difference in disease, rehabilitation, and professional roles and relationships. In industries, the social scientists are invited to look into the relationships between members of a team who are concerned with doing a job in order to improve the overall performance of the work team. In short, the social scientists are stepping in increasing numbers into the field of community health. The theme common to community health and social sciences is human behaviour. Many community health problems in essence are social problems, and vice versa.

2. CLINICAL MEDICINE

During the past half century, the scientific content of medicine has increased enormously. The acute
Communicable diseases have been brought under control, and good medical care is available to more people than ever before. This has brought to a sharp focus, the so-called “modern diseases” such as cardiovascular disease, cancer, diabetes and mental illness. These diseases have defined “cure” and prevention, and are currently the major causes of morbidity and mortality in developed societies. The clinicians also tend to believe that “psychophysiological stress reactions” are involved in cases of rheumatoid arthritis, obesity, ulceration of intestine, skin diseases, constipation, diarrhoea and epilepsy. It has become apparent that control of these diseases involves not merely medical care but basic changes in the behaviour and habits of the patients, which is one of the frontiers of specialization of social scientists. The social scientists are asking to investigate the life situations of the patients with a view to discover linkages between specific life situations and specific types and causes of illness.

The clinicians have also shown interest in what is known as “illness behaviour” of patients, i.e., why different people react in different ways to the same disease process or regimen of treatment. It is not known why some people (whether by reason of education, religion, social class difference or occupational status) make light of symptoms and some seep into an exaggerated manner, to the slightest pain or discomfort. This is an important area of medical sociology. The doctor-patient relationship, patient care management, hospital organization, collusion of medical treatment and cultural practices are all current interests of medical sociology.

Criticism is often voiced that the present medical sciences (e.g., anatomy, physiology, microbiology, pathology) are insufficient to train the physician to cope with the sociocultural aspects of medicine. It is recognized that the physician needs two kinds of knowledge - medical knowledge and social knowledge, so that he could more effectively serve the patient and the community. Hence is the current interest of medical men in social sciences.

3. EPIEMIOLOGY

Epidemiologists have also forged a close alliance with social scientists in studying the distribution of health and disease in human population, and of factors that cause the distribution. Disease is studied in relationship to factors such as social status, income, occupation, housing, overcrowding, social customs, habits and behaviour. Examples can be found in researches into the ecology of coronary heart disease, duodenal ulcer, schizophrenia, mental subnormality, suicide, accidents, and several other conditions.

To sum up, social scientists are studying a great many things of considerable interest to medicine and public health. They have “gained fruitful attention to the growing place of medicine and medical practice in the social system, and to different attitude and values which various segments of the population have towards health, illness and medical care. They have made noteworthy advances in mapping out the social organization of health personnel; the social structure and functioning of hospitals have been studied to advantage, as have the social roles played by patients and health personnel as they interact in different settings. They have paid particular attention to the situation of health personnel who are professionals, and to the social processes through which these persons acquire the outlook, standards and competence considered necessary for providing satisfactory professional services. They have also undertaken investigations which relate various social and psychological factors to different kinds of diseases in patients as well as to the course of certain diseases" (2).
SOCIAL AND BEHAVIOURAL SCIENCES

Medicine and social sciences are concerned in their own special way with human behaviour. The term 'social sciences' is applied to these disciplines which are committed to the scientific examination of human behaviour. These are economics, political science, sociology, social psychology and social anthropology. The term 'behavioural sciences' is applied to the last three, i.e., sociology, social psychology and social anthropology, because they deal directly with human behaviour. Each of these disciplines, while sharing the major goals of social sciences, i.e., the scientific examination of human behaviour deals with specific aspects of public health in the study of man.

(a) ECONOMICS

The field of economics has a very close relationship with sociology. It is the parent discipline from which sociology has emerged. Economics deals with human relationships in the specific context of production, distribution, consumption and ownership of scarce resources, goods and services. Sociology and economics overlap in many senses; both are concerned with interdependence in human relations.

(b) POLITICAL SCIENCE

Historically economics and political science tended to be a single discipline. As a separate discipline, political science is concerned with the study of the system of laws and institutions which constitute government of whole societies.

(c) SOCIOLOGY

Sociology deals with the study of human relationships and social behaviour for a better understanding of the pattern of human life. It is also concerned with the effects on the individual of the ways in which other individuals think and act.

(d) SOCIAL PSYCHOLOGY

This discipline springs from psychology. It is concerned with the psychology of individuals living in human society or groups. The emphasis is on understanding the basis of perception, thought, opinion, attitudes, general motivation and learning in individuals and how these vary in human societies and groups. In other words, it deals with the effect of social environment on persons, their attitudes and motivations.

(e) ANTHROPOLOGY

The word anthropology is derived from the root words anthropos meaning man and logos meaning science. It is the study of the physical, social and cultural history of man. The study of human evolution, racial differences, inheritance of bodily traits, growth and decay of the human organism is called physical anthropology. The study of the development and various types of social life is called social anthropology. The study of the total way of life of contemporary primitive man, his ways of thinking, feeling and action is called cultural anthropology (4). Of all the sciences, which study various aspects of man, anthropology is one which comes nearest to being a total study of man. Medical anthropology, deals with the cultural component in the ecology of health and disease.

SOCIOLOGY

Sociology is derived from the Latin socius, meaning society and the Greek logos, meaning science. The word society is derived from the root words social, meaning individual and socius, meaning group. Society is a group of individuals who have organized themselves and follow a given way of life, and sociology is the study of individuals as well as groups in a society. Sociology can be viewed from two angles: (a) First, it can be seen as the study of relationships between human beings, and how these relationships change or vary in different parts of the world and at different times. The unit of study can be a small group (e.g., family) consisting of parents and children, or the study can extend beyond the family or small groups into the complex society where a greater number of people interact and interdepend in terms of economics, political power, general organization and ways of living. (b) The other part of sociology is concerned with the study of human behaviour. Human behaviour is determined not merely by biological and physical environmental factors but also by social factors. Every form of human behaviour has a social component. Sociologists are interested in the study of the social determinants of human behaviour. In the final analysis it may be stated that the aim of sociology is to search for the pattern of relationships between people in order to pave the way for the betterment of individuals in relation to society (5).

SPECIALIZATION WITHIN SOCIOLOGY

Sociology has grown rapidly since World War II resulting in an increase in specialization within the general field of sociology. Some of the major fields of specialization are: medical sociology, urban sociology, rural sociology, industrial sociology, sociology of religion, sociology of education, criminology, hospital sociology, and demography.

MEDICAL SOCIOLOGY

Medical sociology is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. As a specialized field, it was first proposed by Charles McIntire in 1894 (6). It is defined as "professional endeavour devoted to social epidemiology, the study of cultural factors and social relations in connection with illness, and the social principles in medical organization and treatment" (6).

Broadly speaking medical sociology includes studies of the medical profession, of the relationship of medicine to public, and of the social factors in the aetiology, prevalence, incidence and interpretation of disease.

CONCEPTS IN SOCIOLOGY

Such terms as society, social structure, social institutions, role, socialization, social control mechanisms, customs, culture, acculturation, social problems, social pathology and social survey are frequently used by all sociologists and form part of the necessary equipment by means of which they organize their thinking, do research and communicate the results of research (7). Some of these concepts have also crept into medical terminology and are being increasingly used in epidemiological studies. A brief account of these concepts is given below.

SOCIETY

Human beings everywhere are members of a group or groups. A man who can live without society, said Aristotle, is either a beast or God. A group of people may or may not form a society. For example, a group of people coming together...
temporarily for a while to witness a hockey match do not constitute society; they are merely a crowd. But if the same group of people settle down and organize themselves, then they form a society. Thus, society may be defined in simple terms as an organization of member agents. The outstanding feature of a society is a system—a system of social relationships between individuals. The importance of society lies in the fact that it controls and regulates the behaviour of the individual both by law and custom. It can exert pressure on the individual to conform to its norms. In short, society is a vast network of relationships and compulsions that propel, direct, and constrain an individual's efforts. The structure of society is dynamic; it changes over time and place. Public health is an integral part of the social system. It is influenced by society, and society by public health. In many places it is the social organization that has made it possible to translate into practice the scientific concepts and achievements. As a result, the mortality rates have been brought to low levels and the life expectancy at birth has soared to very high levels.

COMMUNITY

Various definitions of community are given in dictionaries and other publications. Some imply homogeneity, e.g., "the people living in a particular place or region and usually linked by common interests" (6); or "a group of individuals and families living together in a defined geographic area, usually comprising a village, town, or city" (8).

The definition accepted by WHO Expert Committee is "A community is a social group determined by geographical boundaries and/or common values and interests. Its members have a common function within a particular social structure and exhibits and creates certain norms, values, and social institutions. The individual belongs to a broader society through his family and community (8)."

SOCIAL STRUCTURE

Social structure refers to the pattern of inter-relations between persons. Every society has a social structure—a complex of major institutions, groups, power structure and status hierarchy. The study of social structure is comparable to the study of anatomy and that of social organization to that of physiology.

SOCIAL INSTITUTIONS

A social institution is an organized complex pattern of behaviour in which a number of persons participate in order to further group interest. The family, the school, the church, the club, the hospital, political parties, professional associations and the panchayats are all social institutions. Within each institution, the rights and duties of the members are defined.

ROLE

In a society, individuals are allocated roles as people in a drama. Sociologists have classified roles into ascribed and achieved, according to whether a particular role is "given" by virtue of sex, age, and birth status or "acquired" by virtue of education or otherwise. In a single day, a man may play a role of husband, father, employee, friend, son, brother, committee chairman, guest, neighbour. The playing of these roles enables him to cooperate with others in many situations according to well-defined rules (9). When a person falls ill, he assumes what is known as a "sick role". In this role he is expected to decrease or relinquish his normal duties, seek medical aid, and carry out the orders given by the physician.

SOCIALISM

Socialism, to put it briefly, is the general term for any economic doctrine that favours the use of property and resources of the country for the public welfare. It is a system of production and distribution based on social ownership for raising the living standard of the working class, as opposed to capitalism which is based on private ownership of the means of production and aims at maximum private profit at the expense of the working masses. While the motto of capitalism is "all for each" and "each for all", that of socialism is "all for all" and "each for each". These are two extremes. Ever since Louis Blanc set forth the socialist principle "from each according to his abilities, to each according to his needs", socialism has undergone many changes and taken varied shades.

SOCIALIZATION

Every society has its beliefs, customs, traditions and prejudices. A man acquires these in his everyday social interaction with the people of the society. This is called "socialization" or the process by which an individual gradually acquires culture and becomes a member of a social group. Children going to school is an instance of socialization. The internship training programme of doctors is another instance; it gives them an opportunity to learn how to become acceptable to the public at large as doctors.

SOCIAL CONTROL MECHANISMS

In every society there are rules, formal and informal, for the maintenance of relationships of authority and subordination. The laws and enactments of Parliament are social control mechanisms. In the field of health, these are various Acts, some central and others state or local which help to maintain the standards of health. Even in small organizations, there are sets of formal rules and regulations which control the behaviour of individuals to perform different roles. Besides formal rules, sometimes, informal social pressures are brought to bear upon individuals to help construct "norms" of behaviour. The infarcted social pressure may be exerted by powerful groups, individuals or friends. These mechanisms work largely through reward and punishment. For example, in India, the government is offering a small financial reward to those who undergo sterilization operation. It is a sort of informal social pressure to further the programme of family planning in India. The social control mechanisms vary from group to group. A study of these mechanisms may be helpful to the community health worker in carrying out the health programmes.

CUSTOMS

The mere existence of a society, the mere plurality of individuals gives rise to customs from which no single member of the community can escape. The "highly developed" societies of the modern world are just as replete with social customs as the "primitive societies" of the past. These customs are quite numerous and quite as powerful. Customs are technically divided into "follows" and "mores". The follows are the right ways of doing things in what is regarded as the less vital aspects of human conduct. The more stringent customs are called "mores". The public takes an active part in their enforcement. Laws are generally customs-inspired. The starting point of all customs is
DYNAMICS OF SOCIAL CHANGE

The interaction between social factors and health issues is complex and sometimes unpredictable. For example, in Western Europe during the nineteenth century, increase in income and wealth, resulting from the Industrial Revolution, was accompanied by decrease in both birth and death rates. Many authors have in fact argued that increased income was the main cause of these changes (2). The situation in the developing world has varied and differs from the so-called "demographic transition" in Europe. In many parts of Asia, and to a certain extent in Latin America, death rates, particularly among infants, have declined steadily in the past decade and birth rates have declined rather dramatically. Yet the increase in income has been very modest. In Africa, on the whole, death rates, particularly of infants, remain high, birth rates are not declining, the benefits of increased income are not yet apparent, and concern over population growth is just emerging. The relationship between wealth, birth, and death rates observed in the development of West European countries, is thus obviously not universal (2).

A typical feature of traditional societies is a sense of continuity and immutability in patterns of social life. Transitional societies may be better able to cope with change, and modern societies are perhaps best adapted to assimilate rapid changes. A major difference between traditional and modern societies is that, in the former, young people can be fairly sure that their lives will be substantially similar to their parent's, while, in the latter, young people can be fairly sure that their lives will be substantially different from their parent's, and that their children's lives will be different from their own. In transitional societies, young people may simultaneously be involved in two cultures: the traditional one in which their parents grew up and which they still value, and the modern one which may be portrayed in the mass media. A similar clash of cultures may occur in the lives of young people whose families have migrated to another country or from a rural to an urban area (2).

SOCIAL STRESS

A major source of stress, particularly in transitional societies, is the conflict generated by new opportunities and frustrations arising from societal changes. These stress-inducing conditions include the wane of migration from rural to urban areas and the consequent diminution in the traditional family support system; a greater exposure through mass media to ideas that had been previously culturally alien; tourism; changes in the technological needs of society requiring skills that are different from those of the previous generation and for which the training or education available may be inadequate and the encouragement by commercial interests of economic aspirations that are often unrealistic (2). The pressure is more felt where young people have little control over their own destinies, where rapid population expansion means greater competition in the younger age groups, and where resources are inadequate to meet their needs.

It is well understood that the causation of physical and psychological disorders is multifactorial. The experience of stress, particularly in the absence of a social support system or when there is a discrepancy between the actual and perceived demands of a stressful situation, may contribute to further disorders (2). Psychological stress and inadequate coping ability has been implicated as a contributory factor in virtually all diseases (2). In particular, there are direct links between stress and hypertension and coronary heart disease.
SOCIAL PROBLEMS

In a community, there are both individual and social problems. Individual problems become social problems when they affect a large number of people amounting to a threat to the welfare or safety of the whole group. But all individual problems are not social problems. Poverty, crime and disease are the common social problems. Many public health problems are social problems and vice versa. Alcoholism, venereal diseases, mental illness and narcotic addiction are both, public health and social problems. Such social problems as housing, divorce, population growth, increased number of old people have public health implications calling for a combined sociological and public health action.

SOCIAL PATHOLOGY

The term “social pathology” is given a restricted interpretation linking it to poverty, crime, delinquency and vagrancy. In the modern context, the term is also used to describe the relation between disease and social conditions. The social pathology of accidents, diabetes, cardiovascular disease, cancer, chronic bronchitis have all been subject of recent investigations in medical literature. Social pathology is uncovered by "social surveys".

SOCIAL SURVEYS

Social surveys disclose social pathology. Social surveys have played an important part, in the development of public health. It was such a survey by Chadwick that led to the foundation of the General Board of Health in 1848 in Great Britain. There is a strong kinship between epidemiological survey and social survey. When the objective of the research is to study the role of social factors in the aetiology of disease, the two merge into what is known as “social epidemiology”. Large scale social epidemiological studies have investigated the relationship of social factors to heart disease, cancer and arthritis (11).

CASE STUDY

Case study is a method of exploring and analyzing the life of a social unit — be that unit a person, a family, an institution, culture group, or even an entire community. Its aim is to determine the factors that account for the complex behaviour patterns of the unit and the relationships of the unit to its surrounding milieu. The case study differs from the survey in the respect that it attempts to collect a large amount of information from a small number of units whereas a survey collects a relatively small amount of information from a large number of units. Thus the case study can yield valuable data about the unit studied than is possible from survey data. A combination of survey and case study could, for example, provide more information about a population of interest than either method could do alone. A case study also has its limitations, i.e., a single instance may or may not be representative of a larger population.

FIELD STUDY

Whereas surveys are concerned with the breadth of knowledge (systematic collection of data from population or samples of population through personal interviews or other data-gathering devices), field studies are concerned with depth of knowledge; they involve observation of people in situ.

COMMUNICATION

The term "communication" refers to a social process — the flow of information, the circulation of knowledge and ideas, and the propagation of thoughts. The role of communication in community health is to help motivate people to accept ideas; the ultimate aim of communication is to bring about changes in behaviour. The mass media (e.g., speeches, drama, radio, tele-vision, posters) are extensively used as vehicles of dissemination of Information.

SOCIAL DEFENCE

A new concept has come into vogue in recent times — the concept of social defence. It covers the entire gamut of preventive, therapeutic and rehabilitative services for the protection of society from antisocial, criminal or deviant conduct of man. Included in this are measures relating to the prevention and control of juvenile delinquency, eradication of beggary, social and moral hygiene programmes, welfare of prisoners, prison reforms, elimination of prostitution, control of alcoholism, drug addiction, gambling and suicides (12). Many States in India have enacted the Children Act for the prevention and control of juvenile delinquency. Under the Suppression of Immoral Traffic in Women and Girls Act, services are being provided for the elimination of prostitution in society. Social defence is a system developed to defend society against criminality not merely by treating and defending the offended, but also by creating such conditions in the community which are conductive for a healthy and wholesome growth of human life. The Government of India renamed the Central Bureau of Correctional Services as National Institute of Social Defence in 1975. This Institute is under the Department of Social Welfare.

PSYCHOLOGY

Psychology is defined as "the study of human behaviour — of how people behave and why they behave in just the way they do”. It is concerned with the individual, his personality and behaviour. A knowledge of psychology is essential to know others better; to differentiate between the normal and abnormal, to understand attitudes, beliefs, learning and memory processes; and to help promote mental health in individuals and families.

Scope of psychology

Psychology is vast in its scope, as indicated by the numerous branches of psychology, e.g., normal psychology, abnormal psychology, educational psychology, social psychology, child psychology, applied psychology, psychoanalysis, etc. Medical psychology deals with patients suffering from disorders of the mind. Persons trained in medicine and psychology are called psychiatrists. Thus psychology includes every aspect of human life and every type of human relation.

DYNAMICS OF BEHAVIOUR

The theme common to community medicine and psychology is human behaviour i.e., manner of acting or of conducting one self. The main concern of psychology is to study human behaviour. Human behaviour is the result of physical and mental factors (body and mind) interacting in complicated ways. Behaviour is "the total reactions of an individual" accessible to external observation. Thought and understanding are implicit behaviour which are observable not directly, but solely by inference from other observable behaviours.

The broad categories of factors that may influence individual and community health behaviour include:

PSYCHOLOGY
knowledge, beliefs, values, attitudes, skills, finance, materials, time, and the influence of family members, friends, or opinion leaders, and even health workers themselves. Serious consideration must also be given to the community or social context in which a given type of behaviour occurs. Persuasive issues such as norms, male/female roles, ethnic discrimination, poverty, unemployment, and educational opportunities may limit the ability of some sections of the community to behave in a healthy manner (13).

Cultural and social factors provide a setting for individuals. However, behavioural decisions may also be made that are other than those predicted on the basis of these factors. Psychological factors relating to public health programmes may be considered under the heading of health, illness and treatment behaviours.

Health behaviour
Health behaviour refers to those activities people undertake to avoid disease and to detect asymptomatic infections through appropriate screening tests. For instance, sexually transmitted diseases can be prevented by avoiding sexual exposure with infectious sexual partners. Other health behaviours that might reduce the risks of infection include the use of condoms, of bactericidal products immediately before and after sexual exposure, and the appropriate use of antimicrobial agents with proper supervision (13). In addition the risks of transmission can be reduced by assisting in the detection of infection in sexual partners before they have further unprotected sexual exposure with other susceptible partners. People with good health habits (e.g., daily brushing of teeth, non-smoking) are less likely to develop venereal infection than those with poor health habits (13).

Illness behaviour
Illness behaviour refers to how people react to symptoms. Generally, people who detect symptoms will wait to see if the symptoms persist or worsen. If the symptoms continue, the affected person may seek advice from a doctor or a non-medical health professional.

Treatment behaviour
Treatment behaviour refers to those activities used to cure diseases and restore health. It is important for patients to take medication as directed, return for tests for cure, and cooperate in efforts to identify untreated cases. Research has not shown that any particular group or personality type is more compliant than any other.

All forms of behaviour are responses to stimuli. For example, a child may run towards a dog, based on the stimulus of the dog moving away. The response is to run towards the dog. To understand behaviour, we must find out the cause for stimulus. The goal of psychology is to find relations that exist between stimuli and responses.

RESPONSES
The various responses may be classified as follows:

i) Physical responses: habits, skills
ii) Organic responses: emotions, feelings, tension
iii) Intellectual responses: perceptions, thinking, reasoning

CAUSES
All behaviour is caused, and the causes are very complex. They include:

i) Environmental stimuli

Environmental stimuli (e.g., sight, smell, touch, etc.) stimulate the cerebral cortex through the impulses. The information received is assembled and evaluated. By another set of impulses, the cerebral cortex "orders" the behaviour of the individual. This is known as conscious behaviour. It is the behaviour determined by the standards or expectations of the society, e.g., professional behaviour of doctors with patients. This accounts for the variation in a person's behaviour in different situations.

ii) Emotions and feelings

Behaviour is also dependent on our feelings and emotions. These stimuli arise from within the body. When we say a person is blind with rage or paniklyed with fear, we mean that he is a victim or captive to his own emotions. Emotions thus affect our behaviour. The seat of primary emotions (e.g., anger, joy, hunger) is the thalamus in the brain. It is under the control of cerebral cortex. When the influence of cerebral cortex is removed, as for example, when an injury to cerebral cortex occurs, the person's behaviour may be affected.

iii) Needs

An individual's behaviour is also influenced by his needs. The terms—needs, wants, desires and urges—are used synonymously.

iv) Motivation

Motivation is an inner force which drives an individual to a certain action. It is the decision-making process. Without motivation, behavioural changes cannot take place.

v) Intellectual perception

A person's intellectual perception, thinking and reasoning can influence his behaviour in a given situation. That is why each individual behaves in ways which make sense to him.

Making adjustments

Behaviour is also described as an adjustment to meet the needs of a given situation. For example, when a person does not succeed in something there are several ways he or she can react:

- losing temper and complaining to everyone
- getting oneself or simply avoiding facing others
- making excuses for the failure
- accepting failure with good grace and making amends by changing his behaviour or otherwise.

This adjustment is both active and passive. That is why some people blow hot and cold to suit their physical and social environment.

Unconscious behaviour

There is also behaviour of which the individual is not conscious. For example, if ten people witness an accident, we get ten conflicting reports of the accident. This is because of certain forces (e.g., perceptions, prejudices, and notions) which colour the incident, over which the individual has no
EMOTIONS

An emotion is a strong feeling of the whole organism. Emotions motivate human behaviour. An emotional experience is characterized by both external and internal changes in the human being. The "external" changes are those which are apparent and easily seen by others such as changes in facial expression, changes in posture. By studying the facial expression we can find out if a person is angry, happy, depressed or elevated. The "internal" changes brought about by emotions are psychological such as rapid pulse, rise in blood pressure, increase in tension and pain. Usually these changes are temporary, and subside when the individual returns to the "normal". Some of the major emotions are:

Fear
Jealousy
Sympathy

Anger
Moodiness
Pity

Love
Joy
Lust

Hate
Sorrow
Grief

Scientists have proved that emotions can be a major barrier to communication. Man is indeed a slave to his emotions. The doctor should be able to understand the emotions of the patient. Once the emotional barriers are broken down, a mutual trust between the patient and the doctor develops, and the patient will begin to talk more freely about himself. This is the basis of doctor-patient relationship. The desirable qualities in a doctor are cheerfulness and an even temperament. Moodiness, emotional instability and getting easily upset are undesirable qualities.

Specific some emotions

(1) FEAR: Fear is the most common emotion of man. It may be due to fear of depression; flight or fight. Some of the common fears of man are — fear of the dark, fear of dogs, fear of snakes, fear of ghosts, fear of sickness, fear of death, etc. When the fear becomes exaggerated or unnecessary, it is called phobia. Such fears are common in patients with mental disorders. (2) ANGER: Anger or rage is another basic emotion of man. It is an aggressive and offensive type. Anger is a destructive force. If it is not controlled, it may impair a person even to commit murder (3) ANXIETY: Anxiety may manifest in such symptoms as rapid pulse and breathing, flushing, tremors, sweating, dry mouth, nausea, diarrhoea, raised blood pressure, etc. Patients admitted to hospitals are anxious. Anxiety leads to tension, and tension to pain. The doctor must understand the patient’s anxiety and give him reassurance. A kind word from the doctor or nurse works like a magic and gives the patient considerable relief from mental anxiety. (4) LOVE: Love is a feeling of attachment to some person. It is a basic emotion of man.

Role of emotions in health and disease

Emotional states determine human behaviour. Anger can cause a person to be rude and sarcastic. Disorders of emotion interfere with human efficiency — lack of concentration, lack of appetite, increased risk of accidents, lack of sleep, palpitation, etc. Emotional disorders in children may appear in the form of temper tantrums, abdominal pain, spasm, tics, and anti-social behaviour such as aggressiveness.

Psychosocial illness: There are a group of diseases known as "psychosocial diseases" (mild acting on body), e.g., essential hypertension, peptic ulcer, asthma, ulcerative colitis which are attributed to disturbed emotional states.

Control of emotions

A well-adjusted and mentally healthy person is one who is able to keep his emotions under control. One should not be carried away by one's emotions. Children should be shown love and appreciation so that they may grow into emotional maturity. For adults, a happy family life is basic for emotional adjustment. Patients who are anxious need reassurance and their fears must be allayed. The following tips may be useful in controlling one's emotions:

(a) Cultivate hobbies; good habits of reading and recreation;
(b) Adopt a philosophy of life to enable you to avoid mental conflicts;
(c) Try to understand your own limitations, and
dev elop a sense of humour. A study of psychology helps us to understand the basis of emotions and the need to keep emotions under control.

MOTIVATION

Motivation is a key word in psychology. It is an inner force which drives an individual to a certain action. It also determines human behaviour. Motivation may be positive (the carrot) or negative (the stick). Without motivation, behavioural changes cannot be expected to take place. Positive motivation is often more successful than negative motivation. Motivation is not manipulation. A motivated person acts willingly and knowingly. The terms motives, needs, wants, desires and urges are all used synonymously; these terms are interrelated and interdependent.

Kinds of needs and urges

It is difficult to define human needs. There are many kinds of needs and urges: (a) Biologic needs: These are survival needs. A hungry man needs food, a thirsty man needs water, a sick man needs medicine. There are other needs such as sleep, rest, recreation and fresh air. The doctor should be aware of these needs in the day-to-day care of the patients.
(b) Social needs: The need for companionship, the need for love and affection, the need for recognition, the need for education are all social needs. Some of these needs may be satisfied by the family, and some by the community. (c) Economic needs: Economic security, that is security from want, is one which everyone desires. (d) Ego-integrative needs: The desire for prestige, power and self-respect come in this category.

Motivation is contagious; it spreads from one motivated person to another. We make use of motives and incentives in community health work. Motivation of eligible couples for a small family norm is an important activity in the National Family Welfare Programme. Motivation is required to enlist people's participation in community health work.

INCENTIVES

Incentives are among the factors that stimulate motivation and encourage specific behaviours. Incentives can be either intrinsic or extrinsic, material or psychological, self determined or selected by others. An intrinsic incentive is the benefit that comes from solving one's own problems. Extrinsic incentives are rewards that do not relate directly to the goal towards which the desired behaviour is aimed, for example, financial compensation of individuals undergoing sterilization operation for family planning. Material
Incentives are tangible goods or services; psychological incentives include the satisfaction, self-esteem, or enhanced capabilities gained through a proposed course of action (1). LEGISLATION
Legislation can serve as an important tool to support promote and sustain activities at the community level. Laws should satisfy requirements and, at the same time be compatible with political, cultural, social, and economic situation of the country. This is essential because laws may antagonize the population and make the community uncooperative.

OBSERVATION
Treatment involves lot of correct observation of the patient’s condition. Observation involves two mental activities: perception and attention. Hypocrites, the Father of Medicine, laid the foundation of modern medicine by accurate observation of signs and symptoms. By observing an apple fall, Newton formulated the theory of gravity. Observation is important in science. It consists of the noting of the phenomena of life as they occur. It requires correct use of the senses of seeing, hearing, touch, smell, movements etc. A doctor should cultivate the habit of correct observation. Correct observation leads to correct thinking, reasoning and learning.

Observation promotes attention. To observe more carefully is called attention. A moving object attracts more attention than a static object, a large object attracts more attention than a small object, an uncommon object attracts more attention than, a common one, a bright color attracts more attention than a dull color. In attention, certain adjustments of the senses are involved such as turning the head, converging the eyes. In other words, attention means closer observation. Attention is not a fixed state or power of the mind. We constantly change our attention from one object to another according to the demands of the situation. Concentration, i.e., the focusing of consciousness on a particular object to the exclusion of all other objects has been defined as sustained attention.

Errors in perception
The word perception implies observation, recognition and discrimination. Perception takes place with the help of the senses. We use visual perception, auditory perception, olfactory perception, and muscular perception. The disorders of perception are: (1) Impairment: That is, the inability to recognize. This may be due to damage to the senses organs, e.g., anesthnesia. (2) Illusion: An illusion is a false perception. Mistrapping a rope for a snake, a tree for an animal are called illusions. Illusions occur in mental diseases. Illusions may be auditory or visual. (3) Hallucination: Hallucinations are an imaginary perception. It is a gross error of perception. Seeing objects that do not exist, hearing sounds that are false, seeing objects moving in a room are called hallucinations. Hallucinations occur in mental disorders.

ATTITUDES
Attitudes are acquired characteristics of an individual. They are more or less permanent ways of behaving. An attitude includes three components: (a) a cognitive or knowledge element (b) an affective or feeling element, and (c) a tendency to action. An attitude has been defined as a relatively enduring organization of beliefs about an object, subject or concept which pre-disposes one to respond in some preferential manner.

Attitudes are not learnt from textbooks, they are acquired by social interaction, e.g., attitude towards persons, things, issues and groups (e.g., government policies, programmes and administrative measures). It has been truly said that attitudes are taught, and not taught. Once formed, attitudes are difficult to change. The responsibility to develop healthy attitudes devolves upon parents, teachers, religious leaders and elders. Our success or failure in life depends upon our attitudes. Social psychology is largely a study of attitudes. In recent years, attitude surveys and attitude measurements have been widely used by psychologists and health professionals.

OPINIONS AND BELIEFS
Opinions are views held by people on a point of dispute. They are based on evidence available at the time. Opinions by definition are temporary, provisional. They can be looked on as beliefs for the time being. Beliefs, on the other hand, are permanent, stable, almost unchanging. These are usually derived from our parents, grand-parents, and other people we respect. We accept beliefs without trying to prove that they are true. Every community has its own beliefs. As beliefs are held strongly, they are often difficult to change. They can be harmful, helpful or neutral. It is thus easier to give up one’s opinions when faced with the facts; attitudes and beliefs do not succumb so easily.

INTERESTS
Numerous interests come into play in a communication situation. Most significant are our own interests of security, self-esteem. Then come the interests of the various groups we are associated with: primary and secondary, as well as the reference groups whose values and norms we aspire to. Our communities, casts, language groups, peer groups and other religious, social, political and professional groups so dear to us are vital to us and we respect the sociology and national interests that shape our selection of communications, and also the way we perceive them (2).

LEARNING
Learning is any relatively permanent change in behavior that occurs as a result of experience or practice. It means acquiring something new — new knowledge, new techniques, new skills, new fears and new experiences.

Learning is necessary for man’s survival and for human progress. It is self-loving. It is self-expression. It is not self-preservation. It is self-development. It is not self-satisfaction. It is the expression of the sociological and national interests that shape our selection of communications, and also the way we perceive them.

CONDITIONS AFFECTING LEARNING

(1) Intelligence: Learning depends upon the intelligence or mental faculty of an individual. It involves the activity of sensory adjustment and motor mechanisms of the body. The mental faculty is related to heredity, nutrition and IQ. Children with low IQ are poor learners; they may not learn at all.

(2) Age: The curve of learning reaches its peak between 22 and 25 years of age. After the age of 30, there is a sharp decline. It has been appropriately said: You cannot teach
"an old dog a new trick". (3) Learning situation: Physical facilities for learning, viz., institutes, teachers, textbooks, audio-visual aids promote learning. (4) Motivation: In order to learn effectively, there must be adequate motivation. The powerful motives are encouragement, praise, reward and success. These stimulate learning. (5) Physical health: A Physically handicapped person, e.g. deaf, dumb, chronically sick cannot learn. (6) Mental health: Worries, anxieties, and fears interfere with learning.

Types of learning
There are 3 types of learning:

(1) Cognitive learning (knowledge)
(2) Affective learning (attitudes)
(3) Psychomotor learning (skills)

Psychologists have experimented a good deal with animals and man to find out how learning takes place. They have proposed a number of theories: (1) Learning by conditioned reflex: It is well known that when dogs see food, they begin to salivate; this is an inborn reflex. Pavlov, the Russian physiologist discovered that if a bell was rung when the dogs were fed, eventually, salivation could be induced by the ringing of the bell alone. This is called conditioned reflex. The psychologists proposed that learning takes place partly by the mechanism.

(2) Trial and error: The lower animals such as apes and cats learn by trial and error method. We also learn a good deal by this method. A child tries and tries again using a number of approaches until accidentally the ideal approach, becomes obvious. This method of learning is very slow, laborious and primitive. (3) Learning by observation and imitation: We learn a good deal by observation and imitation. A child copies or imitates gestures, facial expressions and movements such as walking. He learns language by observation and imitation. Observation is an important element in medical examination. Observation promotes attention, discrimination and recognition. It may be by observation. Hippocrates, Father of Medicine, separated medicine from magic. Part of the doctor's and nurse's education has always been to observe the patient's condition, and to make deductions based on these observations.

(4) Learning by doing: In this type of learning there is coordination of muscular responses with sensory impulses. Nursing skills (e.g., bed making, applying bandages, giving bath) are learnt by doing. Learning to type-write or learning a new game or a musical instrument are all examples of learning by doing. (5) Learning by remembering: We also learn by memorizing - remembering dates, events, memorising a poem, remembering faces, etc. (6) Learning by insight: When we are faced with a problem, we solve it by insight or mental exploration. When the doctor makes a diagnosis, some amount of insight is involved. It appears that human beings learn by a combination of methods. (7) Demonstration: Here a procedure is carried out step by step, slowly and accurately before an audience, the demonstrator ascertaining that the audience understands how to perform it. The demonstration involves the audience in discussion, when possible.

(8) Field experience: It involves a series of activities for diagnosing problems, planning procedures to solve them and implementing and evaluating these programmes. It provides opportunities to acquire with number of skills. (9) Problem solving: It is closely related to field experience in that the problems are identified and plans to solve them are made, but if the time is short, fhe plans may be executed by another group of trainees or by the service staff.

Learning is measured by student's performance. There are many ways of measuring student's learning viz., multiple choice questions, essay questions, project work, practical examination, oral examination, etc. Usually a combination of different methods is used.

HABITS
Habit is an accustomed way of doing things, example in the field of health is washing one's hands before handling food. It is usual way of action or an act performed without thinking. Habits are said to have 3 characteristics: (a) they are acquired through repetition (b) they are automatic, and (c) they can be performed only under similar circumstances. Habits accumulated through generations emerge as customs and in turn create habits. Habits once formed persist and influence human behaviour.

Habit formation
Habits are formed. They are of many kinds, e.g., habits relating to food, sleep, work, smoking, intake of drugs and alcohol, etc. There are both good and bad habits. Good habits promote health; bad habits (e.g., drug dependence) may ruin health. Therefore, cultivation of good habits is desirable. The principles involved in habit formation are:

(1) Habit formation should begin early in childhood, when the child has not yet formed any habits, and is receptive to all influences;

(2) Habits are formed by frequent repetition;

(3) It takes time to form habits; they cannot be formed overnight;

(4) There should be a strong emotional stimulus to form habits (e.g., taking a vow, reward, recognition, etc.);

(5) Good habits kill bad habits. The best way to break bad habits is to cultivate good habits.

Habits build up human personality. Man should not become a slave to his habits, he should remain a master. It is the job of the psychologist to find out how good habits can be developed and bad ones eliminated.

FRUSTRATIONS AND CONFLICTS

Frustrations
All people have needs - biological, social, economic, which they try to satisfy. When they are unable to meet their needs and desires, they feel frustrated.

The sources of frustration may be external - e.g., unemployment, failures and defeats, or, internal - e.g., lack of health, lack of intellectual ability, etc.

Sometimes, frustration may cause the individual to higher and bigger effort to overcome failures. The individual may bypass the frustration conditions by changing his goals in life. Frustration, if it is allowed to continue, may damage one's personality. It may generate feelings of anger, depression, hostility, withdrawal or even attempts at suicide. That is why some people take to drugs and alcohol to escape frustration.

Conflicts
A conflict is like a tug of war between two or more courses of action or between opposing ideas. The person is required to act one way or the other, often generating painful emotions as for example in choosing a life partner or
a job. He has to weigh the pros and cons of the situation to be able to make a correct decision. It is essential for a person's mental health that conflicts should be resolved as quickly as possible, within a reasonable period of time, before emotional disturbances occur.

DEFENCE MECHANISMS

When an individual is faced with problems, difficulties or failures, he employs certain ways or devices to achieve health, happiness or success. These are called defence mechanisms. Psychologists have identified a number of such defence mechanisms, which include the following:

1. Rationalization

Instead of accepting failure and correcting himself, the individual tries to make excuses and justifies his behaviour. It is like the proverbial fox declaring that the grapes were sour, when it could not reach them. This is called rationalization. It is a face-saving device.

2. Projection

Sometimes the individual blames others for his mistakes or failures. It is just like the student saying that he could not score good marks in the examination because, his teacher did not like him.

3. Compensation

Many people make use of compensation to enhance their self-esteem and prestige. The familiar example is that the student who is not good in his studies may distinguish himself in sports or dramas, music or other activities.

4. Escape mechanism

Some individuals adopt what is known as an "escape mechanism" to overcome failure or defeat. Some students pretend illness and do not appear for examinations. This is an escape phenomenon. Then there are others who take to alcohol or drugs trying to solve their problems. This is also an escape phenomenon.

5. Displacement

As office clerk badly snubbed by his superior takes it out on his wife and children on reaching home. This is like a rebound phenomenon. It is trying to escape from one situation and fixing blame on another situation.

6. Regression

Some people resort to childhood practices (e.g., weeping when something goes wrong) as a mode of adjustment.

The above list of "defence mechanisms" serves to illustrate the various modes of adjustments the individual adopts to escape from realities. He is either too keen to hide his faults, or run away from his troubles and problems. A mentally healthy person will not use defence mechanisms for achieving success or happiness.

PERSONALITY

The term "personality" is a key word in psychology. It implies certain physical and mental traits which are characteristic of a given individual; these traits determine to some extent, the individual's behaviour or adjustments to his surroundings. The terms personality and human behaviour are inter-related. Psychology, in its broader concept, implies study of human personality. It is important to bear in mind that the personality of the doctor affects very much the well-being of the patient.

Components of personality

There are at least 4 components of human personality:

1. PHYSICAL: These are the physical traits or features of an individual namely height, weight, colour, facial expression, physical health, etc. To the layman, a good personality means an impressive, symmetrical and healthy body.

2. EMOTIONAL: A person's emotions also go into the make-up of his personality. Emotions are the feelings we have -- fear, anger, love, jealousy, guilt, worries. These feelings affect an individual's personality. (3) INTELLIGENCE: Personality also implies intellectual ability. An intelligent person will have a forceful personality. A person with sub-normal intelligence is described as a "dull" person. (4) BEHAVIOUR: Behaviour is a reflection of one's personality. It is partly dependent upon our feelings and partly on the expectations of the society. Behaviour is described in such terms as gentle, kind, affectionate, balanced, submissive and aggressive. When we assess human personality, all these components must be taken into consideration.

Personality traits

A trait is described as tendency to behave in a consistent manner in various situations. Human personality is a bundle of traits. The basic personality traits are established by the age of 6 years. Some traits, we cultivate (e.g., good manners); some, we may conceive (e.g., kindliness); and some, we modify depending upon the society in which we are placed (e.g., sense of humour). The following are some of the personality traits:

- Cheerfulness
- Loyalty
- Good manners
- Reliability
- Sportsmanship
- Sense of humour
- Honesty
- Tactfulness
- Kindness
- Willing to help others.

The personality traits we look for in a doctor are kindliness, honesty, patience, tolerance, perseverance, consciousness, thoroughness and initiative. It is possible to cultivate these traits.

The Swiss Psychiatrist, Carl Jung (1875-1961) divided personalities into 2 types -- extravert and introvert. The extravert is a person who is thought to be smiling, practical, active, showing-off and easily mixes with people. An introvert is a person who is reserved, shy and generally keeps to himself. Most people exhibit characteristics of both.

Development of personality

Human life consists of definite stages of growth, and each stage is marked by distinctive psychology. (1) INFANCY: The first one year of life is called infancy. The infant is hardly a social creature. There is rapid physical and mental growth. The infant is totally dependent on the mother. By the end of first year, the infant is able to stand up for a short while and tries to walk with a little support. He enjoys simple tricks and games. (2) PRE-SCHOOL CHILD: This stage is marked by considerable growth of brain. The child feeds himself, speaks, loves his home, fears dark, loves stories and wants to assume responsibility. He begins to mix with other small children. (3) SCHOOL-AGE: The school-age period ranges from 6 to 15 years. The school-going child is active all the time. By the age of 8, the mental powers are fully developed. The brain of the child at the age of 8 years is almost of the same size as an adult. The child begins to
reason. There is a gradual detachment from the ‘family, and greater attachment to his playmates and friends. He begins to form groups. The period of childhood terminates with the onset of puberty, which is about 11 years in the case of girls and 13 in the case of boys. (4) ADOLESCENCE: Adolescence or “teenage” is a turbulent period in one’s life. This is a period of rosy dreams, adventure, love and romance. The teenager strives for independence. He dislikes parents’ authority, becomes fully aware of social values and norms. There is rapid physical growth. (5) ADULTS: The person is mature and more balanced. The physical and mental characteristics are fully developed. It is difficult to draw a line when adolescence ceases, and adulthood begins. (6) OLD AGE: It is difficult to say when old age begins. It is a gradual process marked by decline in physical powers and acuity of sense organs. Old age is marked by certain psychological changes such as impaired memory, rigidity of outlook, irritability, bitterness, inner withdrawal and social maladjustment.

Character and will

The concept of personality also involves assumptions about character and will of the person. Will indicates determination and character implies moral worth. Personality and character are not identical, both are different. Man’s character may be good at one time and bad at another time, though his personality remains the same. There is no adequate definition of character.

THINKING

Man is called a thinking animal. Thinking includes perception, memory, imagination and reasoning. It is an active mental process. Imaginative thinking is a mental process, it involves thinking to the original sensory stimuli. Day-dreaming and thinking about our future plans are examples of imaginative thinking. The highest form of thinking is said to be creative thinking, e.g., an artist painting a picture. Creative thinking is said to be responsible for new inventions, new views of life and new discoveries. The anatomical basis of thinking is cerebral cortex. In fact, the purpose of education is to teach people to think, and not merely to memorize facts and figures.

Problem solving

An aspect of thinking is problem solving. It is regarded as the highest stage in human learning. Some problems in life are relatively simple; there are others which are more difficult and complex calling for thinking and reasoning. REASONING requires intelligence. There are several steps in the reasoning process – collection of information on the subject, the arrangement of data carefully, observation of the implications, drawing conclusions and testing the conclusions. An intelligent person reasons well. Reasoning is not always fool-proof. Failures may also occur.

INTELLIGENCE

Intelligence is an important aspect of personality. It has not been satisfactorily defined as yet. The widely accepted definition is that it is the ability to see meaningful relationships between things. It includes perceiving, knowing, reasoning and remembering. Psychologists believe that intelligence results from an interplay between hereditary and environmental factors. Some psychologists emphasize genetic factors as having major significance while others emphasize environmental factors.

There is considerable relationship between a person’s degree of intelligence and range of activities, the level of achievement and the depth of understanding possible to him. As psychologists observed the differences between animals and human beings, and the differences between organisms of the same species, they were impressed by the fact that there are variations in the case and adequacy with which adjustments to new situations occur. It was out of such observations that the concept of intelligence arose.

Mental age

The first tests of intelligence were devised by Binet and Simon (1896). They developed the concept of mental age. That is, a child who could do the five-year tests but who could not go on the six-year test, was credited with mental age of five years. The concept of mental age indicated the level of intelligence achieved, but it gave no indication of the brightness or dullness of the individual concerned. Tarman revised these tests, defining intelligence as the capacity to use abstract ideas for solving problems. Gesell indicated four sectors of intellectual development for consideration: (a) motor ability (b) adaptive behaviour (c) language development and (d) personal-social behaviour.

Intelligence Quotient

This is an improvement over the concept of mental age. It is obtained by dividing the mental age by chronological age, and multiplying by 100.

\[
IQ = \frac{\text{Mental age}}{\text{Chronological age}} \times 100
\]

When the mental age is the same as chronological age, the IQ is 100. The higher the IQ, the more brilliant the child. 80 per cent of people have an IQ of 90 or near 100. On the other hand, say for example, if a child is 10 years of age and his mental age level is that of 5 years, the IQ is 50.

<table>
<thead>
<tr>
<th>Levels of Intelligence</th>
<th>IQ Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idiot</td>
<td>0–24</td>
</tr>
<tr>
<td>Imbecile</td>
<td>25–49</td>
</tr>
<tr>
<td>Moron</td>
<td>50–69</td>
</tr>
<tr>
<td>Borderline</td>
<td>70–79</td>
</tr>
<tr>
<td>Low normal</td>
<td>80–89</td>
</tr>
<tr>
<td>Normal</td>
<td>90–109</td>
</tr>
<tr>
<td>Superior</td>
<td>110–119</td>
</tr>
<tr>
<td>Very superior</td>
<td>120–139</td>
</tr>
<tr>
<td>Near genius</td>
<td>140 and over</td>
</tr>
</tbody>
</table>

The current interpretation is that the IQ is the measurement of the quality and potential of intelligence. The higher the IQ the more “brilliant” the child is and is more capable of higher performance at school age.

ADULT INTELLIGENCE

The components of adult intelligence have been analyzed by many specialists. Thurstone (15), for instance, defines them as:

1. space: the ability to perceive objects
2. number: familiarity with elementary arithmetic
3. verbal comprehension: the ability to reason from verbal concepts
4. facility of expression: the ability to employ the appropriate words
5. memory: the ability to retain words and ideas
Intelligence tests can be classified under the categories of group tests and individual tests. These two kinds of tests have been constructed mostly to meet practical necessities. Naturally, if large numbers of subjects are to be tested, it would be convenient to test them in large group tests. However, in some situations, such as giving guidance, each individual could be tested separately and would need to be tested separately. To suit these different requirements, we now have both group tests and individual tests. In a group test, all the subjects must start at one time and finish at the same time just as in an examination. Here, the time factor is constant. One's intelligence is measured in terms of the amount of work successfully completed within the given time. Individual tests on the other hand need not necessarily depend on a constant time factor. Time tests can also be used for individuals. Strictly speaking, all tests of intelligence are measures of performance. However, the term performance is customarily applied to tests which call for a minimal understanding and use of language. These tests provide a measure of fundamental psychological process, such as reasoning and seeing relationship, without at the same time depending upon particular cultural or educational opportunities. They enable us to measure the intelligence of individuals — (1) who are too young to have learned a language, (2) who are illiterate through lack of educational opportunity or feeble-mindedness, and (3) who speak only a foreign tongue.

As the child grows older, his intelligence undergoes a gradual increase. There is an improvement in age in his versatility of adjustment — in the readiness with which he gathers information and acquires new skills which enable him to adjust to the changing circumstances of his environment. When a normally healthy school child, whose educational opportunities have been average, is tested year after year, his IQ remains fairly constant. Changes in educational opportunities lead to fluctuations in IQ. There are cases on record, too, where the IQ rose considerably after psychiatric therapy.

The chief values of discovering a child's IQ are that: (1) those of low IQ can be taken aside for special education in line with their capacity to acquire intelligent behaviour; (2) those of very high capacity can be selected for education in keeping with their capacity; (3) intelligence tests as an aid in the determination of the right time to enter school; (4) the use of intelligence test in maintaining the adjustment of a pupil to his work; (5) the selection of applicants for college and professional school; (6) the use of intelligence test in educational guidance; and (7) the use of intelligence test to the therapist (16).

Measurement of disability

There have been many attempts to measure or record in standardized form the aspects of behaviour, psychological functions and social performance. One of the most important is Wing's Comprehensive Handicap Schedule (CHS) which has been used in epidemiological studies to assess the total child population in terms of detailed scales of specific abilities and disabilities. Results from these surveys have raised important questions about ethnic differences in disability profiles, individual programme planning, defining new syndromes of disability and the possibilities of new parameters for classification. The CHS is essentially a research tool, but Wing has developed from it a small practical schedule for use in service contexts using what had emerged as the most important aspect of mobility, communication and social interaction. The resulting Disability Assessment Schedule (DAS) is being used in several communities as a source of high quality routine data for total population (17).

Group behaviour

Man is a social being. From birth till death, he is associated with people. He is born in a particular culture which is made up of customs, laws, ideals, ·et, literature, crafts, science, technology and institutions. All these act on the individual and influence his social behaviour. Group behaviour is also known as social behaviour.

Social interaction

(a) Inter-personal relationships: The individual learns many things from his parents, teachers and friends. This is known as person-to-person relationship.

(b) Inter-group relationships: The individual is a member of a group, and is influenced by a group. He has to follow the traditions of the group. For example, in many communities in India the person is not permitted to marry outside his caste. This is the result of person-to-group interaction.

The individual, through social interaction and social learning acquires patterns of behaviour prevalent in his society, and is accepted as a member of that community. This process of adaptation is known as socialization. Social interaction converts the biological organism into human, social and moral.

As a result of social interaction, the individual acquires attitudes towards persons, things, situations and issues. Social attitudes are shared by others in the community, e.g. attitude to prohibition, family planning, child marriage, etc. In any democratic society, people's attitudes are a measure of vital importance to the State.

Group morale

Every group has leaders. They are responsible for the solidarity of the group behaviour and the morale of the people in the group.

Groups work together. They have definite programmes and objectives. Often their members think, feel and act together. Many community problems can be solved by group efforts. We can approach the group through group discussions. The problem is one of how to make these group activities happy and satisfying experiences for those who participate in them.
SOCIETY

Sociology is the science of society. It deals with the study of relationship between human beings. It also deals directly with the study of human behaviour. Whereas the unit of study of psychology is the individual, the unit of study of sociology is the group. Sociology studies man in the context of society and as a part of it.

Med~cal sociolog~ is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. Illness is viewed not only as a medical problem but also as a psychological and social problem. The problems presented by patients are not always purely medical but also psycho-social. Diseases such as tuberculosis, leprosy, sexually transmitted diseases have a big social component in their aetiology. Medical sciences are increasingly turning their attention to the study of social, behavioural and cultural factors of illness. A social approach to disease treatment is also emphasized. The doctor needs to have a fuller appreciation of biological, behavioural and social sciences. A successful doctor must possess a knowledge of the community and the factors which affect the health of the community.

THE INDIVIDUAL

Rights of the Individual

During the 19th Century, the rights of man received some small recognition. In 1946 the subject of human rights again received attention. In 1948, the General Assembly of the United Nations adopted the Universal Declaration of Human Rights. The declaration consists of 30 Articles, and recognizes that all human beings are born free and equal in dignity and rights. The right to better living conditions, and the Right to Health and Medical Service are vital utilities. In 1959, the General Assembly of the United Nations also adopted. “The Declaration of the Rights of the Child”. The Universal Declaration of Human rights speaks of the right to health in the following terms:

- Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing, and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his control.
- Motherhood and childhood are entitled to special care and assistance. All children, whether born in or out of wedlock, shall enjoy the same social protection.

The Constitution of the World Health Organization expressed itself as follows:

- The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition.
- Most countries of the world have accepted the idea of the right to health.
- The Constitution of India guarantees 7 broad categories of fundamental rights:
  1. the right to equality
  2. the right to freedom of speech and expression
  3. the right against exploitation
  4. the right to freedom of practice and propagation of religion
  5. the right of minorities to conserve their culture
  6. the right to protection of life and personal liberty
  7. the right to constitutional remedies for the enforcement of fundamental rights.

Responsibility for health

Although health is now recognized as a fundamental right of every human being, it has to be earned by individual effort. It cannot be given by one person to another.

The responsibility for health rests not only on the individual but also on the community or State. There are certain responsibilities which the individual must accept or exercise in order to achieve optimum health. These are responsibilities regarding personal health, e.g., diet, care of teeth, skin, recreation, exercise, cultivation of healthful habits, immunization, reporting early when falling sick, optimum utilization of available health services, etc.

In all civilized societies, the Government or State assumes responsibility to safeguard or promote the health and welfare of its citizens. Russia was the first country to give its citizens a constitutional right to all health services. There is provision for health in the Constitution of India. The Directive principles of State policy of the Constitution of India states:

- The State shall, in particular, direct the policy towards securing —
  - That the health and strength of workers, men and women and the tender age of children are not abridged so that citizens are not forced by economic necessity to enter a vocation unsuited to their age or strength.
  - That children and youth are protected against exploitation and against moral and material abandonment.
  - The State shall, within the limits of its economic capacity and development, make effective provision for securing the right to work, to education and to public assistance in case of unemployment, old age, sickness and disablement, and in other cases of undeserved want.
  - The State shall, make provision for securing just and humane conditions of work and maternity relief.
  - The State shall regard the raising of the level of nutrition and standard of living of its people and the improvement of public health as among its primary duties.

SOCIAL ORGANIZATION

Society is a group of individuals drawn together by a common bond of nearness and who act together in general for the achievement of certain common goals. The individual needs the group – not necessarily a particular group or always the same group or the same group for all needs. Different groups are needed for different purposes; these groups comprise social organization.

The social groups to which people belong are the family, the kinship and caste, religion, village, town or city and the state. Besides these, there are certain functional groups such as the parish, the club and various associations. Cutting across these groups, there are groups based on social status.
1. THE FAMILY
The family is the basic unit in all societies. It is the most powerful example of social cohesion. A detailed discussion of the nature and functions of the family is given in the following pages.

2. RELIGION AND CASTE
The caste system in India is an example of a "closed class", i.e., there is no mobility or shifting from one class to another, and the members remain throughout their lifetime within which they are born. Each caste is governed by certain rules and sanctions relating to endogamy, food taboos, ritual purity, etc. Each caste group within a village is expected to give certain standardized services to the families of other castes. For example, a barber (nail) cuts hair, a potter supplies earthenware vessels. In the towns and cities and industrial areas, the caste system, although existing, is not rigid: there is considerable intermarriage and interpersonnel relationships not strictly based on caste hierarchy.

3. TEMPORARY SOCIAL GROUPS
(1) The Crowd: When a group of people come together temporarily, for a short period, motivated by a common interest or curiosity (e.g., to witness a football match), it is known as a crowd. The crowd lacks internal organization and leadership. When the interest is over, the crowd disperses. (2) The Mob: The mob is essentially a crowd, but has a leader who compels the members into action. There may be a symbol in the shape of a flag or slogan. The mob is more emotional than a crowd. Like the crowd, it is unstable and lacks internal organization. When the purpose of the mob is achieved, the group disperses. (3) The Herd: This is also a crowd with a leader. Here the members of the group have to follow the orders of the leader without question, e.g., the touristic group under a guide.

4. PERMANENT SPATIAL GROUPS
(1) The Band: It is the most elementary community of a few families living together. The band has organized itself and follows a pattern of life, e.g., gypsies in India. (2) The Village: The village is a small collection of people permanently settled down in a locality with their homes and cultivating the land. It is the practical unit of the Indian village economy, which has constituted a basic unit in India. According to the 2011 census, there were 670,867 villages in India. The average population of a village is estimated to be 256. This is the general picture, although there are variations. In Kerala for example, houses are not in clusters; it has been stated that the villages in India are like "little republics having nearly everything they want within themselves; and almost independent of foreign relations; they seem to live where nothing else exists". The survival of the villages and in fact Indian culture, during periods of foreign dependence, has been due to the continuity of village organization. Castes, religion, rituals, kinship, marriages and economy are some of the important aspects of the Indian villages. (3) The Towns and Cities: From a sociological point of view, a city or town may be defined as a relatively large, dense and permanent settlement of socially heterogeneous individuals. The community is subdivided into smaller groups or the basis of wealth and social class. Because of their size, primary contact among all its inhabitants is difficult. The 2011 census enumerated 7,925 towns and cities in India. When the population exceeds 100,000 it is called a city; on this basis, there were only 107 cities in India at the time of 1961 census. (4) The State: The state is an ecological social group based on territory. It is more stabilized and formalized. It is heterogeneous in nature. The Indian Union is a large State.

5. GOVERNMENT AND POLITICAL ORGANIZATION
Some form of government is detectable even among primitive societies. Government is an association of which law is the institutional activity. There is no society which lacks government. It is the supreme agent authorized to regulate the balanced social life in the interests of the public. To understand the organization of medical services in any country, it is essential to know its social and administrative organization.

The various types of government in different countries of the modern world are as follows: (1) Democracy: This is government of the people, by the people and for the people. The people have this form of government. (2) Autocracy: The ruler is absolute in power, as in Jordan and Ethiopia. (3) Monarchy: The head of the State is a monarch found in the UK and Nepal. (4) Socialistic: The production and wealth are owned and controlled by the State. Examples are China and Poland. (5) Oligarchy: The country is ruled by a family group, e.g., Thailand, Cambodia, Saudi Arabia.

In capitalist countries, medical service is given to the population by various agencies in various ways. State medicine, insurance medicine, charity medicine and private medicine exist side by side. Medicine has developed into a trade - a service that is purchased by the patient and sold by the physician under a competitive system. In socialist countries, medicine, like education, is not a trade; it is a public function of society. All health activities are directed and controlled by central bodies, medical service is free and therefore available to all. It is, in other words, socialized medicine.

THE FAMILY
The family is a primary unit in all societies. It is a group of biologically related individuals living together and eating from a common kitchen. The term family differs from household in that all the members of a household may not be blood relations, e.g., servants. As a biological unit, the family members share a pool of genes - a social unit, they share a common physical and social environment. As a cultural unit, the family reflects the culture of the wider society of which it forms a part and determines the behaviour and attitudes of its members. The family is also an epidemiological unit, and a unit for providing social services as well as comprehensive medical care. The family therefore has engaged the attention of sociologists, anthropologists, demographers, epidemiologists, medical scientists, and in fact all those who are concerned with family welfare.

The word, family, which is used in popular term, has made a good deal of confusion among the professionals. It is used in very many different senses. To avoid confusion, social scientists have used the term: (1) Family of origin or the family into which one is born, and (2) Family of procreation or the family which one sets up after marriage.

Family life cycle
Families are not constant; they are ever changing. A normal family-cycle is generally conceived as having six phases (table 1).
<table>

Source: (19)

Such a model, however, tends to apply only to areas of low mortality and requires amendment in high mortality situations to reflect the early death of children and even the death of the mother before any of the children are old enough to leave home. Moreover, “leaving home” is essentially an American and European phenomenon that has little relevance in many developing countries in Africa and Asia. A number of variations and exceptions, then, to the typic life cycle such as the early death of children or one spouse, divorce, childlessness, etc., need to be taken into account.

Family cycle and stress
Structure
Each family experiences its own dynamics of formation, growth, maturation, and dissolution. Crises confronted may be divided into those that are transitional in the family life cycle (e.g., birth of first child or loss of spouse) or nontransitional (e.g., acts of war, uprooting, mental disorders, etc.). Family sociologists have studied effects of sudden shifts in economic status, migration, mitting, disasters, physical change or incapacity of a family member, and impact of crises at various stages of the family life cycle. It has been suggested that stress and health hazards are likely to increase when environmental changes occur at critical developmental periods such as, adolescence, first pregnancy, menopause, and retirement. The ability to cope is given situation depends, in part, on perception of threat, motivation and readiness to respond creatively, available emotional and social supports, and cultural provisions. Compared with other social organizations, the average family has distinct disadvantages. Its age composition is heavily weighted by dependents and is of uncertain sex distribution. No other institution is so removed to crises and stress yet so potentially capable of resolving frustration and relaxing tension (19).

Childhood
As noted by number of observers, the literature on delinquency, psychiatric conditions, mental disorders, and other childhood disorders has produced considerable knowledge on insecurity, and incompetence, and on the damage done by marital discord, parental rejection, and institutional caring. Much less is known about conditions facilitating normal development or why some children with a variety of unfortunate disadvantages still manage to develop a healthy personality, emotional security and social competence. Concern with childhood mental disorders is especially appropriate in developing countries, where children under 15 years of age account for about 40 per cent of the population compared to about 25 per cent in developed countries. Poverty and low socio-economic status appear to be associated with a greater incidence of mental disorder (19).

Adolescence
While the age of puberty and physical maturation does not vary greatly throughout the world, adolescence as a stage of physiological growth is more closely associated with economic development, social and cultural values, and historical traditions. The age at which this development phase occurs may differ between countries within the same geographic region. Few countries really have adequate information on drug abuse, the sequelae of inappropriate sex behaviour, alcoholism, and related difficulties.

Parenthood
In modern society, preparation for parenthood is a complex and changing task. Parental skills do not necessarily come easily and naturally. In part, parents behave the way they do because of their own childhood experiences. Persons reared in unhappy, discordant, or disruptive homes are more likely to marry in their teens, to have out-of-wedlock children and to experience unhappy marriages and difficulties in child rearing (19). Such links between childhood experiences and subsequent parental behaviour are not inevitable. There appear to be considerable capacity for modification of parental behaviour, as shown most frequently in the differential treatment of the second child. The stereotype roles of parenthood are losing their validity amidst cultural changes. There appears to be greater social sensitivity too, for example, parent-child communication when one parent dies, the death of an infant is the family, early childhood intervention, single parent families headed by women, and the relationship of family circumstances to wider social environment.

Ageing
India’s population ages 60 and older is projected to increase dramatically from 8 per cent in 2010 to 19 per cent in 2050. By mid-century, this age group is expected to encompass 333 million people, a number greater than the total U.S. population in 2012. This profound shift in the share of older Indians—taking place in the context of changing family relationships and severely limited old-age income support—brings with it a variety of social, economic, and health care policy challenges. The ageing of India’s population will lead to increases in the prevalence of chronic conditions such as diabetes and hypertension. By one measure, nearly one-half (45 per cent) of India’s disease burden is projected to be borne by older adults in 2030, when the population age groups with high levels of chronic conditions will represent a much greater share of the total population (194). Similar increase in the population of older persons can be anticipated in other regions of the world.

Types of families
Family units throughout the world are not the same. Industrialization, urbanization, democratization and acculturation have affected the family structure and life. Social scientists have described three main types of families.

1. NUCLEAR FAMILY
The nuclear or elementary family is universal in all human societies. It consists of the married couple and their children while they are still regarded as dependents. They tend to occupy the same dwelling space. In the nuclear family, the
humand usually plays a dominant role in the household. The absence of grandparents, uncles, aunts and near relatives places a greater burden on the nuclear family in terms of responsibilities. The husband-wife relationship is likely to be more intimate in the nuclear family than in the joint family. The term "new families" has come recently into vogue; it is applied to those under 10 years of age and consist of parents and children. The concept is important in view of studies relating to family planning (20).

2. JOINT FAMILY

The joint or extended family is a kind of family group which is common in India, Africa, the Far East and the Middle East. It is more common in agricultural areas than in urban areas. The orthodox Hindu family in India is a joint family. As a price for education, urbanization and industrialization, we are losing the joint family system. The main characteristics of a typical joint family are (21):

(1) It consists of a number of married couples and their children who live together in the same household. All the men are related by blood and the women of the household are their wives, unmarried girls and widows of the family kinship. (2) All the property is held in common. There is a common family purse to which all the family income goes and from which all the expenditures are met. (3) All the authority is vested in the senior male member of the family. He is the most dominant member and controls the internal and external affairs of the family. The senior female member by virtue of being the wife of the male head shares his power so far as the women of the family are concerned. (4) The familial relations enjoy privacy over marital relations. Early age marriage is advocated to ward off any threat from marital relationship.

The merit of the joint family system is that it is based on the motto: "unison is strength." There is a sharing of responsibilities practically in all matters which gives the family a greater economic and social security. It provides economic and social security to the old, the helpless and the unemployed. It pools its income to help the young through school, to pay for a marriage or begin a commercial venture. It offers many of the services and advantages which an industrial society offers through more impersonal governmental, educational and financial agencies.

3 THREE GENERATION FAMILY

The three generation family is confused with the joint family. It is fairly common in the west. This tends to be a household where there are representatives of three generations. It occurs usually when young couples are unable to find separate housing accommodation and continue to live with their parents and handrear children. Thus, representatives of three generations related to each other by direct descent live together.

Functions of the family

The functions of the family have been stated as follows:

(1) Residence: One of the major social functions of the family is to provide a clean and decent home to its members. In the west when a man marries, he separates from his parents and sets up his own home. In India, it is the prevalent custom among the Hindus that the married couple should reside in the house of the parent. There are two types of residence – patrilocal and matrilocal. In the case of patrilocal residence, the wife goes to the house of the husband; in the matrilocal residence, the husband goes to live in the house of the wife. (2) Division of labour: In primitive societies, the roles and functions performed by people in family groups were rather well defined. The male had the role duty to earn a living and support the family. The female had the total responsibility for the day to day care of children and running of the household. In industrialized and urbanized communities, there is less marked distinction between the functions of men and women. On the other hand, there has been an increasing coming together and sharing of responsibilities by men and women. The young woman in India now-a-days brings to marriage not only a dowry but a professional or semi-professional education and she seeks a professional career. This is another new feature of the modern family. The steady enlargement of the freedom of wives, and even children in the family, is leading towards a "communal family" where all its members play a part in its management. (3) Reproduction and bringing up of children: This is a very important function of a family. The mother takes absolute care of the infant and children up to a certain age. The father provides education and teaches the child the social traditions and customs. (4) Socialization: The family is a bridge between generations and between father and sons. It is the transfer point of civilization. The cultural patterns relating to eating, cleanliness, dress, speech, language, behaviour, and attitudes are all transmitted through the family. (5) Economic functions: The family implies economic partnership for the family and the progeny. The inheritance of the property and the ownership and/or control of certain kinds of property like the farm, shop or dwelling are controlled by the family. Eventually the property is handed down to the children. (6) Social care: The family provides social care by (a) giving status in a society to its members, (b) use of family names where it occurs. Some have a strong feeling of kinship which they belong to a particular family – it denotes some kind of association with someone distinguished in history in the particular society, (b) protecting its members from insult, defamation, etc., (c) regulating marital activities of its members, (d) regulating to a certain extent ethical, religious and general social activities, (e) regulating the relations through invest taboos.

FAMILY IN HEALTH AND DISEASE

Anyone who is concerned with medical practice or community health activities will come to know that family is ultimately the unit with which one has to deal. The family is a group of biologically related individuals. It is a pretty universal picture in all societies. Family performs many functions. There are certain functions which are relevant to health and health behaviour, and are important from the medical-sociological point of view.

1 CHILD REARING

One of the important functions of the family with which medical and community health workers are concerned, is the physical care of the dependent young in order that they may survive to adulthood and perpetuate the family. The way in which child rearing is undertaken differs enormously from society to society, and from time to time, depending upon factors such as capital resources, level of knowledge, state of technology and system of values. It is important to note that patterns of child care (e.g., feeding, nutrition, hygiene, sleep, clothing, discipline, habit training) are passed on from one generation to another. In many societies, child care is socially determined by tradition.
ideas people have about nutrition, exercise, sleep and clothing have a large societal component which varies from society to society and from time to time. For instance child care is more permissive in the East starting with the "on demand" schedule at mother's breast. In the West, child care is more rigid and confined to a set of rules. When the community health worker seeks to improve the health of the child, he meets several obstacles. These obstacles are the traditional ways which are supported by appeals to religion and other sanctions. For example, the problem of overcrowding is not merely a question of room space, but in many instances a question of sleeping habits, a part of a pattern of social customs which foster better relations between groups. Once again, variations between societies may be complex and difficult to change.

2. SOCIALIZATION

The second responsibility of the family is to socialize the "stream of new-born barbarians." It refers to the process whereby individuals develop qualities essential for functioning effectively in the society in which they live. It is a latent function. By socialization is meant teaching the young the values of society and transmitting information, culture, beliefs, general codes of conduct, by example and precept, in order to make them fit for membership in the wider society of which the family is a part. Organizations such as schools and religious places perform cultural functions for the introduction of the young into adult society. The young are persuaded, given punishments, rewards for good behaviour — all these vary from time to time. In some societies, the young are given freedom to develop into individuals who are freely able to take initiatives.

3. PERSONALITY FORMATION

This is even a more latent function. It is an area in which sociology comes closest to psychology. The capacity of an individual to withstand stress and strain and the way in which he interacts with other people is to a large extent determined by his early experience in the family, maintained with the father, mother and siblings who provide the earliest and most immediate component of the child's external environment. For the family is, as a "placenta" excluding various influence, modifying others that pass through it and contributes some of its own in laying the foundation of physical, mental and social health of the child.

4. CARE OF DEPENDANT ADULTS

(a) Care of the sick and injured: In all forms of society, adults may become dependent either through injury, illness or because of basic biological limitation for performing functions normally expected by adults. The attitude of the society in regard to individuals who need care and attention varies considerably. In some societies, there is a great deal of harshness in respect of those who are sufferers. Such individuals are excluded from the full range of benefits. The kind of illness is also of great importance in determining the attitudes of society where the illness arouses fear (e.g., leprosy). However, the family is charged with the responsibility of care of such individuals. The family is expected to provide the front-line care, particularly the mother. Much depends upon her understanding of illness and the extent she believes herself capable of providing nursing care. Studies have shown that the family does more nursing than the hospital, even in highly developed countries (20).

(b) Care of women during pregnancy and childbirth: From the public health point of view, care of women during pregnancy and child-bearing is an important function of the family. The attitude of society to pregnancy and child-bearing may have an important influence on the infant's death rates, premature and stillbirths, maternal morbidity and mortality. In many societies today, women are given financial help, maternity leave facilities, diet and nutritional supplements and decreased responsibilities during pregnancy and postpartum.

(c) Care of the aged and handicapped: An area of increasing importance, particularly in the western societies, is the care of the aged and infirm. The increased number of such people, have created new demands in terms of long term care and specialist facilities. Without the support of the family, no amount of medical care can succeed. In India, the joint family provides for such needs.

5. STABILIZATION OF ADULT PERSONALITY

The family is like a "shock absorber" to the stress and strains of life. The stress could be injury, illness, births, deaths, tension, emotional upsets, worry, anxiety, economic insecurity and the like. In such situations, the family provides an opportunity, both for adults and children, for release of tension so that the individual can attain mental equilibrium and strive to maintain a stable relationship with other people. The stress of modern living has increased the importance of mental illness as a public health problem. Alcoholism and narcotic addiction are also a reflection of this trend. Certain chronic illnesses such as peptic ulcer, colitis, high blood pressure, rickets, skin diseases are accepted as "stress diseases" having a prominent emotional element in their development. Thus the family has an important function in the stabilization of the personality of both adults and children, and in meeting their emotional needs.

6. FAMILIAL SUSCEPTIBILITY TO DISEASE

The members of a family share a pool of genes and a common environment and together, these decide their susceptibility to disease (22). Certain diseases such as cancer and heart disease are known to run through families. Schizophrenia, psychoneurosis and some forms of mental deficiency are also known to have a familial incidence. The family is often the playground also for such communicable diseases as tuberculosis, common cold, scabies, diapherisis, measles, mumps, rubella, chickenpox, dysentery, diarrhoea, and enteric fever. These diseases are known to spread rapidly in families because of the common environment which the family members share.

It is generally agreed that the incidence of congenital malformation is higher among offspring of consanguineous as compared with non-consanguineous marriages.

7. BROKEN FAMILY

A broken family is one where the parents have separated, or where death has occurred of one or both the parents. Dr. John Bowlby brought out clearly the concept of "mental deprivation" as one of the most dangerous psychiatric factors in child development (23). Separation of the child from its father (paternal separation) and separation of the child from both of its parents (dual-parental separation) are
important factors in child development. Children who are victims of broken families early in their childhood have been found sometimes to display in later years psychopathic behaviour, immature personality and even retardation of growth, speech and intellect (22). Children from these families may drift away to prostitution, crime and vagrancy.

8. PROBLEM FAMILIES

Problem families are those which lag behind the rest of the community. In these families, the standards of life are generally far below the accepted minimum and parents are unable to meet the physiological and educational needs of their children. The home life is utterly unsatisfactory. The underlying factors in most problem families are usually those of personality, and of relative lack of health, of poverty, illness, mental and emotional instability, character defects and marital disharmony. These families are recognized as problems in health, progress (23). When a change in such an environment is victims of prostitution, crime and vagrancy. Problem families may be found in all social classes but are more common in the lower social classes. The health visitor, the health inspector, the midwife, the social worker, the medical officer of health, all can render useful service in rehabilitating such families in a community.

The family therefore plays an important part both in health and disease — in the prevention and treatment of individual illness, in the care of children and dependent adults, and in the stabilization of the personality of both adults and children. In most societies the family is the fulcrum of health services (25). Medical schools are developing programs for family medicine because, as Florence Nightingale had said: "the secret of national health lies in the homes of the people."

CULTURAL FACTORS IN HEALTH AND DISEASE

All people, whether rural or urban, have their own beliefs and practices concerning health and disease. It is now generally recognized that cultural factors deeply involved in all the affairs of man, including health and sickness. Not all customs and beliefs are bad. Some are based on centuries of trial and error and have positive values, while others may be useless or positively harmful. Some of these cultural factors, however, have been unknown for centuries, and these are the way in which new programs are planned. Information about these factors, i.e., customs, cultural mores, habits, beliefs and superstitions is still woefully lacking. A brief account of the cultural factors relating to health and sickness, as observed in India, is given below:

1. Concept of etiology and cure

Broadly, the causes of disease, as understood by the majority of rural people, fall into two groups: (a) supernatural and (b) physical.

(a) SUPERNATURAL CAUSES: (1) Wrath of gods and goddesses. There are many gods and goddesses. A number of gods and goddesses are from the Brahminical tradition, while others are from the Hindu tradition. The Brahminical tradition believes in the existence of a God, and believes that certain diseases are due to the wrath of a god or goddess. Chickenpox is an outstanding example, it is known as Chikli Mata. Where the disease is considered to be due to the wrath of gods and goddesses, administration of drugs is considered harmful.

(b) PHYSICAL CAUSES: Physical causes are also considered to be responsible for certain diseases. Among these are: (1) The effects of weather: Exposure to heat during summer is responsible for an attack of food (heat stroke). The folk remedies consist of application of oil and oil on the soles of feet and administration of mango-pool (prepared by keeping unripe mangoes under hot ashes for a few minutes, and extracting the pulp in cold water) with a pinch of salt. (2) Water: Impure water is associated with disease. (3) Impure blood: Skin diseases, vizi. boils and scabies are considered to be due to impure blood. Eating neem leaves and flowers is considered to purify blood.

2. Environmental sanitation

(a) DISPOSAL OF HUMAN EXCRETA: Large percentage of people in rural areas use open fields for defecation. This practice is time-honoured and is considered harmless. The average Indian village is averse to the idea of latrines. He considers that latrines are meant for city dwellers, where there is no field for defecation. However, it is important that feces is infectious and pollutes water and soil and promotes fly breeding. Thus the problem of excreta disposal is bound up with water pollution.

(b) DISPOSAL OF WASTES: The average village is not aware that mosquitoes breed in collections of waste water. It is a usual practice to throw away garbage into a nearby river. This method of waste disposal (sewage) is invariably thrown in front of the houses where it is permitted to accumulate and decompose. Periodically it is removed to the fields and used as manure. The animal dung (cow dung) is allowed to accumulate. It is used sometimes as manure and often times pressed into cakes, sun-dried and used as fuel. (c) WATER SUPPLY: The well occupies a pivotal place in the cultural environment of villages. It also is the common meeting place of men and women of the village, when they go to draw their supply of water. It is a place where people bathe and wash their clothes. It is a place where animals are washed and given a drink. These cultural practices lead to the pollution of well water. Tanks and ponds are used for washing, bathing, ablution and sometimes even as a source of drinking water. Some rivers are considered "holy". People on pilgrimage to these rivers to have a dip. They not only have a dip but drink the raw water which they consider sacred. Samples of "holy water" are bottled and carried over long distances for distribution among friends and relatives. Epidemics of cholera and gastroenteritis have been due to these cultural practices. Step-wells are associated with guinea worm disease. (d) HOUSING: Rural houses are practically the same all over the country. They are usually kutchas and
damp, ill-lighted and ill-ventilated. For reasons of security, no windows were provide, and if at all one is provided, it is merely a small hole. Absence of a separate kitchen, latrine, bathroom and drainage are characteristic features of an average rural house. Animal keeping is very common in villages. Infrequently, human beings and animals live under one roof. Houses are generally kept clean inside, regularly white-washed or plastered with mud and cowdung.

3. Food habits

Food habits have deep psychological roots and are associated with love, affection, warmth, self-image and social prestige. The diet of the people is influenced by local conditions (e.g., soil, climate) religious customs and beliefs. Vegetarianism is given a place of honour in Hindu society. Even among vegetarians, the pattern of eating is not the same; some do not take onions and garlic on religious grounds. Muslims abhor pork, and Hindus beef — these food habits have a religious sanction from early days. The concept of 'hot and cold' foods is widely prevalent in the country. Foods such as rice, fish, eggs, and jaggery are considered to generate heat in the body; foods such as curd, milk, vegetables and lemon are considered to cool the body. These concepts are encountered by the modern physician when treating disease. Adulteration of milk is a common practice. Although the motive is economic gain, a deep-rooted belief is also responsible for this practice, i.e., if pure milk is boiled, the milk secretion of the donor animal may dry up. Muslims observe huts during Ramadan and Hindus on several occasions. These fasts are considered important adjuncts to religion. Drinks and drugs are among the food habits of the people. Alcoholic drinks are tabooed by Muslims and high-caste Hindus. Ganja, bhang and charas are frequently consumed by drug addicts; these habits are now spreading into the general population, especially the younger generation. Eating and drinking from common utensils is considered a sign of brotherhood among Muslims. Hindu women often take food left over by their husband. In some societies, men eat first and women last and poorly. Some people do not eat unless they have taken a bath. Thus food is a subject of widespread customs, habits and beliefs, which vary from country to country, and from one region to another.

4. Mother and child health

Mother and child health is surrounded by a wide range of customs and beliefs all over the world. Marriage is universal in Indian society, and the family is incomplete without the birth of a male child. The absence of these implications is the context of the country's population problem and male : female ratio. The various customs in the field of MCH have been classified as good, bad, seerimented and uncertain. (1) Good : Customs such as prolonged breast-feeding, oilbath, massage and exposure to sun are good customs. (2) Bad : These vary from society to society. For example, some foods (e.g., eggs, meat, fish, milk, leafy vegetables) are forbidden during pregnancy in some parts of the country. In rural areas, most deliveries are conducted by the traditional untrained dai or birth attendant whose methods of conducting delivery are far from safe. The villagers have great faith in her. In some parts of the country, the child is not put to the breast during the first 3 days of birth because of the belief that colostrum might be harmful; instead, the child is put on water, and sugar solution. Breathing of the skin, administration of opium and drastic purgatives are all bad customs. The net result of these customs is high infant mortality and morbidity. (3) Unimportant : There are certain customs and practices, viz., the use of toothbrush and toothpaste, application of oil or paste of turmeric or the anterior fontanellic. (4) Uncertain : Sometimes, it may be difficult to say whether certain customs are harmful or beneficial. The practice of applying kajal or black soot mixed with oil to the eye-lids partly for beautification and partly for warding off the effects of "evil" demons, seems to be beneficial for transmitting trachoma and other eye infections. A knowledge of the local customs and beliefs is therefore very important for it will help in the health status of mothers and children. This is part of social pediatrics.

5. Personal hygiene

Indians have an immense sense of personal cleanliness, much of which is closely interwoven with ideas of ritual purification. Ritual purification is an act of purifying parts of the body, usually involving religion or magic, with the sequence established by tradition. (1) Oral hygiene : Indians are very particular about oral hygiene. Many people in the countryside use twigs of neem tree as a toothbrush; some use ash; and some charcoal. The educated and those who have come in contact with urban life use toothbrushes. Eating pan leaves smeared with lime with or without tobacco is a common social custom. (2) Bathing : Bathing naked is a taboo. Apart from regular baths of which Indians are very fond, there are baths fixed on special occasions. The women after menstruation must have a purifying bath; after childbirth, there may be two or three ceremonial baths, the time for which is fixed upon the advice of the priest. The practice of an oil bath is a good Indian custom. Womenfolk in the countryside use a paste consisting of gram, mustard oil and turmeric powder and rub it on the body before a bath. Thus, bathing is a ritual in India. (3) Shaving : This is done by the traditional barber (nai) in the countryside. He does not sterilize the instruments used, as he does not have any idea of mica-organisms. (4) Smoking : Smoking bubble-bubble is a social custom in some parts of the country. It can spread tuberculosis. Smoking with the burning end of the cigarette in the mouth, which is a common custom among villagers in Andhra Pradesh, is associated with oral cancer. The 1977 Report of the Royal College of Physicians of London (26) on the effects of smoking and health provides useful summary of information on the diseases now known to be associated with smoking — cancer of the lung, chronic bronchitis and possibly any respiratory attempt activities. Among patients with peptic ulcer who smoke have a higher death rate than those who do not. A mother's smoking during pregnancy may retard the growth of the foetus. (5) Purdah : Men and this and some high-caste Hindu women observe purdah. The incidence of tuberculosis is reported to be high amongst those who observe purdah, which also deprives them of the beneficial effect of the smoking. (6) Sleep : Many people in the villages sleep on the ground for reasons of poverty, and they are exposed to insect bites. (7) Wearing shoes : The transmission of hook-worm disease is associated with bare feet. Many villagers in South India do not wear shoes. (8) Circumcision : This is a prevalent custom among Muslims, which has a religious sanction.

6. Sex and marriage

Sexual customs vary among different social, religious and ethnic groups. For certain religious groups menstruation is a
time of uncleanness when women are forbidden to pray or have intercourse; orthodox Jews are forbidden to have intercourse for seven days after the menstruation ceases (27). These customs have an important bearing in family planning. Marriage is a sacred institution. It is the usual social custom in India to perform marriages early. It is considered a sound and desirable practice, because late marriages may create problems in a joint family system. Because of the universality of marriage in India problems of unmarried mothers and of illegitimate births are less frequent in the western countries. The mean age at marriage in India is 54 years in the case of boys and 21 years in the case of girls. There are differences in marriage-age by caste, females of the depressed classes have lower mean age at marriage. Child marriages are fortunately disappearing. Monogamy is the most universal form of marriage. Polygamy (marriage of one man with several women) prevails in certain communities. Polyandry (marriage of several men with one woman) is found among the Todas of Nilgiri hills, the inhabitants of Jaunsar Bawar in Uttar Pradesh and the Nayars in Malabar coast. The high rate of venereal diseases in Himachal Pradesh is attributed to the local marriage customs.

THE COMMUNITY

"No man is an island". From the time of birth until death, all normal human beings are part of a group, the family or community. The characteristics of a community are:

1. The community is a contiguous geographic area
2. It is composed of people living together
3. People cooperate to satisfy their basic needs
4. There are common organizations, e.g., markets, schools, stores, banks, hospitals.

In other words, a community is a network of human relations that provides a unit of society. It is the place where our home is located; children are educated; sick people are treated and individual basic needs and desires are met.

Structure of society

1. Caste: Indian society is mostly based on caste system. There are further sub-divisions into sub-castes. Each caste is governed by certain rules and regulations relating to food, drink, marriage, social contact and rituals. Castes follow a definite occupation. In urban areas, the caste system is less rigid. The Indian caste system is supported by religion.
2. Income: On the basis of income, people have been grouped into classes - upper, middle, and lower classes. People in the upper class enjoy better standards of life.
3. Occupation: Occupation has also been adopted for classifying people. In India, there is no satisfactory occupational class system.

Rural societies

India is a land of villages. There are 40,867 villages. Out of every 1,000 population, 690 live in villages (as per 2011 census). The average population of an Indian village is about 550 or 100 families. The villages are self-sufficient units for most of the routine requirements of its people. The rural people depend primarily upon agriculture. Caste, religion, ritual, kinship, marriage, and economy are some of the important aspects of Indian village society.

Urban societies

Towns and cities comprise the urban society. They are relatively large, dense, and permanent settlements of people. According to the 2011 Census, there were 7,235 towns and cities in India. It has been said that civilization means the city and the city means civilization. The city represents the way of living of man in modern age. The occupational pattern of the urban people is different. They depend less on agriculture. There is an occupational diversity. The social life is impersonal and less intimate. Cities are the melting pots of races, people, and cultures. Traditional patterns of belief and behaviour tend to be broken down. New ideas and patterns of behaviour spread which further speed to villages.

Social mobility

Indian society is rigidly based on caste system. There is little social mobility, i.e., people do not change their caste or religion. In other words, Indian society is a "closed-class" system. There are certain societies where movement of the social ladder is unrestricted, on the basis of achievement or gaining wealth. Open class societies are therefore more progressive where people according to their ability can go up the social ladder. In closed-class system, it is difficult to make returns without meeting resistance of the people.

SOCIAL CLASS

People in a community are differentiated by certain characteristics which they bear. These may be personal characteristics such as age, sex, marital status, place of birth and citizenship; economic characteristics such as occupation, type of activity; cultural characteristics such as language and religion; and educational characteristics such as literacy and level of education. In Indian communities, especially in rural areas, caste is an important basis of social differentiation. The caste groups are hierarchal and carry different degrees of social prestige, which is correlated with a host of other socio-cultural factors.

Although defined differently in different societies and by different commentators, social class is closely bound up with economic status, level of education, way of life, attitudes and expectations, and exposure to different types and degrees of stress. More important, it seems to have a direct bearing on the external resources and internal mechanisms available to individuals in attempting to deal with health problems.

Social scientists have used occupation widely as a means of determining the level of social standing of an individual in a community, because occupation has an enormous importance in all societies for understanding human behaviour. In urbanized and industrialized communities, where there is a substantial division of labour, occupation is a major determinant of: (1) Economic rewards; (2) Castes and occupation is an important determinant of authority which the individual has over other people; it spills over into his life itself, his pleasures and other activities, through control of purchasing power. Those who receive higher economic rewards tend to be vested with greater authority. For example, a person who is a judge exercises authority not only in the courts but commands respect from other people. His position enables him to acquire authority. (3) Extent of obligations; The
extent of obligations demanded of individuals by the rest of the community will be determined by the occupation he holds. One who holds a high place occupationally has greater obligations. (4) Degree of status: Closely allied with the occupational role is the degree of status and standing of the individual in the community. For example, medical practitioners in India enjoy a higher status in society than others. The occupation itself will give the person status irrespective of personal characters, age, and experience. (5) Values and life styles: The occupation of an individual very largely will determine many of the values the individual has, the things he feels worth pursuing, his life goals, his life style, his pleasures, friendships and relationships with others. Therefore, occupation is widely used as a measure of social differentiation. In technologically advanced countries, occupation tends to range in a hierarchy — those who have high economic rewards have a higher level of prestige than those who are placed lower in the social hierarchy.

**Occupational classification**

There are several occupational classifications, but none is satisfactory. Some sociologists have graded occupations in a hierarchy and then divided them into broader "prestige" categories. They have found a high degree of similarity between social grading of occupations in India and England. The oldest such classification that is epidemiologically useful is the Registrar General's occupational classification in England and Wales. All occupations are classified into five groups. Social class III is further subdivided into non-manual and manual groups:

I Professional occupation
II Intermediate occupation
III N Non-manual skilled occupation
III M Manual skilled occupation
IV Partly skilled occupation
V Unskilled occupation.

**Limitations of occupational classification**

Occupation is a useful measure of social differentiation particularly in communities highly industrialised and urbanised. We all tend to compare, for example, different social classes in relation to mortality and morbidity. But, there are certain limitations in using social classification based on occupations alone. These may be stated as follows: (1) Heterogeneous grouping: Each social class is a heterogeneous grouping of a wide variety of occupations. There is an assumption that these occupations are related to each other, which in fact, is not so. The people in each social class differ not only occupationally, but also in respect of educational status and family background. We have to recognize that categorization into social classes is merely one of convenience. (2) Occupational mobility: People sometimes change their occupations. This occupational mobility can lead to discrepancies in using social classes correctly over a period of time. Social classes themselves are subject to change. Certain occupations are promoted in social hierarchy and some demoted. For example, the Registrar General of England promoted university teachers from class II to class I and demoted company directors from class I to class II during the decade 1951-1961. Such changes in social classification may invalidate their comparative use over time. (3) Women: There are differences in classifying women alongside men. Some occupations are exclusively occupied by males and some by females. There is also sometimes ambiguity in the nomenclature of occupations occupied by men and women. If a man describes himself as a secretary, it is a highly paid occupation; if a woman describes herself as a secretary, it is usually a position in an office in a low capacity. Despite of these limitations, social classification by occupation is an effective tool for examining various kinds of data related to people. Much research in social medicine in recent years has centred round social class and disease prevalence.

**Other measures of social differentiation**

There are other measures of social differentiation which may be of greater use or significance than occupation. These are:

(1) Education: It measures the inculcation of values, knowledge and achievements of the individual. (2) Income: Another important way of distinguishing people is by the amount of income or wealth. Here again, there are difficulties because people have great reluctance to talk about their income truthfully. (3) Purchasing power: This may be of more importance than occupation in classifying people. (4) Religion: This is another important attribute of the individual which may have tremendous bearing on the health of the people. An examination of infant mortality among Christians, Hindus and Muslims in India revealed a low rate for Christians, a high rate for Hindus and highest for Muslims. These differences are attributed to religion which has a bearing on the socio-cultural patterns of living involving age-old habits, customs, and traditions affecting cleanliness, eating, clothing, child care and almost every detail of daily living. (5) Rural and urban: There are differences in the health and sickness status of people living in rural and urban areas. Rural and urban people differ in their life-style, opinions and values, which have a bearing on the health and sickness status. To sum up, it may be stated that each of these measures which may be employed for social differentiation have a "snag" two and therefore each must be examined critically and used with discrimination depending upon the subject matter of the inquity.

**Socio-economic status scale**

Socio-economic status has been defined as the position that an individual or family occupies with reference to the prevailing average standards of cultural and material possessions, income, and participation in group activity of the community. The social status may be inherited, but in modern society, it is achieved on the basis of occupation, income, type of housing and neighbourhood, membership of certain associations and organizations, material possessions, etc.

There have been many attempts at developing scales for measuring socio-economic status. Hollingshead in USA employed three variables, viz. education, occupation and residential address for measuring socio-economic status. Kuppuswamy (1978) in India prepared a scale based on education, occupation and income which are the three major variables contributing to socio-economic status in urban areas. Similar scales have also been prepared by Pareek and Kulshreshtha (1979) for use in rural and urban areas. Kuppuswamy's scale is fairly widely known. The modified version of the Kuppuswamy's socio-economic status scale for the year 2007 is given in Table 2. The income scale has been recalculated using All India Average Consumer Price Index for the industrial workers for the year 2001 as the new base year (30, 31).
Kuppuswamy's socio-economic status scale

Wealth Index (32)

One of the background characteristics used in the National Family Health Survey-III was an index of the economic status of households called the wealth index. The wealth index has been developed and tested in a large number of countries in relation to inequalities in household income, use of health services, and health outcomes. It is an indicator of the level of wealth that is consistent with expenditure and income measures. The economic index was constructed using the following household asset data and housing characteristics: household electrification, type of windows; drinking water source; type of toilet facility; type of flooring; material of exterior wall; type of roof; cooking fuel; household ownership; number of household members per sleeping room; ownership of a bank or post-office account; and ownership of a mattress, a pressure cooker, a chair, a cot/bed, a table, an electric fan, a radio/ transistor, a black and white television, a colour television, a sewing machine, a mobile telephone, any other telephone, a computer, a refrigerator, a watch or clock, a bicycle, a motor scooter or scooter, an animal-drawn cart, a car, a water pump, a thrasher, and a tractor.

Each household asset is assigned a weight (factor score) generated through principal components analysis, and the resulting asset scores are standardized in relation to a normal distribution with a mean of zero and standard deviation of one. Each household is then assigned a score for each asset, and the scores were summed for each household; individuals are ranked according to the score of the household in which they reside. The sample is then divided into quintiles i.e., five groups with an equal number of individuals in each. In National Family Health Survey-III, one wealth index has been developed for the whole sample and for the country as a whole. Thus, at the national level, 20 per cent of the household population is in each wealth quintile although this is not necessarily true at the state level. Table 3 shows the wealth quintiles in India according to residence as urban and rural areas and in major states (22).

As shown in Table 3 forty-eight per cent of the population in urban areas is in the highest wealth quintile; in contrast only 7 per cent of the rural population is in the highest wealth quintile. The distribution of the population across wealth quintiles shows large variations across states, with Delhi (70 per cent) and Goa (65 per cent) having over one-half of their populations in the highest quintile and Chhattisgarh, Orissa, Bihar, and Tripura, having only about one-tenth or less of their populations in the highest quintile. In Jharkhand, half of the population falls into the lowest wealth quintile. By contrast, in about half of the states, less than 10 per cent of households are in the lowest wealth quintile.

Social class and health

There are a large number of studies linking social class to incidence of disease. Income, occupation and education which are the major components of most measures of social class are also each generally positively correlated with health status. It adds to the conviction that social class affects health. Individuals in the upper social classes have a longer life expectancy, less mortality and a better health and nutritional status than those in the lower classes. Diseases also have been shown to affect people at various social levels differently. For example, coronary heart disease, hypertension, diabetes all have been shown to have a high incidence in social class I and a gradual decline in incidence in the other social classes. Diseases of skin, eye and ears, diarrhoea and dysentery have also shown a higher incidence in the lower classes, which can be ascribed to the poor state of physical environment in which they live. Social class differences in mental illness have also been reported infant mortality, general mortality, maternal mortality are all related to social class. To serve as an illustration (Table 4), the National Family Health Survey-III (2005–06) conducted in India shows the glaring differences in infant mortality rate among the households belonging to various wealth index brackets. Infant mortality rate is high (about 70.4 among the lowest wealth index households and is lowest (about 29.2) among the highest wealth index households.

Source: (22)

Social class differences have also been observed in the family structure, and utilization of medical and health services. Families in the lower classes are bigger in size, women marry early and bear more children. The upper social classes are characterized by small sized families and fewer children. Individuals in the lower social classes have been found to make less use of the hospital facilities, consult the doctors less often and are less likely to utilize preventive health services such as prenatal and postnatal care, general check-ups and immunization services. Social classification therefore provides an important means of studying health and disease phenomena in communities, and has proved an effective tool.

Factors involved in social class differences in health and disease

It is the first concern of those in preventive medicine and those who provide medical care service to know why there are differences in mortality and morbidity from particular diseases in certain social classes. Many factors may be involved, the following are some: (1) Physical environment: Differences in mortality and morbidity may be due to differences in physical environment, e.g. housing, safe water, access to clean air, etc. People in the upper social hierarchy enjoy better physical facilities than those in the lower rungs of society. (2) Differences in services provided:

There are differences in the availability of services for different social groups. So far as general practitioners are concerned, some areas are relatively underdoctored as compared to others. On the whole, it seems the underdoctored areas are the areas where a substantial proportion of individuals live. (3) Material resources: Differences in material resources, e.g., income, wealth and possession of tools which can promote or help achieve better health also intervene in the occurrence of disease or in the maintenance of health status in different social groups. (4) Genetic endowment: People in one social class tend to marry in the same social class. The differences in genetic endowment may also influence one's liability to disease. (5) Educational status: The educational level varies in different social classes. The ignorant and the illiterate are likely to have much difficulty in pursuing measures which may conclude to good health. (6) Attitude to disease: The attitude of people to health and sickness may vary in different social classes, which may account for differences in distribution of disease in the social classes. There are people who regard illness as a punishment and there are others who regard that illness is due to natural causes. There are people who diagnose illnesses themselves and there are others who seek early medical aid. The attitudes of people therefore vary in different social classes. The continued differences which show up in many studies of morbidity and mortality and use of medical services are due to the persistence of substantial differences in social class. These is a great field for exploration of value systems, the significance of illness to families in different classes. The aim of preventive medicine should be to reduce the social class differences in health and disease.

HOSPITAL SOCIOLOGY

Hospitals are among the most complex organizations in modern society. They have been in recent years an examination from a sociology point of view of hospitals, of medical personnel and of the utilization of medical services. The modern hospital is a social universe with a multiplicity of goals, profusion of personnel and an extremely fine division of labour. The care requires the patient to make a set of demands for those whose lives it seldom brings them into direct contact with sick people. The patient is the hospital's client (33). This complex character of the hospital has fascinated the social scientists as a compelling scene for the study of human behaviour.

Social structure of a hospital

A hospital is not a static organization. It is subject to change in structure and function depending upon the changes which occur in the community. The structure and functions of the hospital have changed considerably to what they were 100 years ago. Historically, the hospital was more nearly a place of refuge for the sick and homeless, than a place for medical treatment. It was a charitable institution where one went to die rather than to be cured (33). In contrast, hospitals today are concerned with active medical treatment, mobilizing all that is latest in medical sciences to produce a cure. In the 19th century, hospitals were occupied by poor and old patients. Hospitals today are occupied by all classes of people. The shift in the type of patients occupying hospitals has led to a new doctor-patient relationship. There is an increasing demand for higher academic qualifications which was not typical of the earlier medical organization of the 19th century. This has led to an increasing complexity of specialization within the medical
profession and no doctor today can provide single-handedly all the skills and facilities needed for treatment.

The other functions performed by hospitals are teaching either medical, nursing personnel and research designed to increase medical knowledge in which the patient is of secondary importance. The rural and district hospitals concentrate mainly on patient care. Teaching should take precedence over research in teaching hospitals.

The hospital today is a system of increasing complexity — it is a hotel and a school, a laboratory and a stage set for treatment — employing a large number of medical and paramedical personnel unlike the earlier hospitals in which very few professional groups were involved. At heart the hospital is like a federal system with several departments each enjoying considerable autonomy and discretion in its management of work. The great challenge is one of coordination (33). It requires an administrative machinery to run the hospital smoothly and to avoid conflicts between administrative and professional staff, and between professionals. If a sizable portion of a group is dissatisfied, the system will break down.

The democratic ideal has certainly not yet been achieved in medicine. The structure of the wards, semi-private rooms and private rooms in hospitals is an obvious reflection of class lines. The service of the doctor in his private chamber tends to differ from that given in a public clinic not only in the time spent for case examination but in interpersonal attitudes. The public has come to expect hospitals to give tender, loving care to every patient every day (34).

It is said that each hospital has a "personality" of its own — a tempo of work and an emotional atmosphere peculiar to a given hospital, its traditions, its community of staff and patients. The nature of the staff relationships will influence the staff-patient relationships and consequently the outcome of therapy. It is for this reason there are different atmospheres in different hospitals. Some have a good name, others a bad name.

Medical profession

There has been an examination from a sociological point of view of the medical profession. The medical profession, like any other occupational group is distinguished by certain characteristics. There is a professional body which controls the right to practice. The licence to practice is embodied in the legislation, and is given to those who have reached a level of competence which is considered minimum. In India, the Indian Medical Council Act was passed in 1933 to establish uniform standards of medical education in the country. A revision of the Act was made in 1956, which provides, in addition, for the maintenance of the All India Medical Register. The State Medical Councils confer the right to practice and certain standards of practice and personal conduct are imposed upon its members. There is great insistence of maintenance of confidentiality, and right to practice medicine is withdrawn if there is professional misconduct. In other words, the State is regulating the relationship between professional men and their clients. Some of the possible conflicts in the medical profession may stem from the rules and regulations to which they are bound. The obduracy of private practice, by Government doctors is an example of recent conflict.

Medical care — an Industry?

The traditional physician was a self-employed small businessman, with many of the same problems, goals and attitudes as other small businessmen. His practice was "soo-pRACTICE" based on "beer-for-service." Significant changes have taken place in the practice of medicine. The introduction of new diagnostic and therapeutic techniques require not only large capital investment but also skilled team of personnel. A large number of non-medical personnel are also involved in producing medical care. Society is being increasingly asked to subsidize medical education and medical care. There is a rapid development of insurance and other types of pre-payment. Now it is a national policy in many countries to make the best of known medical care available to all who need it regardless of economic status. Medical profession with its knowledge, experience and dedication is leading the way to developing better systems of health care for all. In economics, an industry is defined simply as a collection of individuals and institutions engaged in the use of similar scarce resources to produce similar goods or services. Sociologically speaking, medical care has the features similar to, big industry (35).

Specialization (36)

The vast increase of medical knowledge during the 20th century has contributed to specialization in medicine. There are at present no less than 20 recognized specialties and many more sub-specialties. A specialist is defined as one who learns more about less and less. He is concerned with a particular organ or part of the body as opposed to the traditional general practitioner or "family doctor" who is concerned with the "whole person" or even the family.

Specialization has created problems for the traditional doctor-patient relationships. The specialist does not establish close relationship with the patient. As a consultant, he is less likely to maintain a continuing relationship with the patient. It is difficult for him to give the patient the requisite emotional support and understanding that is needed and which is the essence of a good doctor-patient relationship. Besides, specialization has encouraged jurisdictional disputes between one specialty and another and between specialists and generalists.

In short, specialization divides both doctor and patient; places strain on the traditional doctor-patient relationship; contributes to depersonalization. The social role of medicine with the assistance of the humanities and social sciences is forgotten. Over-specialization can lead to a lopsided development of the health services. Sociologically, are paying increasing attention to an examination of the medical value system, the forces behind specialization, and selective factors in medical career choices (36).

Doctor-patient relationship

An important area of medical sociology is doctor-patient relationship in which tangible social factors are implicated. The patient comes unprepared to a doctor and enters voluntarily into a contract in which he agrees to follow the doctor's advice. By virtue of his technical superiority, knowledge and skill, the doctor exercises an authoritative role and issues "orders" to his patient. Some individuals may not be prepared to invest the problem with full authority; this may lead to conflict between the doctor and patient.

Besides technical competence, the doctor must know how to communicate with his patient. In fact, a successful doctor is one who knows how well to communicate with his patient. In this regard, three levels of communication have been described (37): (1) Communication on an emotional plane: The doctor must give a sympathetic ear to the complaints.
made by the patient and his relatives. This is necessary to establish a quick rapport. The reason why folk medicine is successful is because the patient and his relatives feel they can talk more freely to a folk medical practitioner than with the modern physician. The interpersonal relationships between villagers and folk practitioners on one hand, and the villagers and the practitioners of modern medicine on the other hand are considerably different. (2) Communication on a cultural plane: Secondly, the doctor should be aware of the general concepts of culture and social organization of the community with which he is dealing. This enables him to handle his dealings with patients. The reason why the indigenous and folk systems of medicine are successful in the rural areas is because they are part of the total way of life of the people: treatment is based mostly on charity, and payment to the physician may be in kind, and the medicines are prepared from ordinary plants common to the region. All these are appealing to the common man. Against this background, the western system of medicine is alien to the cultural patterns of the rural folks. To be successful, the modern doctor should couch his scientific advice in terms which fit an already existing cultural pattern. Then there is a great chance that this advice will be followed. For example, in communities where diseases and medicine are classified as hot and cold, it might be helpful for the doctor not to challenge his belief openly. A mere statement to a patient that the medicine is “hot” and will help to cure a “cold” disease may make for increased confidence. Anthropologists have therefore stressed the importance of understanding the community as a whole, its general cultural patterns and its social and political structure, and the native concepts of health and disease. (3) Communication on an intellectual plane: Practitioners of modern medicine come from well-to-do families. By their education and training, they tend to be sophisticated. This leaves a wide gap between the intellectual level of the practitioners of modern medicine and the illiterate masses. In other words, there is an enormous “social distance” between the two groups. A successful doctor is one who reduces this distance and is able to communicate with his patient. This may be done with confidence. A most important component of doctor-patient communication is humour. It is the best icebreaker for the patient from anxiety and pain. The doctor who is able to communicate with his patient on these three planes is bound to give maximum psychological satisfaction to his patients. The other qualities which make the reputation of a doctor are his "need" for money, differential treatment between the rich and poor and lack of a sympathetic and friendly attitude. The patient can challenge the doctor's professional adequacy if the doctor does not know how to communicate. Patients who do not behave according to the doctor's expectations are often labelled as "un-cooperative."

Doctor-nurse relationship (38)

Medicine and nursing have common goals - the preservation and restoration of health. Yet their roles in achieving these objectives are not identical. The primary role of medicine comprises diagnosis and treatment - the "cure" process. In contrast, the primary role of nursing lies in the "care" process - consisting of caring, helping, comforting and guiding.

In the medical-care team, the physician tends to be autocratic and looks upon the nurse primarily as his helper following his orders and carrying out whatever he chooses to delegate. Because of the authoritarian role of the physician, the role of the nurse in guiding, helping and comforting the patient is largely unrecognised. Now more that new technology is advancing, the nurse is asked increasingly to take up tasks instrumental to diagnosis and treatment. In effect, many of the patient’s psychosocial needs persist, unidentified and unmet.

Currently, leaders in both the professions are exploring new approaches and roles with a view to provide improved patient care (36).

The sick role

To be ill is more than a medical condition. The sick person has to behave in certain prescribed ways. He comes unbidden to a hospital. As he strips off his clothing, so he strips off his customary identity in the world. He becomes subject to a time schedule and a pattern of activity not of his own making. He becomes passive for most part. He may even become child-like (33). Four aspects of the sick role have been described: (1) The sick person is exempted from his normal social responsibilities depending upon the severity of his illness. (2) He needs to be cared for. (3) Sick role is regarded as a misfortune. (4) The sick person is obliged to seek competent medical care, and to cooperate with the doctor in the process of getting well. A typical sick role is temporary, but some patients prefer a prolonged sick role in order to escape everyday responsibilities.

Medical social work

Medical social work had its beginning in England in 1895 with a social worker, known as "Almoner" was appointed at the Royal Free Hospital, London. Later on in the United States, the term was expanded into medical social work. In the UK, medical social work, has grown into an important field of social work, and an integral part of medicine. Medical social work uses "case work" as its main technique to find out the social background of illness; this information helps the doctor in arriving at a social diagnosis, treating illness and estimating the prognosis. The purpose of medical social work is to help sick people - (individual by individual), both through the best use of the patient's capabilities and community resources in matters of personal and social adjustments in the community, including rehabilitation. The person who can best do this type of work is one who had special training in social case work, the medical social worker. 

Medical social worker

The medical social worker is a paramedical worker who has been trained in social case work, and in the art of interviewing people. There are many situations, in medical and public health organisations, where medical social workers are being employed, e.g., hospitals, tuberculosis clinics family planning clinics, cancer control centres, mental health, maternal and child welfare, school and university health services. The medical social worker forms a link between the institution where he is employed and the community. The principal work of the medical social worker is to visit the family and probe into the personal, economic and social causes of illness and collect social history of the patient with a view to supplement the medical history. The medical social worker also tries to secure help to the patient through the community resources. In chronic disabling illnesses like tuberculosis, leprosy and polyomethyls, the medical social worker helps in the rehabilitation of the patient. The medical social worker is now recognized as an
essential professional colleague of the doctor in the analysis and correction of the social and emotional factors and is increasingly relied upon for supplying information that is of fundamental importance in formulating the complete diagnosis and in directing the treatment of many patients. A medical social worker bears the same relationship to the effectiveness of social medicine, as does the nurse to clinical medicine.

From medical ethics to social ethics (39)

Since antiquity, the doctor/patient relationship has been governed by systems of medical ethics derived from the Hippocratic, Chinese, Indian, and other traditions. All held that the patient’s good transcended other considerations. The physician determined what was the patient’s good. Modern codes have added a social dimension, a responsibility for the health – the good of society and humanity in general – and a concern for justice. “Health for all”, with its emphasis on social justice, is in the equitable allocation of resources and on the responsibility of communities and individuals for their own health, is an expression of this change, and thus represents an ethical as well as a social goal.

The transformation of medical ethics has been stimulated partly by the progress of medical biotechnology and partly by profound social changes, associated with a recognition of human rights and freedoms, and of individual autonomy. Many medical choices can no longer be made purely on the basis of medical science. The emphasis on the social good has confronted lay individuals, whether policy-makers or patients, with ethical decisions and choices, requiring them to share with or often replace the physician or the scientist in determining what is ethically plausible and good, to balance the patient’s interests with those of society.

The explosion of expensive medical technologies, often of limited value to the patient, and the rise in people’s expectations, has accentuated the problem of making the best use of limited resources. Policy-makers must set priorities to guide the allocation of resources among health goals and between health and other social goals. They do so under many pressures – social, economic, political, technological and ethical. They are forced to make choices often with tragic consequences. Only full-scale medicine can use the full potential of modern biotechnology – for transplanting organs, for assisting reproduction, for postponing death, for reducing human suffering, for the medical care of the making up of human beings. In practice the policy-maker by controlling resources and trying to reflect the dominant values of society determines how much medicine can do, and even which patients may benefit. Thus the good of society and individual good may come into conflict.

For their part, individual patients today exercise autonomy and informed consent in deciding whether or not to accept or continue with treatment, even to continue to live, to become a subject of research, to permit the use of personal health data for study purposes, to be told – or not told – the truth, to permit the use of embryos, to donate organs and to withdraw life support systems.

Individuals, like communities, are subjects of research, such as trials of drugs or vaccines or epidemiological studies. Some living in deprivation or even oppression are liable to exploitation. Researchers have a particular ethical responsibility to safeguard the rights of such people and to observe scrupulously the ethical principles of beneficence, avoidance of harm, and justice.

Consumer Protection Act

Consumer rights have become an important issue. For the first time in India, the Consumer Protection Act 1986 provided consumers a forum for speedy redressal of their grievances against medical services. In the entire health care delivery system the most vital sector is the medical profession. Action against and disclosure of doctors is very important for its survival. Over the centuries the medical profession has been accorded respect by the public and yet the act of commercialization of the profession has eroded this faith.

As far as the professional services are concerned, the evolution of law has followed a set course. Under the general law, a member of a profession is required to show a standard of care which a person of that profession is expected to possess. In developed nations such as USA and UK, patients do not encounter many difficulties, as the courts have developed principles of law which give important rights to patients. In India, people were not going to Civil Courts freely because court fee is very heavy and there is long delay to get final verdict. It may take several years. Parliament has provided an alternative, a quick, efficacious and economical remedy. According to this Act, the decision should be taken within 3 to 6 months. There is no court fee payment and the person can plead his own case. More recently even ESI hospitals have been brought within the ambit of the Consumer Protection Act. COPRA is a piece of comprehensive legislation and recognizes six rights of the consumer, namely: right to safety; right to be informed; right to choose; right to be heard; right to seek redressal; and right to consumer education.

If a patient or the relations of a patient feel that the suffering or death of a patient is because of either negligence by the concerned doctor or the health facility, they can complain to the Medical Council of India or to the Consumer Court. The Medical Council of India, which is a statutory body created to monitor the medical profession has only certain jurisdiction. The court can only cancel the registration of the concerned doctor temporarily or permanently but cannot punish a doctor or give a compensation.

A complaint against the medical professional can be filed in the consumer court. It should contain all the details of the case, an expert certificate or opinion from the doctor of concerned specialty (stating the complaint is prima facie true and needs further investigation) and the compensation demanded. These courts can only give compensation. The monetary limits of the compensation that can be granted by the consumer courts are as follows: (a) District Consumer Court – Rs. 10,000; (b) State Commission – Rs.20,000; and (c) National Commission – above Rs. 1 crore.

Rights of the patient

1. Right to information on healthcare services available to them, diagnosis and treatment;
2. Right to have information about professionals involved in the patient care;
3. Right to safety from errors and malpractice;
4. Right to confidentiality and privacy;
5. Right to have prompt treatment in an emergency;
6. Right to get copies of medical records;
7. Right to informed consent;
8. Right to refuse to participate in human experimentation, and research;
9. Right to be informed about the rules and regulations of the hospital that apply to the patient and the facilities obtainable by the patient;
10. Right to choose and to seek second opinion about the disease and treatment etc.; and
11. Right to complain and have compensation within reasonable time.

THE ART OF INTERVIEWING (40)

Interview is a device for investigation. It is an instrument of research. The chemist carries out research in test tubes; the bacteriologist uses the microscope in his laboratory. In much the same way, the social scientist uses the interview technique in his investigations. Modern medicine has changed its character; it has emerged as a social science in recent years. Social and psychological factors have come to be recognized as dominant factors in the natural history of disease. In order to elicit these factors, it may be necessary to employ the interview technique. It may be said that the interview technique is one of the contributions of social science to modern medicine.

Aims of interview
The major aims of interview are: (1) to secure information through face-to-face association and thereby gain the portrait of the entire personality, broad enough to encompass the social and psychological background; (2) to form a hypothesis; (3) to collect personal data for quantitative purposes; and (4) to collect data from persons who are secondary sources of information.

Kinds of interview
Social scientists have described four kinds of interview: (a) Direct or structured interview: A schedule containing a set of predetermined questions is prepared. The researcher gets answers to these questions only. Generally the researcher does not add anything to what has been stated by the subject. He does not even alter the language. (b) Non-directive or Unstructured interview: No predetermined questions are asked. The researcher collects information by free discussion. The subject is asked to narrate in his own words his experiences, opinions or reactions about the particular subject under investigation. (c) Focussed interview: This type of interview is generally used to study the social and psychological effects of mass communication, e.g., reaction of a film show or radio programme. The researcher tries to focus his attention on a particular aspect of the problem and tries to know the experience, attitude and emotional responses regarding the concrete situation under study. (d) Repetitive interview: It is used when it is desired to note the gradual influence of some social or psychological process. A record has also to be maintained to study the change in continued sequence.

Technique of interview
Conducting an interview is both an art and science. Sociologists have described the following steps for conducting an interview (40).

1. ESTABLISHING CONTACT
The first requisite before conducting an interview is to establish contact with the interviewee. Prior acquaintance regarding the time and place of interview is always desirable. It gives the interviewee a sense of satisfaction and a feeling of importance that his time has been valued.

2. STARTING AN INTERVIEW
The beginning should always be made from a general discussion of the problem. The researcher should create an air of confidence and direct the interviewee in his own way. The researcher should let the interviewee do most of the talking, while he should himself listen to it attentively guiding and directing the interviewee about the subject matter wherever necessary. All controversial matters must be carefully avoided.

3. SECURING RAPPORT
A state of rapport must be established between the interviewee and the researcher. In the beginning every interviewee proceeds very cautiously giving only formal information. He may not like to discuss personal matters with a stranger. It therefore requires tact on the part of the researcher to create a friendly atmosphere and gain the confidence of the interviewee. Once rapport is gained and hesitation and shyness are overcome, the interviewee may be overzealous to tell everything that he knows, and all that he feels without any attempt at secrecy or formality. The researcher must utilize this situation to the fullest advantage, and use it as best as he can. The state of rapport sometimes may not last long; once the interviewee has relapsed into his former state, it may be very difficult to bring him back to rapport.

4. RECALL
At times, during the course of an interview, the interviewee may be so full of emotion that he drifts away from the main subject, and may even go into silence at the end of the narration. At such times, the researcher should give enough time to the interviewee to recollect and start again. At times, it may be necessary to refresh his memory by pointing out what he had been saying last.

5. PROBE QUESTIONS
When the interviewee, during an interview knowingly or unknowingly side-tracks some important aspect of the problem, the researcher has to be very cautious in catching these slips. Great care should be taken in putting probe questions. They should appear to the interviewee to be born out of mere curiosity. If the interviewee has deliberately side-tracked a particular point, a very shrewd effort is needed to make him discuss a point at length, the same should not be doggedly pursued, lest rapport should be lost.

6. ENCOURAGEMENT
During the course of an interview, it is necessary to encourage the interviewee from time to time, by interpreting such complimentary expressions as "what you have said is really very illuminating; I never had such an enlightening discussion; you really have a very unique approach to the problem; I myself had never thought of it from that angle, etc." Great care should be taken that complimentary remarks should sound true appreciations, and not flattery otherwise they will lose all their effect.

7. GUIDING THE INTERVIEW
Sometimes, the interviewee digresses in his narration to less important topics, which he is most eager to relate, and if stopped from continuing the conversation he may get offended. It is the duty of the researcher to guide the subject in the right path without offending him.
8. RECORDBING
Recording the statements should be reduced to a minimum during the course of an interview. If recording is continued, the flow of the interview will slow down and the interviewee may take the form of questions and answers. Further, the interviewee will be conscious that his statements are being recorded. The recorded interview should be set down in such an important point.

9. CLOSING THE INTERVIEW
An interview should not be ended abruptly. The interviewee should not feel at the close of the interview, that he has divulged many of his secrets to a stranger. The researcher should bring the interview to a natural close, followed by the usual forms of greetings.

10. REPORT
Soon after the interview, the report should be compiled when the mind is still fresh about the narration.

OPERATIONAL RESEARCH
The term "operational research" was coined during the World War II in connection with the best use of a new invention, the radar. Since the war, the term has spread rapidly in Britain and America and it has come to mean today more than the study of the use of new inventions—the study of the whole system of services rendered in industry, administration, education and health services (38).

Operational research is defined as the application of scientific methods of investigation to the study of complex human organizations and services. A mathematician working on atomic structure is pursuing pure research; an engineer designing a new plant for an industry is pursuing applied research. In operational research, one is concerned all the time with the activities of a group of people with the purpose of inducing beneficial changes. Thus, operational research is a sociological science, and has an immense social content which distinguishes it from pure or applied research. The main objective of operational research is "to develop new knowledge about institutions, programmes, use of facilities, the people working in these activities and the individuals and communities served by them." In order to secure optimal utilization of resources in men, material and money in the service of the community (41). A new area of operational research is emerging, i.e. "health operational research" (42).

Phases in operational research
The procedure to be adopted in operational research differs according to the nature of the study. The usual procedure adopted generally consists of the following phases:

1. Formulation of the problem.
2. Collection of relevant data, if necessary, by a suitable sample.
3. Analysis of data and formulation of hypothesis.
4. Deriving solutions from the hypothesis or "model."
5. Choosing the optimal solution and forecasting results.
6. Testing of solution, e.g., pilot projects.
7. Implementing the solution in the whole system.

Operational research team
Operational research is a team work job and involves several workers. The composition of the team varies with the type of research. The minimum composition in social medicine applications is probably a public health administrator, an epidemiologist, a statistician, and a social scientist. This is in addition to ancillary workers such as clerks, peren and field workers. The team is headed by a director who is responsible for the whole project.

Operational research in health services (42)
Practically everything within the broad field of public health and social medicine—either a whole system or part of it—could be the subject of operational research. Examples of such problems are: optimal size of area and population to be served by a midwife, or basic health unit; ideal vehicle for local health workers; leaving maximum time for technical personnel to utilize their skills; architectural design of hospitals and health centres; queuing problems in outpatient departments and hospital waiting lists; solutions to integration problems where specialised services have developed on emergency basis outside the general health services; study of bed load and nursing services in teaching and non-teaching hospitals; length of stay in hospitals and length of sickness absence; effectiveness or the extent to which the stated objective of a programme, e.g., malaria eradication, family planning is achieved; quality of medical care services; investigation of outbreaks of epidemic diseases and many others. Wherever social medicine passes from the stage of observation and classification to that of discovering and recommending appropriate action, it is involved in operational research.

SOCIAL PROBLEMS
In a community, there are both individual and social problems. When individual problems affect a large number of people, they become social problems. Some of the present day social problems are alcoholism, drug dependence, STD, vagrancy, juvenile delinquency, prostitution etc. Some of the social problems have medical implication, e.g., venereal diseases. Social problems are solved by social and political action, that is by social welfare programmes, social assistance, social legislation in the community to curb the social evils (e.g., The Prevention of Food Adulteration Act; The Prevention of Immoral Traffic Act; The Medical Termination of Pregnancy Act).

Prostitution
Prostitution is an age-old social evil. It is a social problem in most urban areas, and to a lesser extent in rural areas. Sociologists who have studied prostitution have mentioned the following underlying causes of prostitution: (1) changes in environment (2) breakdown of family relations (3) parental quarters (4) want of affection (5) illegitimate love (6) easy money (7) low I.Q. (8) low moral standards (9) poverty, etc. The Government of India passed an Act in 1956 known as "The Suppression of Immoral Traffic Act in women and girls" which bans prostitution in its commercialized form as an organized means of living. The Act was amended and restated as "Immoral Traffic (Prevention) Act" in 1986. It covers all persons, whether male or female, who are exploited sexually for commercial purposes.

Delinquency
A delinquent is one who shows deviation from normal behaviour. In other words, he is one who has committed an offence, e.g., theft, sexual offence, murder, burglary, etc. Delinquency is a social problem in many communities. The causes responsible for delinquency are social maladjustment, poverty, disturbed home conditions, alcoholism, drug addiction, and modern ways of living.
The programmes for the prevention and control of juvenile delinquency centre round the implementation of The Children Act, 1960 which provides a specialized approach towards the care, protection, maintenance, training and rehabilitation of delinquent children. The institutional infrastructure consists of Juvenile/Children’s Courts, child welfare boards, reed and homes, certified schools, children homes and after-care facilities.

**Dowry system**

Dowry started as an innocent custom, a symbol of love from parents to their daughter on the eve of her marriage. But it has, in recent years, grown into a social evil with many instances of bride-burning and suicides. These are symptoms of societal corruption.

Under the Dowry Prohibition (Amendment) Act, 1986 the minimum punishment for taking or abetting the taking of dowry has been raised to 5 years’ imprisonment and a fine of Rs.15,000. What is required is a sustained effort to go into the root causes of these evils. Well-intentioned social customs cannot be easily erased by an Act of Parliament.

**Drug addiction**

Drug addiction is defined as a state of periodic or chronic intoxication detrimental to the individual and society produced by the repeated intake of habit-forming drugs.

Drug abuse has reached an alarming proportion in recent years. “Drug culture” is fast making inroads into the lives of young people from all walks of life. The reasons given for drug dependency include the following:

- Curiosity and natural tendency to experiment with drugs
- Disturbed home environment: children from broken homes, indifferent parents, lack of communication between parents and children
- An escape phenomenon from tensions and frustrations in life, e.g., unemployment, failire in examinations
- Impact of disco culture, mobile, TV, internet etc.
- Ignorance regarding the habit-forming nature of the drugs.

To call a person a drug addict, the following criteria must be satisfied:

1. **Psychological dependence**: there is an overpowering desire (compulsion) to take the drug and obtain it by any means.

2. **Physical dependence**: when the drug is withdrawn, the patient shows “withdrawal symptoms” such as irrational and violent behaviour, nausea, diarrhoea, watering of eyes and nose, etc.

3. **Development of tolerance**: there is a tendency to increase the dose.

**Management**

Though drug addiction may be considered as a social problem, the first step in its management is medical care, which includes:

a. Identification of drug addicts and their motivation for drug detoxification
b. Detoxification (requires hospitalization)

c. Post-detoxification counselling and follow-up (based on clinic and home visits), and

d. Rehabilitation.

Simultaneously with medical treatment, changes in environment (home, school, college, social circle) are important. The patient must effect a complete break with his group, otherwise the chances of relapse are 100 per cent. Psychotherapy has a valuable place in the management of the addict.

Preventive measures include education of target groups and the general public through TV, radio, leaflets, and posters to create awareness of the problem. The Government has promulgated an Act called the “Narcotic Drugs and Psychotropic Substances Act” which came into force in 1985 to combat this problem. Refer to Chapter 17 for further details.

**Alcohol abuse**

Alcoholism is world-wide social and medical problem. Over the past 30 to 40 years, alcohol consumption has increased in quantity and frequency. The number of people who start drinking has also declined. The population groups at greatest risk are those undergoing rapid socio-economic and cultural changes; they view alcohol as a symbol of prestige and social status.

Consequences: The consequences of alcohol abuse cover a wide spectrum: crime, murder, prostitution, neglect of families, malnutrition, disease (e.g., cirrhosis of liver, alcohol-dependent syndrome, alcoholic psychosis), unemployment, indebtedness, child delinquency, road accidents, loss of friends and self-esteem. In short excessive alcohol results in serious medical, psychological and sociological problems.

Drinking by adults serves as a role model for the young. The identification of risk factors is essential for prevention. As drinking patterns vary considerably, the prevention of alcoholism is not easy. A widespread public education and discussion, and investigation of public attitudes may result in measurable improvement. This should be combined with social welfare and health services. Refer to Chapter 17 for further details.

**Unmarried mothers**

We do not have accurate statistics regarding unmarried mothers in India. Because of social customs and traditions in India, the problem of unmarried mothers in India must be significant. Such mothers have a multiplicity of needs — not only for medical termination of pregnancy and health care, but also for understanding, warmth and guidance. In Western societies, where this problem is acute, they have special schools and counselling programmes for teenage mothers.

**Handicapped**

The handicapped comprise 7 main categories as shown below, during 2/11 (43).

<table>
<thead>
<tr>
<th>Categories</th>
<th>Estimated number in India</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i) The blind</td>
<td>5.03 million</td>
</tr>
<tr>
<td>(ii) The hearing disabled</td>
<td>5.97 million</td>
</tr>
<tr>
<td>(iii) The orthopodically handicapped</td>
<td>5.43 million</td>
</tr>
<tr>
<td>(iv) Multiple disabilities</td>
<td>2.11 million</td>
</tr>
<tr>
<td>(v) The mentally retarded</td>
<td>1.50 million</td>
</tr>
<tr>
<td>(vi) The mental illness</td>
<td>0.72 millions</td>
</tr>
<tr>
<td>(vii) Speech disability</td>
<td>1.99 million</td>
</tr>
<tr>
<td>(viii) Others</td>
<td>4.92 million</td>
</tr>
</tbody>
</table>
The above figures are not static but ever growing. In all civilized countries, the State looks after the handicapped. The rehabilitation services available for the handicapped in India are as follows: (1) medical care facilities, (2) education for the blind, deaf and the orthopaedically handicapped, (3) vocational training, (4) job placement and sheltered workshops, (5) pensions, scholarships and allowances for the education and training of the handicapped.

SOCIAL AGENCIES

Social welfare services have always been an integral part of the socio-cultural tradition of India. Soon after Independence, on the basis of a survey made by the Planning Commission, it was estimated that there were 10,000 voluntary organizations in the field of social welfare. Today the number is much greater. The activities are coordinated and assisted by the Ministry of Social Welfare and Women's Affairs. An autonomous Central Social Welfare Board is the main agency of the Ministry for undertaking and implementing programmes for women through the voluntary sector. Activities include welfare, training, health care, provision of women's hostels, as well as legal aid and support to women being exploited by families or employers. A few of the principal agencies are listed below:

1. All India Women's Conference, 6 Bhagwandas Road, New Delhi-110 001
2. National Association of Rural Women, Room No. 9104, Jamnagar Hutments Block 11, Mansabgh Road, New Delhi-110 001
3. National Council of Women, 12 Circular Road, Parno-800 001
4. India Social Institute, Department of Women's Development, 24 Benson Road, Bangalore-560046
5. Centre of Science for Villages, Magan, Sangrahayu, Wardha – 442 001

COMMUNITY SERVICES

Administrative pattern of the country

(1) CENTRE

India is a Union of 29 States and 7 Union territories. Last state Telangana was formed on 2nd June 2014. The Constitution of India came into force on 26 January, 1950. The Union Executive consists of the President, the Vice-President, the Prime Minister and the Council of Ministers. Rules of business have been framed under the Constitution.

India is a sovereign Democratic Republic with a Parliamentary form of government. Sovereignty ultimately rests with the people. The Parliament consists of the President, and the two Houses of Parliament – The Rajya Sabha and the Lok Sabha. The Rajya Sabha consists of 250 indirectly elected members, and the Lok Sabha 544 directly elected members. The main functions of Parliament are to make laws for the country, and to make finances available to the Government. The Parliament is assisted by several committees. The term of the Lok Sabha is 5 years.

(2) STATE

The administrative pattern in the States closely resembles that of the Union. The States executive consists of a Governor, and a council of Ministers with a Chief Minister as its head. The Governor who is the head in each state is appointed by the President for a term of 5 years. The State Legislature consists of Vidhan Sabha (Legislative Assembly) and its members are chosen by direct election. In Some States, there is also an Upper House known as Vidhan Parishad or Legislative Council. The powers of the State Legislature have been defined in the Constitution.

The Union territories (e.g. Puducherry, Andaman and Nicobar are administered by the President through an Administrator).

(3) LOCAL GOVERNMENT

(a) Urban areas: In big cities, the local Government institution is known as Corporation, and in medium and small towns as Municipal Committee or Council. The Corporations are headed by elected Mayors. The executive power of the Corporation vests in the Commissioner. The Corporation deals with matters concerning public health and sanitation, maintenance of roads, bridges, markets, playgrounds, parks and education. Municipalities are headed by elected Presidents.

(b) Rural areas: The rural areas are governed by the system of Panchayat Raj or democratic decentralization.

Democratic decentralization

In democratic societies, the trend is to distribute power as much as possible to the people themselves so that they may be able to manage their own affairs. The Panchayat Raj in India is nothing but democratic decentralization. It is a 4-tier system of local self-government.

Village level .... Gram Panchayat
Block level .... Panchayat Samiti
District level .... Zilla Parishad

Gram Panchayats are elected by Gram Sabhas consisting of the entire adult population of the village. The panchayat consists of 9 to 15 elected members. The Panchayats are responsible for agricultural production, rural industries, medical relief, mother and child health, maintenance of village roads and streets, tank and sanitation. It is envisaged that the Panchayat institutions will control everything including primary health centres and local schools. The Panchayat Samiti or Janpad Panchayat federates at the Block level, and the Zilla Parishad at the District level. The Panchayat Raj institutions have their own powers of taxation. For the speedy disposal of Justice, Nyaya (Judicial) Panchayats or village courts have also been established.

LAWS

Laws are rules of the State. They regulate the individual and community behaviour. Some laws come into existence out of the local customs and traditions, e.g., the Hindu marriage Act. There are laws which are enacted by Parliament and State Legislatures. The supreme law of the land is the Constitution which sets out the rights of Government and an individual. Some of the important laws in the field of community health in India are:

(1) The Prevention of Food Adulteration Act, 1954
(3) The Employees' State Insurance Act, 1948.
(7) The Central Birth and Death Registration Act, 1909.
(8) The Epidemic Diseases Act, 1897.

COOPERATIVES

Cooperatives are a form of conducting business in society. Profits are distributed after all the costs are paid. The Government has established a system of cooperative societies for helping the farmers to obtain loans for dairy, poultry, and irrigation purposes. There are also other cooperatives such as Consumer Societies in urban and rural areas. There are also District Cooperative Unions and State Cooperative Unions.

EDUCATIONAL SERVICES

Education is one of the fundamental rights of man. The purpose of education is to "socialize" children so that they may imbibe the social values and norms of society and to prepare them as useful citizens. Education in India is primarily a responsibility of the State. The Constitution provides for free and compulsory education up to the age of 14 years. The National Policy on Education aims at achieving this goal, and for an investment of 6 per cent of National Income on education. The literacy rate in India for the year 2011 was 74.04 per cent; male literacy rate 82.14 per cent; female literacy rate 65.46 per cent. Education is fundamental to health and health to education.

The Central Government is concerned with the determination of educational standards, scientific and technical education, and research. The Medical Council of India prescribes standards for medical education in the country. There is a Ministry of Education at the Central and State levels. Education is thus an important community service, and the school an important community institution.

RECREATION AND CULTURAL ACTIVITIES

India has a great cultural heritage of dance, drama, music, and art. There are 3 National Academies for the promotion of art, music and dance. Besides these, there are State Academies for the promotion of art. The All India Radio with its network of stations and the Television are powerful mass media in the country. India also leads the world in the production of films. The documentary films depict the life, art and culture of people in different regions of the country.

ECONOMICS

The word "economics" literally means "house-keeping". It deals with the human relationships in the specific context of production, distribution, consumption, ownership of resources, goods and services. Economics and sociology overlap in many areas.

Natural resources of the country

India is rich in natural resources and man-power

(1) Agriculture: Agriculture is the main plank of the Indian economy. It accounts for nearly 44 per cent of the National Income, and provides employment to nearly 70 per cent of India's population. (2) Forestry: Forests constitute another important basic natural resource of the country. Nearly 19.4 per cent of the total land area of the country is occupied by forests. Forests are a source of timber, bamboo, canes, tendu leaves, gum, resins, tanning materials, rubber, dyes, tannery, etc. (3) Fisheries: India has a vast sea-coast. The marine products earn foreign exchange. (4) Minerals: India is richly endowed with minerals, e.g., bauxite, coal, copper, diamond, gold, iron ore, manganese, mica, nickel, etc. (5) Man-power: The greatest natural resource of the country is its man-power. The population of the country is 1,270 million (2011). The people of India account for about 16 per cent of the world's population, while occupying only 2.4 per cent of the world's land area.

OCCUPATIONS

One of the first questions we ask a stranger or new acquaintance is "What are you doing?" or "What is your job?". Occupation is thus a basis of social differentiation. Some occupations are prestigious (e.g., doctors, judges); others (e.g., manual labour) are not. Occupation also reflects the income of the individual, and his standard of living. The occupational structure in India is as shown in Table 5.

INDUSTRIALIZATION

During the early years of this century, the major industries in India were cotton mill industry, jute industry and coal mining. During recent years, there has been considerable industrial expansion. A number of new industries have come up such as steel, sugar, cement, glass, chemicals, soap, vanaspati, heavy electrical and machine tools, etc.

Industries create new conditions of life and new conditions for adaptation. There is shifting of the population from rural to urban areas. People are removed from the warm intimacy of village life to the isolated and impersonal life in towns and cities. The community health problems arising out of industrialization are water and air pollution, creation of slums, accidents, communicable disease problems such as tuberculosis and venereal diseases; mental health problems such as delinquency, psychosis and social problems such as alcoholism, drug dependence, prostitution, gambling and crime.

Health problems in industrialized countries have passed through various evolutionary stages, each characterized by different challenges to public health and personal health care. In the initial stage, infectious diseases, malnutrition,
and poor housing were combated by socio-economic improvements in combination with public health measures such as the provision of pure water supply and sewage disposal facilities. As scientific advances were made, broader control of acute bacterial and viral diseases were achieved by means of immunization and chemotherapy as well as increased health care for individuals.

The second evolutionary stage has been dominated by chronic diseases, particularly cardiovascular and cerebrovascular diseases and cancer. Scientific and technological progress has produced a wide array of medical interventions for diagnosis and cure, higher levels of specialization in medical practice, and transfer of much of the care previously rendered in doctor’s clinics to elaborate and expensive hospitals. The cost of health care has risen dramatically.

There is evidence in some industrialized countries of a third stage, which might be described as social and environmental pathology. Threats to health wise not from intrinsic disorders of bodily structure and function, but from environmental hazards related to urban development and exposure to toxic substances, as well as from changes in social behaviour associated with violence, alcohol, and drug abuse of epidemic proportion. Industrialized countries have passed through these three stages over the course of more than a century. Developing countries, on the other hand, face the challenge of coping with all the three stages simultaneously, with just a fraction of the human and material resources available to their industrialized counterparts. Policies must be closely related to overall socio-economic development if countries with limited resources are to achieve the greatest possible benefits in health (46).

**ECONOMIC LEVELS**

**National Income**

An important background influence is the size and strength of the domestic market, which is usually expressed in terms of one of the national aggregates, such as gross national product (GNP) or gross domestic product (GDP). These measures indicate the level of economic activity at current or constant price. By dividing the GNP or GDP by the total population, one arrives at per capita GNP or GDP, which are common general purpose indicators of national wealth. Per capita GNP may thus serve as a general measure of human welfare—that is, of health in a very broad sense. In practice, many health variables are indeed correlated with per capita GNP or GDP. Countries with a high per capita GNP are predominantly industrially developed, while those with a low one are predominantly agricultural, or developing.

**Gross National Income (GNI)**

Formerly known as GNP or Gross National Product. It is gross income generated from within the country as also net income received from abroad. It is expressed either at constant prices or at current prices during the period to which the figure refers, or at constant prices: i.e. at prices prevailing during a fixed base period in the past, irrespective of the period to which the figures refer. Thus figures at current prices discount the effect of inflation after the base period and measure the changes in real terms. Figures at current prices are naturally influenced by inflation but are more useful for, say, international comparisons for the same period.

For GNI per capita US $, the national currency is converted to current US Dollars using the World Bank Atlas Method. This involves using a 3 year average of exchange rates (45).

**PER CAPITA INCOME**

An index of the standard of living of the people is “per capita income”. Per capita income in India is among the lowest in the world. According to recent statistics, the per capita income in India (2012–13) was Rs. 68,784 at current prices.

**Gross Domestic Product (GDP)**

GDP is gross income generated within a country, i.e., it excludes net income received from abroad.

**Net National Product (NNP)**

It is the GNP minus the capital we consume (e.g., equipment, machinery, etc.) in the production process. In other words, NNP is the market value of all final goods and services after providing for depreciation.

**Net Domestic Product (NDP)**

It is the gross domestic product minus the value of depreciation on fixed assets.

**GDP at Market Price**

It is GDP at factor cost plus indirect taxes minus subsidies.

**NNP at Market Price**

It is NNP at factor cost plus indirect taxes minus subsidies.

**GDP at Factor Cost**

It is GDP at factor cost plus indirect taxes minus subsidies.

**Purchasing Power Parity (PPP)**

It is defined as the number of units of a country’s currency required to buy the same amount of goods and services in the domestic market as one dollar would buy in the USA. According to the latest calculation of per capita GNI and gross GNP of the World Bank, based on PPP, India’s per capita GDP in 2011 has been estimated at $ 3560 (PPP), it is the fourth largest country in terms of GNP (PPP) with about $ 2.5 trillion, preceded by the USA ($ 5.98 trn.), China (about $ 5.4 trn.) and Japan ($ 3.3 trn.) (44).

**Gross Domestic Savings**

It is excess of current income over current expenditure.

**Poverty**

The number of people living in extreme poverty in the world has increased, and was estimated that about 19 per cent of world’s population was living below one dollar per day income during the year 2005 (47). Poverty yields its destructive influence at every stage of human life from the moment of conception to the grave. Poverty is the main reason why babies are not vaccinated, clean water and sanitation are not provided, and curative drugs and other treatments are unavailable. It is the main cause of low life expectancy, low birth weight babies, higher maternal mortality, handicapped and disability, mental illness, stress, suicide family disintegration and substance abuse. Table 6 shows the influence of income on health in South-East Asia Region.

The health consequences of poverty are severe. The poor die younger and suffer more from disability. They are exposed to greater risk from unhealthy conditions at home and at work. Malnutrition and the legacy of past illness mean that they are more likely to fall ill and slower to recover, especially if they have little access to health care. When a family's breadwinner becomes ill, other members of the household may at first cope by working harder themselves and by reducing consumption, even of food. Both adjustments can harm health of the whole family (48).

The poor are forced into occupations that harm their health, lack of access to health care and education, live shorter life and in general lack access to resources and means to improve their lives. These social and economic aspects of poverty are inextricably linked. Addressing these underlying social factors can enable people to escape poverty. Sound economic policies must go hand-in-hand with addressing the social needs of the poor.

Investments to reduce health risks among poor and provision of insurance against catastrophic health care costs are important elements in a strategy for reducing poverty.

Global Hunger Index (GHI) (50)

The Global Hunger Index (GHI) is a tool designed to comprehensively measure and track hunger globally, by region and country. It highlights successes and failures in hunger reduction. It is calculated each year by the International Food Policy Research Institute.

GHI combines three equally weighted indicators into one index:
1. Undernourishment : the proportion of undernourished people as a percentage of the population (reflecting the share of the population with insufficient calorie intake);
2. Child underweight : the proportion of children under the age of five who are underweight (that is, have low weight for their age, reflecting wasting, stunted growth, or both), which is one indicator of child undernutrition; and
3. Child mortality : the mortality rate of children under the age of five (partially reflecting the fatal synergy of inadequate food intake and unhealthy environments).

The global hunger index is calculated by the following formula:

\[
\text{GHI} = \frac{\text{Proportion of undernourished population (PNU)} + \text{Children under weight (CUW)} + \text{Child mortality in per centage (CM)}}{3}
\]

For India the GHI for the year 2014 is:

\[
\frac{17.0 + 30.7 + 5.6}{3} = 17.8
\]

The calculations result in a 100-point scale on which zero is the best score (no hunger) and 100 the worst, although neither of these extremes is reached in practice. A value of 100 would be reached only if the whole population was undernourished, all children younger than five were underweight, and all children died before their fifth birthday. A value of zero would mean that a country had no undernourished people in the population, no children younger than five who were underweight, and no children who died before their fifth birthday.

Some definitions
1. Hunger: distress related to lack of food.
2. Malnutrition: an abnormal physiological condition, typically due to eating the wrong amount and/or kinds of foods; encompasses undernutrition and overnutrition.
3. Undernutrition: deficiencies in energy, protein, and/or micronutrients.
4. Micronutrient deficiency (also known as hidden hunger): a form of undernutrition that occurs when intake or absorption of vitamins and minerals is too low to sustain good health and development in children and normal physical and mental function in adults. Causes include poor diet, disease, or increased micronutrient needs not met during pregnancy and lactation.
5. Undernourishment: chronic calorie deficiency, with consumption of less than 1,800 kilocalories a day, the minimum most people need to live a healthy, productive life.
6. Overnutrition: excess intake of energy or micronutrients.

Hidden hunger
Hidden hunger (micronutrient deficiency) is a form of undernutrition that occurs when intake and absorption of vitamins and minerals (such as zinc, iodine, and iron) are too low to sustain good health and development. Factors that contribute to micronutrient deficiencies include poor diet, increased micronutrient needs during certain life stages, such as pregnancy and lactation, and health problems such as diseases, infections, or parasites.

While clinical signs of hidden hunger, such as night blindness due to vitamin A deficiency and goitre from inadequate iodine intake, become visible once deficiencies become severe, the health and development of a much larger share of the population is affected by less obvious "invisible" effects. That is why micronutrient deficiencies are often referred to as hidden hunger.

Hidden hunger afflicts more than 2 billion individuals, or one in three people, globally (FAO, 2013). Its effects can be devastating, leading to mental impairment, poor health, low productivity, and even death. In adverse effects on child health and survival are particularly acute, especially within the first 1,000 days of a child's life, from conception to the age of two, resulting in serious physical and cognitive consequences. Even mild to moderate deficiencies can affect a person's well-being and development. In addition to
affecting human health, hidden hunger can curtail socio-economic development, particularly in low and middle income countries.

The nature of the malnutrition burden facing the world is increasingly complex. Developing countries are moving from traditional diets based on minimally processed foods to highly processed, energy-dense, micronutrient-poor foods and drinks, which lead to obesity and diet-related chronic diseases. With this nutrition transition, many developing countries face a phenomenon known as the “triple burden” of malnutrition-undernutrition, micronutrient deficiencies, and obesity. In higher income, more urbanized countries, hidden hunger can co-exist with overweight/obesity when a person consumes too much dietary energy from macronutrients such as fats and carbohydrates. While it may seem paradoxical, an obese child can suffer from hidden hunger.

The consequences of hidden hunger on the different stages of lifecycle are shown in Fig. 2.

**Reproductive health and poverty reduction**

Reproductive health has a significant role in poverty reduction and it is expected that successful programmes to promote reproductive health will contribute to the reduction of healthy year of life lost and hence the poverty reduction in equal measure. In addition to reduction of mortality and morbidity, reproductive health programmes address to unmet needs for family planning, relieving the poor of the burden of unwanted pregnancies and large families; they provide much-needed information and services to promote sexual health and responsible behaviour among adolescents and young people; and they promote gender equality and women’s empowerment which is necessary for the success of reproductive health interventions. In doing so, these programmes contribute directly to the Millennium Development Goals of United Nations (49). Fig. 3 shows how reproductive health can be used as a tool to poverty reduction.

Poverty is the most obvious problem in India. According to 2011–12 estimate about 21.9 per cent (269.78 million) population of the country is living below the “poverty line”. The “poverty line” is defined as expenditure required for a daily Calorie intake of 2,400 per person in rural areas and 2,100 in urban areas. This expenditure is officially estimated at Rs. 228.9 per capita per month in rural areas and Rs. 264.1 in urban areas at 1993–94 prices (44).

**STANDARD OF LIVING**

Please see page 672 for details.

**SOCIAL SECURITY**

Social security is defined as “security that society furnishes through appropriate organization against certain risks to which its members are exposed”. The risks which social security covers in most countries are sickness, invalidity, maternity, old age and death. Social security also includes social insurance and social assistance.

**Social security for Industrial workers**

The social security measures for industrial workers in India are contained in the following legislations:

1. Workmen’s Compensation Act, 1923
2. Central Maternity Benefit Act, 1961
3. Employees State Insurance Act, 1948
4. The Family Pension Scheme, 1971

![Fig. 2](source.png)

Consequences of micronutrient deficiencies throughout the lifecycle

Source: (50)
Some of these Acts have been described elsewhere in the text.

**Social security for civil servants**

The employees of the Central and State Government have pension, gratuity, provident fund and family pension schemes. The Central Government Health Scheme in Delhi provides comprehensive medical care to all categories of Central Government Employees. The scheme has been extended to other cities also.

**Social security for general public**

The risks of death, accident, and fire etc. are covered by the Insurance schemes. The Life Insurance Corporation of India has many schemes for the general public. There are also public provident fund and ESI schemes.

The term environment implies all the external factors—living and non-living, material and non-material—which surround man. In its modern concept, environment includes not only the water, air and soil that form our environment but also the social and economic conditions under which we live.

For descriptive purpose, environment has been divided into three components, all closely related:

(i) Physical: Water, air, soil, housing, wastes, radiation, etc.
(ii) Biologic: Plant and animal life including bacteria, viruses, insects, rodents and animals.
(iii) Social: Custom, culture, habits, income, occupation, religion etc.

The key to man’s health is largely in his environment. In fact, much of man’s ill-health can be traced to adverse environmental factors such as water pollution, solid pollution, air pollution, poor housing conditions, presence of animal reservoirs and insect vectors of diseases which pose a constant threat to man’s health. Often man is responsible for the pollution of his environment through urbanisation, industrialisation and other human activities. In 1972 the UN conference on the Human Environment focussed worldwide attention on the environmental hazards that threaten human beings. To facilitate work in this area, WHO has compiled a wide-ranging survey of environmental hazards to human health.

The dictionary meaning of the word sanitation is “the science of safe-guarding health.” One of the best definitions is that given by the National Sanitation Foundation of the USA, which is as follows: “Sanitation is a way of life. It is the quality of living that is expressed in the clean home, the clean farm, the clean business, the clean neighbourhood and the clean community. Being a way of life it must come from within the people; it is nourished by knowledge and grows as an obligation and an ideal in human relations.” The term “environmental sanitation” has been defined by WHO as “the control of all those factors in man’s physical environment which, exercise or may exercise a deleterious effect on his physical development, health and survival.”

In the past, sanitation was centred on the sanitary disposal of human excreta. Even now, to many people sanitation still means the construction of latrines. In actual fact, the term sanitation covers the whole field of controlling the environment with a view to prevent disease and promote health. Man has already controlled a number of factors in his environment, e.g., food, water, housing, clothing, sanitation. These controllable factors are those included in the “standard of living”. It is the control of these factors that has been responsible for considerable improvement in the health of the people during the past century in the developed countries. However, man’s mastery over his environment is not complete. As old problems are being solved, new problems are arising. Air pollution is of growing concern in many urban centres. Industrial growth has given rise to the problem of environmental pollution by industrial wastes. Advances in nuclear technology have produced the problem of radio-active pollution of the environment. The demographic growth and fast urbanisation all over the world are bringing profound social and environmental changes. Therefore, the attainment of a healthy environment is becoming more and more complex. The term environmental sanitation is now being replaced by environmental health. Proper environmental health now requires the services of the public health qualified doctor, the epidemiologist, the public health engineer, the town planner, the sociologist, the economist, and the health inspector. A purely medical or engineering approach by itself is no longer sufficient; a combined multi-disciplinary programme of action is needed to achieve a healthy environment.

The purpose of environmental health is to create and maintain ecological conditions that will promote health and thus prevent disease. One of the essential public health care element is safe drinking water and sanitation. In 1990, more than 1 billion people in developing world lacked access to safe drinking water and nearly 2 billion people lacked an adequate system for disposing off their excreta. Faeces deposited near homes, contaminated drinking water (sometimes caused by poorly designed or maintained sewage systems), fish from polluted rivers and coastal waters, and agricultural produce, fertilized with human waste are all health hazards. Water quantity is as important as water quality. Washing hands after defecation and before preparing food is of particular importance in reducing disease transmission, but without abundant water in or near home, hygiene becomes difficult or impossible. The lack of water supply and sanitation is the primary reason why diseases transmitted via faeces are so common in developing countries. The most important of these diseases, diarrhoea and intestinal worm infestations, account for 10 per cent of the total burden of disease in developing countries. In addition, an inadequate water supply increases the risk of schistosomiasis, skin and eye infections, and guemaworm disease. Table 1 shows the percentage of population with access to safe water and adequate sanitation in South-East Asia countries.

Two of the changes needed to achieve “Health for All” are concerned with a healthy environment and healthy lifestyle and require initiatives by the individual, the family...

Source: (18)

and the community, “Africa 2000” a new initiative aimed at providing universal coverage of water supply and sanitation services was launched. A broad programme for hygiene education and promotion of low-cost sanitation is being developed in cooperation with UNICEF and bilateral and multilateral organizations. Key hygiene behaviours and principles for promoting sanitation were identified. The global WHO/UNEP network for air and water quality monitoring are operational in more than 60 countries. Surface and ground water quality are monitored in 350 cities worldwide (2).

Much of the ill-health in India is due to poor environmental sanitation, that is, unsafe water, polluted soil, unhygienic disposal of human wastes and refuse, poor housing, insects and rodents. Air pollution is also a growing concern in many cities. The high death rate, infant mortality rate, sickness rate and poor standards of health are in fact largely due to defective environmental sanitation. Improvement of environmental sanitation is therefore crucial for the prevention of disease and promotion of health of individuals and communities. Since more than 70 per cent of the population of India live in rural areas, the problem is one of rural sanitation. The first step in any health programme is the elimination through environmental control of those factors which are harmful to health. The environmental factors which are basic and fundamental to individual and community health are discussed in this chapter.

Much of the ill-health which affects humanity, especially in the developing countries can be traced to lack of safe and wholesome water supply. Water that is easily accessible, adequate in quantity, free from contamination, safe and readily available throughout the year. There can be no state of positive health and well-being without safe water. Water is not only a vital environmental factor to all forms of life, but it has also a great role to play in socio-economic development of human population. Each country should develop its own water resources agency which would collect all pertinent data on water resources, exploitation and hydrogeology. In 1981, the 34th World Health Assembly in a resolution emphasized that safe drinking water is a basic element of “primary health care” which is the key to the attainment of “Health for All by the year 2000 AD”. More recently, Millennium Development Goals included safe water and sanitation in the attainable goals. Water is integrated with other PHC components because it is an essential part of health education, food and nutrition, and also MCH.

Safe and wholesome water
Water intended for human consumption should be both safe and wholesome. This has been defined as water that is:

- free from pathogenic agents;
- free from harmful chemical substances;
- pleasant to the taste, i.e., free from colour and odour; and
- usable for domestic purposes.

Water is said to be polluted or contaminated when it does not fulfil the above criteria. Water pollution is a growing hazard in many developing countries owing to human activity. Without ample and safe drinking water, we cannot provide health care to the community.

Water requirement
The basic physiological requirements for drinking water have been estimated at about 2 litres per head per day. This is just for survival. But from the standpoint of public health and improvement of the quality of life, water should be provided in adequate volume. It will help to reduce the incidence of many water-related diseases among the people most at risk. The consumption of water, however, depends upon climate conditions, standard of living and habits of the people. A daily supply of 150–200 litres per capita is considered as an adequate supply to meet the needs for all urban domestic purposes. In India 40 litres of water supply per capita per day was the target to be achieved in rural areas. It must be available close to the people, else they have to spend hours and a lot of energy, going back and forth to obtain it and the water is often polluted in the process.

Uses of water
The uses of water in a community are many, and the requirement in quantity and quality are varied. Conventionally, it has been convenient and economical to provide a single water supply sufficient in quantity to serve all uses and suitable in quality to meet drinking requirements, even though only a small fraction of the total water supply is actually used for drinking.

The uses of water include:

1. Domestic use: on domestic front, water is required for drinking, cooking, washing and bathing, flushing of toilets, gardening etc.

2. Public purposes: cleaning streets, recreational purposes like swimming pools, public fountains and ornamental ponds, fire protection and public parks.

3. Industrial purposes: for processing and cooling.

5. Power production from hydropower and steam power.

6. Carrying away waste from all manner of establishments and institutions.

Water is therefore an essential factor in the economic, social and cultural development of a community. It can eliminate diseases, promote rural development and improve quality of life.

Sources of water supply
Water may be abstracted for use from any one of a number of points in its movement through the hydrological cycle. The safe yield of the source must be sufficient to serve the population expected at the end of the design period, which may be 10 to 50 years in future. The safe yield is generally defined as the yield that is adequate for 95 per cent of the year. The selection of a source requires professional advice. In general, water sources must conform to two criteria: (a) the quantity must be sufficient to meet present and future requirement (b) the quality of water must
be acceptable. There are three main sources of water:

1. RAIN
2. SURFACE WATER
   Impounding reservoirs
   Rivers and streams
   Tanks, ponds and lakes.
3. GROUND WATER
   Shallow wells
   Deep wells
   Springs.

1. Rain
Rain is the prime source of all water. A part of the rain water sinks into the ground to form ground water; part of it evaporates back into the atmosphere, and some runs off to form streams and rivers which flow ultimately into the sea. Some of the water in the soil is taken up by the plants and is evaporated in turn by the leaves. These events are spoken of as "water cycle". CHARACTERISTICS: Rain water is the purest water in nature. Physically, it is clear, bright and sparkling. Chemically, it is very soft water containing only traces of dissolved solids (0.005% per cent). Being soft, it has a corrosive action on lead pipes. Bacteriologically, rain water from clean districts is free from pathogenic agents.

IMPURITIES: Rain water tends to become impure as it passes through the atmosphere. It picks up suspended impurities from the atmosphere such as dust, soot and microorganisms and gases such as carbon dioxide, nitrogen, oxygen and ammonia. Gaseous sulphur and nitrogen oxides are emitted from power plants that use fossil fuels. These gases react with atmospheric water, forming dilute solution of sulphuric and nitric acid. The precipitation of these acids (acid rain) has begun to have serious impacts on surface water quality and on plants etc. There are very few places in the world like Gibraltar which depend upon rain as a source of water supply.

2. Surface water
Surface water originates from rain water. It is the main source of water supply in many areas. Examples of surface water include rivers, tanks, lakes, wells (water source which are dry, except in rainy season), man-made reservoirs and sea water. Surface water is prone to contamination from human and animal sources. As such it is never safe for human consumption unless subjected to sanitary purification and purification before use.

The vast majority of Indian cities and towns depend upon surface water sources, which are (1) Impounding Reservoirs, (2) Rivers and Streams, and (3) Tanks. Ponds and lakes in general, surface water supplies possess a high probability of organic, bacterial and viral contamination.

(1) IMPOUNDING RESERVOIRS
These are artificial lakes constructed usually of earthwork or masonry in which large quantities of surface water is stored. Dams built across rivers and mountain streams also provide large reserves of surface water. The area draining into the reservoir is called "Catchment area". Cities such as Mumbai, Chennai and Nagpur derive their water supply from impounding reservoirs. One disadvantage of storing water for long periods in reservoirs is the growth of algae and other microscopic organisms, which impart bad tastes and odours to water. CHARACTERISTICS: Impounding reservoirs usually furnish a fairly good quality of water. The water is usually clear, palatable and ranks next to rain water in purity. If the surrounding hills are covered with peat, the pollution of water is very small.:"}

(2) RIVERS
Many rivers furnish a dependable supply of water. Cities such as Delhi, Kolkata and Allahabad rely on river water for their needs. The chief drawback of river water is that it is highly polluted and known to cause diarrhoea drinking without treatment. CHARACTERISTICS: River water is turbid during rainy season; it may be clear in other seasons. Clarity of water is no guarantee that the river water is safe for drinking. River water contains dissolved and suspended impurities of all kinds. The bacterial count, including the human intestinal organisms, may be very high.

IMPURITIES: Rivers are described as a direct connection between the alimentary canal of the people living upstream and the mouths of those below. The impurities of river water are derived from surface washings, sewage and sullage water, industrial and trade wastes, and drainage from agricultural areas. The customs and habits of the people like bathing, animal washing and disposal of the dead, all add to the pollution of water. F. PURIFICATION: Certain amount of self-purification does occur in river water by natural forces of purification such as dilution, sedimentation, evaporation and solar heat, but the water agencies are not sufficient to render the water possible. River water needs purification before it can be used for drinking purposes.

(3) TANKS (5.6)
Tanks are large excavations in which surface water is stored. They are an important source of water supply in some Indian villages. Tanks are recipients of contamination of all sorts. They are full of silt and colloidal matter, especially immediately after the rains. The older tanks may be full of aquatic vegetation. Tanks are often used for washing clothes, utensils, clothes, cocking pots, children use it for swimming and there may be regular defecation around the edges which will be washed into the tank at the next rains. Tanks are thus subjected to unlimited possibilities of contamination and are highly dangerous, as a source of drinking water, even at the best of times. But unfortunately, the tank water is drunk without being boiled, disinfected or having undergone treatment of any kind which is responsible for uncalculable number of cases of sickness and death, particularly if untreated.

Imposition of tanks: A certain amount of natural purification does take place in tank water because of storage, oxidation and other agencies but these are not sufficient to render the water safe. The sanitary quality of tank water may be considerably improved by observing the following:

1. The edges of the tank should be elevated in order to prevent the entry of surface washings. (2) There should be a fence around the tank to prevent access to animals, or one should be permitted to get into the tank directly (note the hazard of geelneworm infection),
(4) there should be an elevated platform from where people can draw water, (5) the weeds should be periodically removed, (6) the tank should be cleaned at the end of the dry season. Inspite of these precautions, from a practical point of view, it is not possible to prevent pollution of tanks as the people who consume the tank water are often among the poorest in the country and do not have sanitary concepts. Considerable research is now in progress at national and international levels to explore the possibility of a safe source of drinking water (5). It is believed that the simplest solution consists of subjecting the tank water to some sort of sand filtration. The addition of chlorine would undoubtedly add to the value of sand filtration.

Sea water

Though this source is plentiful, it has great many limitations. It contains 3.5 per cent of salts in solution. Offshore waters of the oceans and seas have a salt concentration of 30,000 to 36,000 mg/litre (30-36 g/litre) of dissolved solids including 19,000 mg/litre of chloride, 10,600 mg/litre of sodium and 1,270 mg/litre of magnesium. Desalting and demineralization process involves heavy expenditure. It is adopted in places where sea water is the only source available (4).

3. Ground water

Rain water percolating into ground constitutes ground water. Water used by humans comes mainly from land. It is now realized that there is a limit to ground water in the world. We should withdraw only quantities of water that can be renewed.

Ground water is the cheapest and most practical means of providing water to small communities. Ground water is superior to surface water, because the ground itself provides an effective filtering medium. The advantages of ground water are: (1) it is likely to be free from pathogenic agents, (2) it usually requires no treatment, (3) the supply is likely to be certain even during dry season. (4) It is less subject to contamination than surface water. The disadvantages are: (1) it is high in mineral content, e.g., salts of calcium and magnesium which render the water hard (2) it requires pumping or some arrangement to lift the water (7). The usual ground water sources are wells and springs. Wells have been classified into shallow and deep wells. dug and tube wells.

WELLS

Traditionally wells are an important source of water supply. Even today, they are an important source of water supply in many communities. Technically, wells are of two kinds - shallow and deep. (i) Shallow wells: Shallow wells tap subsoil water i.e. the water from above the first impervious layer is the ground. They yield limited quantities of water, and the water is notoriously liable to pollution unless care is taken in well construction. (ii) Deep wells: A deep well is one which taps water from the water-bearing stratum below the first impervious layer in the ground (Fig. 2). Deep wells are usually machine-dug and may be several hundred metres deep. Deep wells furnish the safest water, and are often the most satisfactory sources of water supply.

![FIG. 2 Shallow and deep wells](image-url)

The points of difference between a shallow well and deep well are set out in Table 2.

Most of the wells in India are of the shallow type. Speaking generally, shallow wells are liable to pollution from neighbouring sources of contamination such as latrines, urinals, drains, cesspools, soakage pits and collections of...
manure. Shallow wells are therefore a health hazard to the community if they are not made sanitary. A deep well can also become a health hazard if it is open, poorly constructed and not protected against contamination.

ARTIFICIAL WELLS are a kind of deep wells in which the water rises above the level of ground water, because it is raised under pressure between two impervious strata. Aravian wells are not common in India.

Saline intrusion: Near the sea, there is danger of infiltration of sea water in to deep wells. This gives a brackish taste to water and may make the water unfit for domestic use.

Wells may also be classified, according to the method of construction, into dug wells and tube wells. DUG WELLS are of two kinds: (a) the unlined katcha well and (b) the masonry or pucca well. The katcha well is a hole dug into the water-bearing stratum. The pucca well is an open well, built of bricks or stones. STEPs WELLS are a kind of pucca wells which are becoming obsolete, fortunately. Steps are constructed into these wells to enable people to descend into the well to fetch water or quench their thirst. In these wells, there is considerable personal contact between the user and the water. Some people may even wash their faces, hands and feet which is a common Indian custom. Guineaworm disease is a public health problem in areas where step wells are in use. The open dug wells and step wells are a health hazard to the community.

Improvement of dug wells

The unlined katcha wells may be made sanitary by destroying the infestation and filling the well with coarse sand up to the water level, and with clay above that level. When the material used for filling the pump is consolidated a platform and drainage may be constructed.

Masonry well improvement consists of making the upper 10 feet or more of the lining water-tight, raising the lining one foot above the ground, and providing a reinforced concrete slab cover at the top. One or more hand-pumps may be installed for lifting the water. Special attention should be paid to the foundation of the pump to prevent any possible leakage of waste water into the well.

SANITARY WELL

A sanitary well is one which is properly located, well-constructed and protected against contamination with a view to yield a supply of safe water (Fig. 3). The following points should be taken into consideration while constructing sanitary wells:

1. LOCATION: The first step in well construction is the choosing of a proper site. If bacterial contamination is to be avoided, the well should be located not less than 15 m (50 feet) from likely sources of contamination. The well should be located at a higher elevation with respect to a possible source of contamination. The distance between the well and the houses of the users should also be considered. If the well is situated far away, people may not use it. It is therefore recommended that the well should be so located that no user will have to carry water for more than 100 m (100 yards) (7). (2) LINING: The lining of the well should be built of bricks or stones set in cement up to a depth of at least 6 m (20 feet) so that water enters from the bottom and not from the sides of the well. The lining should be carried 60–90 cm (2–3 feet) above the ground level. (3) PARAPET WALL: There should be a parapet wall up to a height of at least 75–75 cm (28 inches) above the ground. (4) PLATFORM: There should be a cement-concrete platform round the well extending at least 1 m (3 feet) in all directions. The platform should have gentle slope outwards towards a drain built along its edges. (5) DRAIN: There should be a pucca drain to carry off spilled water to a public drain or a seepage pit constructed beyond the "zone of filtration" (area of drainage) of the well. (6) COVERING: The top of the well should be closed by a cement concrete cover because the bulk of the pollution is introduced into the well directly through the open top. Studies have shown that merely covering a well alone caused a marked improvement in the bacteriological quality of the water (5). Open wells, therefore, cannot be considered sanitary, however well they might be constructed otherwise. (7) HAND-PUMP: The well should be equipped with a hand-pump for lifting the water in a sanitary manner. Studies have shown that when a pump is fitted there is marked improvement in the bacteriological quality of the water. The hand-pump should be of robust construction to withstand rough handling by the people. There should be an efficient maintenance service and arrangements for immediate repair if the pumps go out of order. (8) CONSUMER RESPONSIBILITY: The provision
of sanitary wells does not guarantee freedom from water-borne diseases unless the consumers observe certain basic precautions at the individual and family level. Strict cleanliness should be enforced in the vicinity of the well; personal ablutions, washing of clothes and animals, and the dumping of refuse and wastes should be prohibited. Ropes and buckets from individual homes should not be used for drawing a supply from the well. Water from the well should be carried in clean sanitary vessels to individual houses. All this requires health education. (9) QUALITY: The physical, chemical, and bacteriological quality of water should conform to the acceptable standards of quality of safe and wholesome water.

TUBE WELLS

Tube wells are successful as a source of drinking water in many parts of India. They yield water which is bacteriologically safe, and are also cheap in comparison to other sources of supply. Shallow tube wells or "driven wells" have become the largest individual source of water supply to the rural community. The tube well consists of a pipe (usually galvanized iron) sunk into the water-bearing stratum and fitted with a strainer at the bottom, and a hand-pump at the top. A water-tight concrete platform with a drain all round should be provided. The area within 15 m of the tube well should be kept free from pollution with liquid and solid wastes. The hand-pump should be kept in good repair. The life of the tube well is not the same everywhere. It varies from place to place depending upon the type of strainer, quality of underground water and the nature of soil. An average well may last for a period of 5 to 10 years. In some cases, tube wells have given satisfactory service even after 30 years. (8) When the tube well is dereet, it is withdrawn and then re植入 with a new strainer using as much of the withdrawn pipes as can be recovered. Deep tube wells or bored wells are sunk by drilling through successive substrates of gravel or rock until a suitable supply of ground water is located. They may be several hundred feet deep and require complicated mechanical drilling equipment and skilled engineering direction. This type of wells, although costly to construct and to operate, are in many ways the ideal supply. The yield is normally very high and does not depend upon direct rainfall in the immediate vicinity. Chandigarh, the capital of Punjab, derives its entire water supply from tube wells.

SPRINGS

When ground water comes to the surface and flows freely under natural pressure, it is called a "spring". Springs may be of two types—shallow springs and deep springs. Shallow springs dry up quickly during summer months, whereas deep springs do not show seasonal fluctuations in the flow of water. In some geographic areas, springs constitute an important source of water. Springs are simpler to exploit, as no pumping is needed to bring the water to the surface. Springs are exposed to contamination. Well built protective structures are necessary to safeguard water quality.

WATER POLLUTION

Pure uncontaminated water does not occur in nature. It contains impurities of various kinds — natural and man-made. The natural impurities are not essentially dangerous. These comprise dissolved gases (e.g., nitrogen, carbon dioxide, hydrogen sulphide, etc. which may be picked up during rainfall) and dissolved minerals (e.g., salts of calcium, magnesium, sodium, etc.) which are natural constituents of water following its contact with soil; and suspended impurities (e.g., clay, silt, sand and mud), and microscopic organisms. These impurities are derived from the atmosphere, catchment area and the soil.

A more serious aspect of water pollution is that caused by human activity — urbanization and industrialization. The sources of pollution resulting from these are: (a) sewage, which contains decomposable organic matter and pathogenic agents (b) industrial and trade wastes, which contain toxic agents ranging from metal salts to complex synthetic organic chemicals (c) agricultural pollutants, which comprise fertilizers and pesticides, and (d) physical pollutants, viz. heat (thermal pollution) and radioactive substances (9).

The indicators of pollution include the amount of total suspended solids, biochemical oxygen demand (BOD) at 20 deg. C, concentration of chlorides, nitrogen and phosphorous and absence of dissolved oxygen.

Even if the source of water supply and its treatment are of a high standard, water pollution may still occur as often happens, due to corrosion of pipe lines, leaky joints and cross connections between water supply pipes and sewage drainage pipes. Surveillance has to be exercised at every point in the distribution system to ensure supply of safe water to the consumer.

Water-related diseases

Man's health may be affected by the ingestion of contaminated water either directly or through food; and by the use of contaminated water for purpose of personal hygiene and recreation. The term water-related diseases includes the classical water-borne diseases. Developing countries carry a heavy burden of water-related diseases, the heaviest being the diarrhoeal diseases. Water-related diseases may be classified as follows:

A. Biological (Water-borne diseases)

1. Those caused by the presence of an infusitive agent:
   (a) Viral: 
   - Viral hepatitis A, hepatitis E, poliomyelitis, rotavirus diarrhea in infants
   (b) Bacterial: 
   - typhoid and paratyphoid fever, bacillary dysentery, E.coli diarrhea, cholera
   (c) Protozoal: amebiasis, giardiasis
   (d) Helminthic: roundworm, threadworm, hydatid disease.
   (e) Leptospiral: well's disease

2. Those due to the presence of an aquatic host:
   (a) Snails: schistosomiasis
   (b) Cystics: guinea worm, fish tape worm.

B. Chemical

Chemical pollutants of diverse nature derived from industrial and agricultural wastes are increasingly finding their way into public water supplies. These pollutants include detergent solvents, Cu, Ni, Fe, Pb, Cd, Zn, Cu, As, Hg, Mn; nitrates, sulphates, ammonia, and toxic and biocidal organic compounds of great variety. Chemical pollutants may affect man's health not only directly, but also indirectly by accumulating in aquatic life (e.g. fish) used as human food. The present concern about chemical pollutants
in water relates not so much as to their acute toxic effects on human health as to the possible long-term effects of low-level exposure, which are often non-specific and difficult to detect. Further, some of the new pollutants are not easily removed by conventional water treatment or purification processes. In many developing countries where water-borne communicable diseases have virtually disappeared, more attention is now being paid to chemical pollution.

In addition to the above, water is associated with the following:

- **Dental health**: The presence of fluoride at about 1 mg/litre in drinking water is known to protect against dental caries but high levels of fluoride cause mottling of the dental enamel.

- **Cyanosis in infants**: High nitrate content of water is associated with methaemoglobinaemia. This is a rare occurrence but may occur when surface water from farmland, treated with a fertilizer, gains access to the water supply.

- **Cardiovascular diseases**: Hardness of water appears to have a beneficial effect against cardiovascular diseases.

- **Some diseases are transmitted because of inadequate use of water like shigellosis, trachoma and conjunctivitis, ascariasis, scabies (10).**

- **Some diseases are related to the disease carrying insects breeding in or near water, like**: malaria, filaria, arboviruses, anophelias. African trypanosomiasis (10).

While pollution seems to be an inevitable consequence of modern industrial technology, the problem, now, is to determine the level of pollution that permits economic and social development without adverse impacts to health. The evaluation of the health effects of environmental pollutants is currently being carried out as part of the WHO Environmental Health Criteria Programme.

**WATER POLLUTION LAW**

In India, water pollution is becoming a serious problem. To protect water from being contaminated, the Indian Parliament in 1974 passed the Water (Prevention and Control of Pollution) Act. The Act seeks to provide legal deterrent against the spread of water pollution. The Act is a comprehensive piece of legislation. It provides for the constitution of Central and State Water Boards and Joint Water Boards endowed with wide powers for controlling pollution.

**PURIFICATION OF WATER**

Purification of water is of great importance in community medicine. It may be considered under two headings:

1. **Purification of water on a large scale.**
2. **Purification of water on a small scale.**

**1. PURIFICATION OF WATER ON A LARGE SCALE**

The purpose of water treatment is to produce water that is safe and wholesome. The method of treatment to be employed depends upon the nature of raw water, and the desired standards of water quality. For example, ground water (e.g., wells and springs) may need no treatment, other than disinfection. Surface water (e.g., river water) which tends to be turbid and polluted, requires extensive treatment. The components of a typical water purification system comprise one or more of the following measures:

- **Storage**
- **Filtration**
- **Disinfection**

**I) Storage**

Water is drawn out from the source and impounded in natural or artificial reservoirs. Storage provides a reserve of water from which further pollution is excluded. As a result of storage, a very considerable amount of purification takes place. This is natural purification, and we may look at it from three points of view: (a) Physical: By mere storage, the quality of water improves. About 90 per cent of the suspended impurities settle down in 24 hours by gravity. The water becomes clearer. This allows penetration of lights, and reduces the work of the filters. (b) Chemical: Certain chemical changes also take place during storage. The aerobic bacteria oxidize the organic matter present in the water with the aid of dissolved oxygen. As a result, the content of free ammonia is reduced and a rise in nitrates occurs. (c) Biological: A tremendous drop takes place in bacterial count during storage. The pathogenic organisms gradually die out. It is found that when river water is stored the total bacterial count drops by as much as 90 per cent in the first 5–7 days. This is one of the greatest benefits of storage. The optimum period of storage of river water is considered to be about 10–14 days. If the water is stored for long periods, there is likelihood of development of vegetable growths such as algae which impart a bad smell and colour to water.

**II) Filtration**

Filtration, the second stage in the purification of water, and quite an important stage because 96–99 per cent of the bacteria are removed by filtration, apart from other impurities. Two types of filters are in use, the "biological" or "slow sand" filters and the "rapid sand" or "mechanical" filters. A brief description of these filters is given below:

**SLOW SAND OR BIOLOGICAL FILTERS (11)**

Slow sand filters were first used for water treatment in 1804 in Scotland and subsequently in London. During the 19th century their use spread throughout the world. Even today, they are generally accepted as the standard method of water purification.

Elements of a slow sand filter

![Diagram](https://via.placeholder.com/150)

- (1) **Superintendant (raw) water**
- (2) a bed of graded sand
- (3) an under-drainage system; and
- (4) a system of filter control valves.

**1) Superintendant water**

The superintendant water above the sand bed, whose depth varies from 1 to 1.5 metre, serves two important purposes: it provides a constant head of water so as to overcome the resistance of the filter bed and thereby promote the downward flow of water through the sand bed; and, secondly, it provides waiting period of some hours (3 to 12 hours, depending upon the filtration velocity) for the raw water to undergo partial purification by sedimentation.
oxidation and particle agglomeration. The level of supernatant water is always kept constant.

2) Sand bed

The most important part of the filter is the sand bed. The thickness of the sand bed is about 1 metre. The sand grains are carefully chosen so that they are preferably rounded and have an “effective diameter” between 0.2 and 0.3 mm. The sand should be clean and free from clay and organic matter. The sand bed is supported by a layer of graded gravel (Fig. 5), 30–40 cm deep which also prevents the fine grains being carried into the drainage pipes.

The sand bed presents a vast surface area; one cubic metre of filter sand contains some 15,000 sq. metres of surface area. Water percolates through the sand bed very slowly (a process taking two hours or more), and as it does so, it is subjected to a number of purification processes – mechanical straining, sedimentation, adsorption, oxidation and bacterial action, all playing their part. The designed rate of filtration of water normally lies between 0.1 and 0.4 m³/hour/per square metre of sand bed surface.

Vital layer: When the filter is newly laid, it acts merely as a mechanical strainer, and cannot truly be considered as “biological”. But very soon, the surface of the sand bed gets covered with a slimy growth known as “Schmutzdecke”, vital layer, zoogloeal layer or biological layer. This layer is slimy and gelatinous and consists of thread-like algae and numerous forms of life including plankton, diatoms and bacteria. The formation of vital layer is known as “ripening” of the filter. It may take several days for the vital layer to form fully, and when fully formed it extends for 2 to 3 cm into the top portion of the sand bed. The vital layer is the “heart” of the slow sand filter. It removes organic matter, holds back bacteria and oxidizes ammoniacal nitrates into nitrates and helps in yielding a bacteria-free water. Until the vital layer is fully formed, the first few days filtrate is usually run to waste.

3) Under-drainage system

The under-drainage system consists of porous or perforated pipes which serve the dual purpose of providing an outlet for filtered water, and supporting the filter medium above. Once the filter bed has been laid, the under-drainage system cannot be seen.

Filter box: The first 3 elements (e.g. supernatant water, sand bed and under-drainage system) are contained in the filter box. The filter box is an open box, usually rectangular in shape, from 2.5 to 4 metres deep and is built wholly or partly below ground. The walls may be made of stone, brick or cement. The filter box consists from top to bottom:

- Supernatant water: 1 to 1.5 metre
- Sand bed: 1.2 metre
- Gravel support: 0.30 metre
- Filter bottom: 0.16 metre

4) Filter control

The filter is equipped with certain valves and devices which are incorporated in the outlet-pipe system. The purpose of these devices is to maintain a constant rate of filtration. An important component of the regulation system is the “Venturi meter” (Fig. 4) which measures the bed
resistance or "loss of head". When the resistance builds up, the operator opens the regulating valve so as to maintain a steady rate of filtration. When the "loss of head" exceeds 1.3 metre it is uneconomical to run the filter.

Filter cleaning: Normally the filter may run for weeks or even months without cleaning. When the bed resistance increases to such an extent that the regulating valve has to be kept fully open, it is time to clean the filter bed, since any further increase in head is bound to reduce the filtration rate. At this stage, the supernatant water is drained off, and the sand bed is cleaned by "scraping" off the top portion of the sand layer to a depth of 1 or 2 cm. This operation may be carried out by unskilled labourers using hand tools or by mechanical equipment. After several years of operation, and say 20 or 30 scappings, the thickness of the sand bed still has to be reduced to about 0.5 to 0.8 metre. Then the plant is closed down and a new bed is constructed.

The advantages of a slow sand filter are : (1) simple to construct and operate (2) the cost of construction is cheaper than that of rapid sand filters (3) the physical, chemical and bacteriological quality of filtered water is very high. When working ideally, slow sand filters have been shown to reduce total bacterial counts by 99.9 to 99.99 per cent and E. coli by 99 to 99.9 per cent. In recent years, a mistaken idea has grown that biological or slow sand filtration is an old fashioned, outdated method of water treatment which has been completely superseded by rapid sand filtration. This is definitely not the case. Slow sand filtration is still the chosen method of water purification in a number of highly industrialized cities as well as urban areas. In a number of cities in U.S. and Europe, slow sand filters have recently been constructed.

RAPID SAND OR MECHANICAL FILTERS

In 1885, the first rapid sand filters were installed in the USA. Since that time, they have gained considerable popularity especially in countries with high rainfall. Rapid sand filters are of two types, the gravity type (e.g. Paterson's filter) and the pressure type (e.g. Cundy's filter). Both the types are in use. The following steps are involved in the purification of water by rapid sand filters : (Fig. 5).

1. Coagulation : The raw water is first treated with a chemical coagulant such as alum, the dose of which varies from 5 to 40 mg per cubic metre, depending upon the turbidity and colour, temperature and the pH value of the water.
2. Rapid mixing : The treated water is then subjected to violent agitation in a "mixing chamber" for a few minutes. This allows a quick and thorough dissemination of alum throughout the bulk of the water, which is very necessary.
3. Flocculation : The next phase involves a slow and gentle stirring of the treated water in a "flocculation chamber" for about 30 minutes. The mechanical type of flocculator is the most widely used. It consists of a number of paddles which rotate at 2 to 4 rpm. The paddles rotate with the help of motors. This slow and gentle stirring results in the formation of a thick, coagulated, white flocculent precipitate of aluminium hydroxide. The thicker the precipitate or floc diameter, the greater the settling velocity.
4. Sedimentation : The coagulated water is now led into sedimentation tanks where it is detained for periods varying from 8-6 hours when the flocculent precipitate together with impurities and bacteria settle down in the tank. At least 95 per cent of the flocculent precipitate needs to be removed before the water is admitted into the rapid sand filters. The precipitate or sludge which settles at the bottom is removed from time to time without disturbing the operation of the tank. For proper maintenance, the tank should be cleaned regularly from time to time, otherwise they may become a breeding ground for molluscs and snails.

5. Filtration : The partly clarified water is now subjected to rapid sand filtration.

Filter beds

Each unit of Filter bed has a surface of about 80 to 90 m² (about 900 sq. feet). Sand is the filtering medium. The "effective size" of the sand particles is between 0.4-0.7 mm. The depth of the sand bed is usually about 1 metre (2 ½ to 3 feet). Below the sand bed is a layer of graded gravel, 30 to 40 cm. (1-1½ feet) deep. The gravel supports the sand bed and permits the filtered water to move freely towards the under-drains. The depth of the water on the top of the sand bed is 1.0 to 1.5 m (5-6 feet). The under-drains at the bottom of the filter beds collect the filtered water. The rate of filtration is 5-15 m³/min/ha. A view of the rapid sand filter is shown in Fig. 7.

---

**FIG. 6**

Flow diagram of a rapid sand filtration plant

---

**FIG. 7**

A view of a rapid sand filter
Filtration
As filtration proceeds, the “slum-floc” not removed by sedimentation is held back on the sand bed. It forms a slinky layer comparable to the zoogloal layer in the slow sand filters. It absorbs bacteria from the water and effects purification. Oxidation of ammonia also takes place during the passage of water through the filters. As filtration proceeds, the suspended impurities and bacteria clog the filters. The filters soon become dirty and begin to lose their efficiency. When the “loss of head” approaches 7–8 ft, filtration is stopped and the filters are subjected to a washing process known as “backwashing”.

Backwashing
Rapid sand filters need frequent washing daily or weekly, depending upon the loss of head. Washing is accomplished by reversing the flow of water through the sand bed, which is called “backwashing.” Backwashing dissolves the impurities and cleans up the sand bed. The washing is stopped when clear sand is visible and the wash water is sufficiently clear. The whole process of washing takes about 15 minutes. In some rapid sand filters, compressed air is used as part of the backwashing processes.

Advantages
The advantages of a rapid sand filter over the slow sand filter are as follows:

- The filter beds occupy less space (3) filtration is rapid, 40–50 times that of a slow sand filter (4) washing of the filter is easy (5) there is more flexibility in operation.

Comparison of rapid and slow sand filters
The main features of rapid and slow sand filters are as given in Table 3.

(III) Disinfection
For a chemical or an agent to be potentially useful as a disinfectant to water supplies, it has to satisfy the following criteria:

- (a) It should be capable of destroying the pathogenic organisms present, within the contact time available and not unduly influenced by the range of physical and chemical properties of water, especially particularly temperature, pH and mineral constituents;
- (b) Should not leave products of reaction which render the water toxic or impair colour or otherwise make it unpleasant.

(c) Have ready and dependable availability at reasonable cost permitting convenient, safe and simple and amenable to detection by practical, rapid and simple analytical techniques in the small concentration ranges to permit the control of the efficiency of the disinfection process.

In water works practice, the term disinfection is synonymous with chlorination.

CHLORINATION
Chlorination is one of the greatest advances in water purification. It is supplement, not a substitute to sand filtration. Chlorine kills pathogenic bacteria, but is has no effect on viruses and certain viruses (e.g., polio, viral hepatitis) except in high doses. Apart from its germicidal effect, chlorine has several important secondary properties of value in water treatment: it oxidises iron, manganese and hydrogen sulphide; it destroys some taste and odour-producing constituents; it controls algae and slime organisms; and aids coagulation.

Action of chlorine: When chlorine is added to water, there is formation of hydrochloric acid and hypochlorous acid. The hydrochloric acid is neutralized by the alkalinity of the water. The hypochlorous acid ionizes to form hydrogen ions and hypochlorite ions, as follow:

\[ \text{H}_2\text{O} + \text{Cl}_2 \rightarrow \text{H}^+ + \text{HOCI} \]

The disinfecting action of chlorine is mainly due to the hypochlorous acid and to a small extent due to the hypochlorite ions. The hypochlorous acid is the most effective (70–80%) than the hypochlorite ion. Chlorine acts best as a disinfectant when the pH of water is around 7 because of the predominance of hypochlorous acid. When the pH value exceeds 8.5 it is unreliable as a disinfectant because about 90% per cent of the hypochlorous acid gets ionized to hypochlorite ions. It is fortunate that most waters have a pH value between 6–7.5.

Principles of chlorination: The mere addition of chlorine to water is not chlorination. There are certain rules which should be obeyed in order to ensure proper chlorination:

- (1) First of all, the water to be chlorinated must be clear and free from turbidity. Turbidity impedes efficient chlorination. (2) Similarly, the “chlorine demand” of the}

water should be estimated. "The chlorine demand of water is the difference between the amount of chlorine added to the water, and the free chlorine remaining at the end of a specific period of contact (usually 60 minutes), at a given temperature and pH of the water". In other words, it is the amount of chlorine that is necessary to destroy bacteria, and to oxidize all the organic matter and ammoniacal substances present in the water. The point at which the chlorine demand of the water is met is called the "break-point". If further chlorine is added beyond the break point, free chlorine (HOCl and OCI) begins to appear in the water (3). This is the contact period. The presence of free residual chlorine for a contact period of at least one hour is essential to kill bacteria and viruses (20). It should be noted however, that chlorine has no effect on spores, protozoan cysts and helminthic ova, except in higher doses. (4) The minimum recommended concentration of free chlorine is 0.5 mg/l for one hour (12). The free residual chlorine provides a margin of safety against subsequent microbial contamination such as may occur during storage and distribution. (5) The sum of the chlorine demand of the specific water plus the free residual chlorine of 0.5 mg/l constitutes the correct dose of chlorine to be applied. METHOD OF CHLORINATION

For disinfecting large bodies of water, chlorine is applied either as (1) chlorine gas (2) chloramine or (3) perchloron. Chlorine gas is the first choice, because it is cheap, quick in action, efficient and easy to apply. Since chlorine gas is an irritant to the eyes and poisonous, a special equipment known as "chlorinating equipment" is required to apply chlorine gas to water supplies. Perchloron is one of such device for measuring, regulating and administering gaseous chlorine to water supplies. In some water treatment plants, they may use chloramine instead of chlorine gas. Chloramines are loose compounds of chlorine and ammonia. They have a less tendency to produce chlorinous tastes and give a more permanent type of residual chlorine. The greatest drawback of chloramines is that they have a slower action than chlorine and therefore they are not being used to any great extent in water treatment. Perchloron or high test hypochlorite (H.T.H.) is a calcium compound which carries 60-70 percent of available chlorine. Solutions prepared from H.T.H. are used for water disinfection. As mentioned already, chlorine gas has replaced all the other chlorine derivatives in the disinfection of urban water supplies.

BREAK POINT CHLORINATION

The addition of chlorine to ammonium in water produces chloramines which do not have the same efficiency as free chlorine. If the chlorine dose in the water is increased, a reduction in the residual chlorine occurs, due to the destruction of chloramine by the added chlorine. The end products do not represent any residual chlorine. This fall in residual chlorine will continue with further increase in chlorine dose and after a stage, the residual chlorine begins to increase in proportion to the added dose of chlorine. This point at which the residual chlorine appears and when all combined chlorines have been completely destroyed is the break point and corresponding dosage is the breakpoint dosage. Breakpoint chlorination achieves the same results as superchlorination in a rational manner and can therefore be construed as controlled superchlorination (4).

SUPERCHLORINATION

Superchlorination followed by dechlorination comprises the addition of large doses of chlorine to the water, and removal of excess of chlorine after disinfection, this method is applicable to heavily polluted waters whose quality fluctuates greatly.

ORTHOTOLIDINE (O-T) TEST

Orthotolidine test enables both free and combined chlorine in water to be determined with speed and accuracy. The test was developed by Dr. G. F. Wettstein and the analytical grade Orthotolidine, dissolved in 10 per cent solution of hydrochloric acid. When this reagent is added to chlorinated water in a dilute yellow and the intensity of the colour varies with the concentration of the gas. The yellow colour is produced by both free and combined chlorine. O-T reacts with free chlorine instantaneously but reacts more slowly with combined chlorine (12).

The test is carried out by adding 0.1 ml of the reagent to 1 ml of water. The yellow colour produced is matched against suitable standards or colour discs. Commercial equipment is available for this purpose. It is essential to take the reading within 10 seconds after the addition of the reagent to estimate free chlorine in water (14). The colour that is produced after a lapse, say 15-20 minutes, is due to the action of both free and combined chlorine.

ORTHOTOLIDINE-ARSENITE (O-TA) TEST

This is a modification of the O-T test to determine the free and combined chlorine residues separately (13, 14, 15). Further, the errors caused by the presence of interfering substances as nitrites, iron and manganese all of which produce a yellow colour with Orthotolidine, are overcome by the O-TA test (12).

Other agents

While chlorine continues to be the most commonly used sterilizing agent because of its germicidal properties and the comparatively low cost and ease of application, its pre-eminence in water disinfection is being seriously challenged because of the discovery that chlorination of water can lead to the formation of many "halogenated compounds" some of which are either known or suspected carcinogens. As a result, many chlorine alternatives are receiving renewed interest. These include bromine, bromine-chloride, iodine and chlorine dioxide - but these do not seem to present a viable alternative to chlorine at the present time. Ozone is showing the greatest promise, and ultra-violet irradiation's limited usefulness as complementary agents for chlorine water disinfectant.

Ozonation (19)

Ozone is a powerful oxidant and has many uses in water treatment, including oxidation of organic chemicals. Ozone can be used as a primary disinfectant. Ozone gas (O3) is formed by passing dry air or oxygen through a high-voltage electric field. The resultant ozone-enriched air is dosed directly into the water by means of porous diffusers at the base of baffled contactor tanks. The contactor tanks, typically about 5 metre deep, provide 10-20 minutes of contact time. Dissolution of almost 80% of the applied ozone should be possible, with the remainder contained in the off-gas, which is passed through an ozone destructor and vents to the atmosphere.

The performance of ozonation relies on achieving the desired concentration after a given contact period. For
oxidation of organic chemicals, such as some oxidizable pesticides, a residual of about 0.5 mg/l after a contact time of 20 min in contact with disinfectant is typically used.  These doses are required to achieve this level of removal of water disinfection.  Changes in the demand for the treatment of drinking water.

Membrane processes (19)
The membrane processes of most significance in water treatment are reverse osmosis, ultratration, microfiltration and nanofiltration. These processes have traditionally been applied to the treatment of water for industrial or pharmaceutical applications, but are now being applied to the treatment of drinking water.

High-pressure processes
If two solutions are separated by a semi-permeable membrane (i.e., a membrane that allows the passage of the solvent but not of the solute), the solvent will naturally pass from the lower-concentration solution to the higher-concentration solution. This process is known as osmosis. It is possible, however, to force the flow of solvent in the opposite direction, from the higher to the lower concentration, by increasing the pressure on the higher-concentration solution. The required pressure differential is known as the osmotic pressure, and the process is known as reverse osmosis.

Reverse osmosis results in the production of a treated water stream and a relatively concentrated waste stream. Typical operating pressures are in the range 15-50 bar, depending on the application. Reverse osmosis rejects monovalent ions and organic molecules of molecular weight greater than about 50 daltons (membrane pore sizes are less than 0.002 μm). The most common application of reverse osmosis is desalination of brackish water and seawater.

Nanofiltration uses a membrane with properties between those of reverse osmosis and ultrafiltration membranes; pore sizes are typically 0.001-0.01 μm. Nanofiltration membranes allow monovalent ions such as sodium or potassium to pass but reject a high proportion of divalent ions such as calcium and magnesium and some higher molecular weight organic molecules. Operating pressures are typically about 5 bar. Nanofiltration may be effective for the removal of colour-forming organic compounds also.

Low-pressure processes
Ultrafiltration is similar in principle to reverse osmosis, but the membranes have much larger pore sizes (typically 6.002-0.03 μm) and operate at lower pressures. Ultrafiltration membranes reject organic molecules of molecular weight above about 800 daltons and usually operate at pressure less than 5 bar.

Microfiltration is a direct extension of conventional filtration into the sub-micrometre range. Microfiltration membranes have pore sizes typically in the range 0.01-12 μm and do not separate molecules but reject colloidal and suspended material at operating pressures of 1-5 bar.

Microfiltration is capable of sieving out particles greater than 0.05 μm. It has been used for water treatment in combination with other processes, such as adsorption, to remove dissolved organic carbon prior to reverse osmosis membranes and to improve permeate flux.

2. PURIFICATION OF WATER ON A SMALL SCALE

(1) Household purification of water
Three methods are generally available for purifying water on an individual or domestic scale. These methods can be used singly or in combination.

(a) BOILING
Boiling is a simple method of purifying water for household purposes. To be effective, the water must be brought to a rapid boil for 10 to 20 minutes. It kills all bacteria, spores, cysts and viruses and sterilizes water. Boiling also removes temporary hardness by driving off carbon dioxide and precipitating the calcium carbonate. The taste of water is altered, but this is harmless. While boiling is an excellent method of purifying water, it offers no "residual protection" against subsequent microbial contamination. Water should be boiled preferably in the same container in which it is to be stored to avoid contamination during storage.

(b) CHEMICAL DISINFECTION
(1) Bleaching powder: Bleaching powder (CaOCl₂) is a white amorphous powder with a pungent smell of chlorine. When weakly made, it contains about 33 per cent of "available chlorine". It is, however, an unstable compound. Exposure to light, air and moisture, it rapidly loses its chlorine content. But when mixed with excess of lime, it retains its strength, this is called "stabilized bleach." Bleaching powder should be stored in a dark, cool, dry place in a closed container that is resistant to corrosion. The chlorine content of bleaching powder stocks should be frequently checked.

Appendix III gives in a tabular form the amount of bleaching powder required to disinfect certain quantities of water. The principle in chlorination is to give a free residual chlorine of 0.5 mg/l at the end of one hour contact. Highly polluted and turbid waters are not suitable for direct chlorination.

(2) Chlorine solution: Chlorine solution may be prepared from bleaching powder. If 4 kg of bleaching powder with 25 per cent available chlorine is mixed with 20 litres of water, it will give a 5 per cent solution of chlorine (13). Ready-made chlorine solutions in different strengths are also available in the market. Like bleaching powder, the chlorine solution is subject to loss on exposure to light and on prolonged storage. The solution should be kept in a dark, cool and dry place in a closed container.

(3) High test hypochlorite: High test hypochlorite (HTH) or perchloron is a calcium compound which contains 60 to 70 per cent available chlorine. It is more stable than bleaching powder and deteriorates much less on storage. Solutions prepared from HTH are also used for water disinfection. Appendix III (page 730) shows the amount of HTH needed to disinfect certain quantities of water.
(4) Chlorine tablets: Under various trade names (viz., halazone tablets) are available in the market. They are quite good for disinfecting small quantities of water, but they are costly. The National Environmental Engineering Research Institute, Nagpur formulated a new type of chlorine tablet which is 15 times safer than ordinary chlorine tablets. These tablets are manufactured in various strengths and are now available in plenty, in the Indian market at a cheap rate. A single tablet of 0.5 g suffices to disinfect 20 litres of water.

(5) Iodine: Iodine may be used for emergency disinfection of water. Two drops of 2 per cent ethanol solution of iodine will suffice for one litre of clear water. A contact time of 20 to 30 minutes is needed for effective disinfection. Iodine does not react with ammonia or organic compounds to any great extent; hence it remains in its active molecular form, over a wide range of pH values and water conditions and persists longer than either chlorine or bromine. Iodine is unlikely to become a municipal water supply disinfectant in a broad sense. High costs and the fact that the element is physiologically active (thyroid activity) are its major disadvantages (17).

(6) Potassium permanganate: Once widely used it is no longer recommended for water disinfection. Although a powerful oxidizing agent, it is not a satisfactory agent for disinfecting water. It may kill cholera vibrios, but is of little use against other disease organisms (15). It has other drawbacks, too, such as altering the colour, smell and taste of water.

(c) FILTRATION
Water can be purified on a small scale by filtering through ceramic filters such as Pasteur Chamberland filter, Berkfeld filter and "Katadyn" filter. The essential part of a filter is the "candle" which is made of porcelain in the Chamberland type, and of kneesight or "cristalline" earth in the Berkfeld filter (Fig. 8). In the Katadyn filter, the surface of the filter is coated with a silver catalyzer so that bacteria coming in contact with the surface are killed by the "oligodynamic" action of the silver ions, which are liberated into the water. Filter candles of the fine type usually remove bacteria found in drinking water, but not the filter-passing viruses. Filter candles are liable to be logged with impurities and bacteria. They should be cleaned by scrubbing with a hard brush under running water and boiled at least once a week. Only clean water should be used with ceramic filters. Although ceramic filters are effective in purifying water, they are not quite suitable for widespread use under Indian conditions.

FIG. 8
Berkfeld filter

(d) ULTRAVIOLET IRRADIATION
Carcinoidal property of UV rays has been recognized for many years. UV irradiation is effective against most microorganisms known to contaminate water supplies like bacteria, yeast, viruses, fungi, algae, protozoa etc.

This method of disinfection involves the exposure of a film of water, up to about 120 mm thick, to one or several quartz mercury vapour arc lamps emitting ultraviolet radiation at a wavelength of 254 (Nano-metre). Applications are limited to individual or institutional systems. The water should be free from turbidity and suspended or colloidal constituents for efficient disinfection.

The advantages are that the exposure is for short period, no foreign matter introduced and no taste or colour produced. Overexposure does not result in any harmful effects. The disadvantages are that no residual effect is available and there is a lack of a rapid field test for assessing the treatment efficiency; no recorder, the apparatus needed is expensive.

(e) MULTI-STAGE REVERSE OSMOSIS PURIFICATION OF WATER
Multistage reverse osmosis purification process is used to make water both chemically and microbiologically potable by removing the total dissolved solids, hardness, heavy metals and disease causing bacteria, virus, protozoa and cysts.

The Fig. 9 shows the diagrammatic form and the various elements of a typical multistage reverse osmosis process. The clarity cartridge removes the suspended particles such as dust, mud and sand from the water. The Reverse osmosis cartridge reduces the total dissolved solids, hardness, heavy metals (like arsenic, lead, mercury) and eliminates micro-organisms.

(2) Disinfection of wells
Wells are the main source of water supply in the rural areas. The need often arises to disinfect them, sometimes on a mass scale, during epidemics of cholera and gastroenteritis. The most effective and cheapest method of disinfecting wells is by bleaching powder. Potassium permanganate should not be used, as it is not a satisfactory disinfecting agent.

STEPS IN WELL DISINFECTION
(1) Find the volume of water in a well
(a) Measure the depth of water column ... (h) metre
(b) Measure the diameter of well ... (d) metre
Take the average of several readings of the above measurements.
(c) Substitute h and d in: Volume (litres) = \[ \frac{3.14 \times d^2 \times h}{4} \times 1000 \]
(d) One cubic metre = 1,000 litres of water

(2) Find the amount of bleaching powder required for disinfection
Estimate the chlorine demand of the well water by "Horrocks's Apparatus (vide Annex I) and calculate the amount of bleaching powders required to disinfect the well. Annex-III gives the amount of chemicals needed to disinfect water for drinking. Roughly, 2.5 grams of good quality
bleaching powder would be required to disinfect 1,000 litres of water. This will give an approximate dose of 0.7 mg of applied chlorine per litre of water.

(3) Dissolve bleaching powder in water

The bleaching powder required for disinfecting the well is placed in a bucket (not more than 100 g in one bucket of water) and made into a thin paste. More water is added till the bucket is nearly three-fourths full. The contents are stirred well, and allowed to sediment for 5 to 10 minutes when the supernatant solution which is chlorine solution, is transferred to another bucket, and the chalk or lime is discarded. (Note: the lime sediment should not be poured into the well, as it increases the hardness of well water).

(4) Delivery of chlorine solution into the well

The bucket containing the chlorine solution is lowered some distance below the water surface, and the well water is agitated by moving the bucket violently both vertically and laterally. This should be done several times so that the chlorine solution mixes intimately with the water inside the well.

(5) Contact period

A contact period of one hour is allowed before the water is drawn for use.

(6) Orthotolidine arsenite test

It is good practice to test for residual chlorine at the end of one hour contact. If the "free" residual chlorine level is less than 0.5 mg/litre, the chlorination procedure should be repeated before any water is drawn. Wells are best disinfected at night after the day's draw off. During epidemics of cholera, wells should be disinfected every day.

The double pot method (13, 18)

During an emergency, it is desirable to ensure a constant dosage of chlorine to well water. Several simple and effective methods have been devised for this purpose, of which the pot method of chlorination is one which has been used with success in various countries. The double pot method is an improvement devised by the National Environmental Engineering Research Institute, Nagpur, India. This method uses two cylindrical pots, one placed inside the other. The inside height and diameter are 30 cm and 25 cm respectively, for the outer pot. A hole 1 cm in diameter is made in each pot; in the inner pot the hole is in the upper portion, near the rim and in the outer pot it is 4 cm above the bottom.

A mixture of 1 kg of bleaching powder and 2 kg of coarse sand (approx. 2 mm in diameter) is prepared and slightly moistened with water. The inner pot is filled with this mixture up to 3 cm below the level of the hole. The inner pot is introduced into the outer one, and the mouth of the latter closed with polyethylene foil. The use of two pots makes it possible to have larger holes without the risk of over chlorination.
The double pot is lowered into the well by means of a rope attached to the well head. The pot should be immersed at least 1 m below the water level to prevent damage by the buckets used for drawing water. It has been found that this device works satisfactorily for 2–3 weeks in small household wells containing about 400–500 litres of water and having a draw-off rate of 360–450 litres per day.

WATER QUALITY – CRITERIA AND STANDARDS

The quest for pure water dates back to antiquity. In modern times, it has led to the formulation of specific standards to provide a basis for judging the quality of water. These standards are exposure limits for bacteriological, viral, chemical, and physical agents that have been adopted by governments or appropriate authorities and therefore have legal force. The purpose of standards is to minimise all the known health hazards, since it is obviously impossible to prevent all pollution.

The WHO has published in 1993 vol.1 and in 1996 vol. 2 of second edition, and more recently vol. I and II in 2011 of guidelines for drinking water quality intended for use by countries as a basis for the development of standards, which, if properly implemented, will ensure the safety of drinking water supplies. In order to define standards, it is necessary to consider these recommendations in the context of prevailing environmental, social, economic and cultural conditions. These guidelines are intended to supersede the guidelines for drinking water published in 1984 (19).

The guidelines for drinking water quality recommended by WHO (2011) relate to following variables:

1. Acceptability aspects
2. Microbiological aspects
3. Chemical aspects
4. Radiological aspects.

1. ACCEPTABILITY ASPECTS

A. Physical parameters

The ordinary consumer judges the water quality by its physical characteristics. The provision of drinking water that is not only safe but also pleasing in appearance, taste and odour is a matter of high priority. The supply of water that is unsatisfactory in this respect will undermine the confidence of consumers, leading to use of water from less safe source. The acceptability of drinking water can be influenced by many different constituents. These are:

1. Turbidity: On aesthetic grounds, drinking water should be free from turbidity. Turbidity in drinking water is caused by particulate matter that may be present as a consequence of inadequate treatment or from re-suspension of sediment in the distribution system. It may also be due to the presence of inorganic particulate matter in some ground water. Turbidity interferes with disinfection and microbiological determination. Water with turbidity of more than 4 nephelometric turbidity units (NTU) is usually noticeable to the naked eye.

2. Colour: Drinking water should be free from colour which may be due to the presence of coloured organic matter (primarily humic substances), metals such as iron and manganese, or highly coloured industrial wastes. Consumers may turn to alternative, perhaps unsafe, sources when their water is coloured in an aesthetically displeasing degree. The guideline value is up to 15 true colour units (TCU) although levels of colour above 15 TCU can be detected in a glass of water.

3. Taste and odour: Taste and odour originate from natural or artificial sources or from pollution contamination by chemicals, or as a by-product of water treatment (e.g., chlorination). Taste and odour may develop during storage and distribution. Its indication of some degree of pollution or malfunction during water treatment or distribution. The cause should be investigated, particularly if there is a substantial change. An unusual taste or odour might be an indication of the presence of potentially harmful substances. No health based guideline value is proposed for taste and odour.

4. Temperature: Cool water is generally more palatable. Low water temperature tends to decrease the efficiency of treatment processes, including disinfection, and may thus have a deleterious effect on drinking water quality. However, high water temperature enhances the growth of micro-organisms and taste, odour, colour and corrosion problems may increase. No guideline value is recommended since its control is usually impracticable.

To sum up, we cannot judge the quality of drinking water by physical characteristics alone. A detailed chemical and microbiological examination is also needed for complete assessment.

B. Inorganic constituents

1. Chlorides: All waters including rain water contain chlorides. In the neighbourhood of the sea, the salinity of water tends to be high. Since the chloride content of water varies from place to place, it is necessary, first of all, to determine the normal range of chlorides of the unpolluted surface and ground water in the given locality. Any excess over the normal range should arouse suspicion of water contamination. The standard prescribed for chloride is 200 mg/litre. The maximum permissible level is 600 mg/litre.

2. Hardness: Public acceptability of the degree of hardness may vary considerably from one community to another, depending on local conditions. The taste threshold for the calcium ion is in the range of 100–300 mg/litre, depending on the associated anion, and the taste threshold of magnesium is probably less than that for calcium. In some instances water hardness in excess of 500 mg/litre is tolerated by consumers. Depending on the interaction of other factors, such as pH and alkalinity, water with a hardness of approximately 200 mg/litre may cause scale deposition in the distribution system and will result in excessive soap consumption and subsequent scum formation. On heating, hard water forms deposits of calcium carbonate scale. Soft water, with a hardness of less than 100 mg/litre, may, on the other hand, have a low buffer capacity and so be more corrosive for water pipes (19).

3. Ammonia: The term ammonia includes the non-ionised (NH₃) and ionized (NH₄⁺). Ammonia in the environment originates from metabolic, agricultural and industrial processes and from disinfection with chloramine. Natural levels in ground and surface waters are usually below 0.2 mg/litre. Anaerobic ground waters may contain up to 3mg/litre. Intensive rearing of farm animals can give rise to much higher levels in surface water. Ammonia contamination can also arise from cement mortar pipe linings. Ammonia in water is an indicator of possible bacterial, sewage and animal waste pollution. Ammonia can
compromise disinfection efficiency, result in nitrite formation in distribution systems, can cause the failure of filters for the removal of manganese, and cause taste and odour problems.

4. pH: One of the main objectives in controlling the pH is to minimize corrosion and incrustation in the distribution system. pH levels of less than 7 may cause severe corrosion of metals in the distribution pipes and elevated levels of certain chemical substances, such as lead, may result. At pH levels above 8, there is a progressive decrease in the efficiency of the chlorine disinfection process. An acceptable pH drinking water is between 6.5 and 8.5. In the absence of a distribution system, the acceptable range of pH may be broader.

5. Hydrogen sulphide: The taste and odour threshold of hydrogen sulphide in water are estimated to be between 0.05 and 0.1 mg/litre. The "rotten egg" odour of hydrogen sulphide is particularly noticeable in some ground waters and improves as water travels in the distribution system, as a result of oxygen depletion and the subsequent reduction of sulphate by bacterial activity. Sulphide is oxidised rapidly to sulphate in well aerated water and hydrogen sulphide level in oxygenated water supplies are normally very low. The presence of hydrogen sulphide in drinking water can be easily detected by the consumer and requires immediate corrective action.

6. Iron: Aerobic ground water may contain ferrous iron at concentrations of up to several mg/litre without discoloration or turbidity in water when directly pumped from the well. On exposure to the atmosphere, however, the ferrous iron oxidises to ferric iron, giving an objectionable reddish - brown colour to the water. Iron also promotes the growth of "iron bacteria", which derive their energy from the oxidation of ferrous iron to ferric iron, and in the process deposit a slimy coating on the pipe. At level above 0.3 mg/litre, iron stains laundry and plum-bing fixtures.

7. Sulfate: The taste threshold concentration of sodium in water depends on the associated anion and the temperature of the solution. At room temperature, the average taste threshold for sodium is about 200 mg/litre.

8. Sulphate: The presence of sulphate in drinking water can cause noticeable taste. Taste impairment varies with the nature of the associated cation. It is generally considered that taste impairment is minimal at levels below 250 mg/litre. It has been found that addition of calcium and magnesium sulphate (but not sodium sulphate) to distilled water improves the taste. Optimal taste was recorded at 270 and 90 mg/litre for the two compounds respectively.

9. Total dissolved solids: Total dissolved solids (TDS) can have an important effect on the taste of drinking water. The palatability of water with a TDS level of less than 600 mg/litre is generally considered to be good. Drinking water becomes increasingly unpleasant at TDS levels greater than 1,200 mg/litre. Water with extremely low concentrations of TDS may be unacceptable because of its flat, insipid taste. The presence of high level of TDS may also be objectionable to consumers owing to excessive scaling in water pipes, heaters, boilers and household appliances. Water with concentrations of TDS below 100 mg/litre is usually acceptable to the consumers.

10. Zinc: Zinc imparts an undesirable astringent taste to water. Tests indicate a taste threshold concentration of 4 mg/litre (as zinc sulphate). Water containing zinc at concentrations of 0.5 mg/litre may appear opalescent and develop a greyish film on boiling, although these effects may also be noticeable at concentrations as low as 3 mg/litre. Drinking water seldom contains zinc at concentrations above 0.1 mg/litre, levels in tapwater can be considerably higher because of the zinc used in plumbing material.

11. Manganese: Manganese concentrations below 0.1 mg/litre are usually acceptable to consumers, this may vary with local circumstances. At levels above 0.1 mg/litre, manganese in water supplies stains sanitary ware and laundry, and causes an undesirable taste in beverages. It may lead to accumulation of deposits in the distribution system. Even at concentration of 0.2 mg/litre, manganese will often form a coating on pipes, which may slough off as a black precipitate.

12. Dissolved oxygen: The dissolved oxygen content of water is influenced by the raw water temperature, composition, treatment and any chemical or biological processes taking place in the distribution system. Depolition of dissolved oxygen in water supplies can encourage microbial reduction of nitrate to nitrite and sulphate to sulphide, giving rise to odour problem. It can also cause an increase in the concentration of ferrous iron in solution. No health-based guideline value has been recommended.

13. Copper: The presence of copper in a water supply may interfere with the intended domestic uses of water. It increases the corrosion of galvanised iron and steel fittings. Staining of laundry and sanitary ware occurs at copper concentrations above 1 mg/litre.

14. Aluminium: The presence of aluminium at concentrations in excess of 0.2 mg/litre often leads to deposits of aluminium hydroxide floc in distribution system and the exacerbation of discoloration of water by iron.

Substances and parameters in drinking water and the reasons for consumer complaints are listed in Table 4.

II. MICROBIOLOGICAL ASPECTS

(a) Bacteriological indicators: Natural and treated waters vary in microbiological quality. Ideally, drinking water from a treated source should not contain any microorganisms known to be pathogenic. It should also be free from bacteria indicative of pollution with sewage. Failure to provide adequate protection, effective treatment and disinfection of drinking water will expose the community to the risk of outbreaks of intestinal and other infectious diseases. Those at greatest risk of water-borne diseases are infants and young children, people who are debilitated or living under insanitary conditions, the sick and the elderly. For them the infective dose is significantly lower than for the healthy population. The potential consequences of microbial contamination are such that its control must always be of paramount importance and must never be compromised.

The primary bacterial indicator recommended for this purpose is the coliform group of organisms as a whole. Supplementary indicator organisms, such as faecal streptococci and sulphite-reducing clostridia, may sometimes be useful in determining the origin of faecal pollution as well as in assessing the efficiency of water treatment processes.

(1) Coliform organisms: The "coliform" organisms include all aerobic and facultative anaerobic gram-negative, non-sporing, motile and non-motile rods capable of fermenting lactose at 35 to 37 deg. C in less than 48 hours. The coliform group includes both faecal and non-faecal organisms. Typical example of the faecal group is E. coli and...

Source: (19)

of the non-faecal group, Klebsiella aerogenes. From a practical point of view it is assumed that all coliforms are of faecal origin unless a non-faecal origin can be proved.

There are several reasons why coliform organisms are chosen as indicators of faecal pollution rather than the water-borne pathogens directly: (1) the coliform organisms are constantly present in great abundance in the human intestine. It is estimated that an average person excretes 200-400 billion of these organisms per day. These organisms are foreign to potable waters, and hence their presence in water is looked upon as evidence of faecal contamination, (2) they are easily detected by culture methods — as small as one bacteria in 100 ml of water, whereas the methods for detecting the pathogenic organisms are complicated and time-consuming, (3) they survive longer than the pathogens, which tend to die out more rapidly than coliform bacilli, (4) the coliform bacilli have greater resistance to the forces of natural purification than the water borne pathogens. If the coliform organisms are present in a water sample, the assumption is the probable presence of intestinal pathogens.

(2) *Fecal streptococci*: Fecal streptococci regularly occur in faeces, but in much smaller numbers than E. coli; in doubtful cases, the finding of faecal streptococci in water is regarded as important confirmatory evidence of recent faecal pollution of water. Streptococci are highly resistant to drying and may be valuable for routine control testing after laying new mains or repairs in distribution systems or for detecting pollution by surface run-off to ground or surface waters.

(3) *Clostridium perfringens*: They also occur regularly in faeces, though generally in much smaller numbers than E. coli. The spores are capable of surviving in water for a longer time than organisms of the coliform group, and usually resist chlorination at the doses normally used in waterworks practice. The presence of spores of *Clostridium perfringens* in a natural water suggests that faecal contamination has occurred, and their presence, in the absence of the coliform group, suggests that faecal contamination occurred at some remote time. Its presence in filtered supplies may indicate deficiency in filtration practice.

The guideline values for bacteriological quality are given in Table 5. It is only a guidance required to ensure bacteriologically safe supplies of drinking water whether piped, unpiped or bottled.

(b) *Virological aspects*: It is recommended that, to be acceptable, drinking-water should be free from any viruses infections for man. Disinfection with 0.5 mg/L of free chlorine residual after contact period of at least 30 minutes at a pH of 8.0 is sufficient to inactivate virus. This free chlorine residual is to be insisted in all disinpected supplies in areas suspected of endemicity of hepatitis A to take care of the safety of the supply from the virus point of view, which incidently takes care of safety from the bacteriologic point of view as well. For other areas 0.2 mg/L of free residual chlorine for half an hour should be insisted. The turbidity condition of 1 NTU or less, must be fulfilled prior to disinfection of water if adequate treatment is to be achieved.

Ozone has been shown to be effective viral disinfectant, preferably for clean water, if residuals of 0.2-0.4 mg/L are maintained for 4 minutes, but it is not possible to maintain an ozone residual in distribution system.

(c) *Biological aspects*: (i) *Protozoa*: Species of protozoa known to have been transmitted by the ingestion of contaminated drinking-water include Entamoeba histolytica, Giardia spp. and rarely, Balantidium coli. These organisms can be introduced into water supply through human or, in some instances, animal faecal contamination. Drinking-water should not contain any pathogenic intestinal

a. Immediate investigative action must be taken if either E. coli or total coliform bacteria are detected. The minimum action in the case of total coliform bacteria is repeat sampling; if these bacteria are detected in the repeat sample, the cause must be determined by immediate further investigation.

b. Although E. coli is the more precise indicator of fecal pollution, the count of thermodurable coliform bacteria is an acceptable alternative. If necessary, proper confirmatory tests must be carried out. Total coliform bacteria are not acceptable indicators of the sanitary quality of rural water supplies, particularly in tropical areas where many bacteria of no sanitary significance occur in almost all untreated supplies.

c. It is recognized that, in the great majority of rural water supplies in developing countries, fecal contamination is widespread. Under these conditions, the national surveillance agency should set medium-term targets for progressive improvement of water supplies.

III. CHEMICAL ASPECTS

The health risk due to toxic chemicals in drinking water differs from that caused by micro-biological contaminants. There are few chemical constituents of water that can lead to acute health problems except through massive accidental contamination of a supply. Moreover, experience shows that, in such incidents the water usually becomes undrinkable owing to unacceptable taste, colour and appearance.

The chemicals selected for the development of guideline value include those considered potentially hazardous to human health, these detected relatively frequently in drinking water and those detected in relatively high concentrations. The problem associated with chemical constituents of drinking water arise primarily from their ability to cause adverse health effects after prolonged periods of exposure; of particular concern are contaminants that have cumulative toxic properties, such as heavy metals — and substances that are carcinogenic.

Health-related chemical constituents

The presence of certain chemicals in excess of prescribed limits may constitute ground for rejection of the water as a source of public water supply. These substances may be inorganic or organic (9).

a. Inorganic constituents: These substances include arsenic, cadmium, chromium, cyanide, fluoride, lead, mercury, nickel, nitrate, selenium etc. The guideline value of these constituents are as shown in Table 6.

1. Arsenic: Arsenic is introduced into water through the dissolution of minerals and ores, from industrial effluents, and from atmospheric deposition; concentrations in ground water in some areas are sometimes elevated as a result of erosion from natural sources. The average daily intake of inorganic arsenic in water is estimated to be similar to that from food. Intake from air is negligible. A provisional guideline value for arsenic in drinking water of 0.01 mg/litre is established.

Source: (19) — Provisional guideline value
2. Cadmium: Cadmium metal is used in the steel industry and in plastics. Cadmium compounds are widely used in batteries. It is released to the environment in wastewater and diffuse pollution caused by contamination from fertilizers and local air pollution. Contamination in drinking water may also be caused by crops grown in the zinc of galvanized pipes and some metal fittings, although levels in drinking water are usually less than 1 μg/l. Absorption of cadmium compound is dependent on the solubility of the compound. Cadmium accumulates primarily in the kidneys and has a long biological half-life in humans of 10-35 years. A guideline value for cadmium is established at 0.3 μg/l (19).

3. Chromium: Chromium is widely distributed in the earth's crust. In general, food appears to be the major source of intake. The absorption of chromium after oral exposure is relatively low and depends on the oxidation state. The guideline value for chromium is 0.05 μg/l, which is considered to be unlikely to give rise to significant health risks.

4. Cyanide: The acute toxicity of cyanide is high. Cyanides can be found in some foods, particularly in some developing countries, and they are usually found in drinking water, primarily as a consequence of industrial contamination. Effects on thyroid and particularly the nervous system were observed in some populations as a consequence of the long-term consumption of inadequately processed cassava containing high levels of cyanide.

5. Fluoride: Fluoride accounts for about 0.3 g/kg of the earth's crust. Inorganic fluoride compounds are used in the production of aluminum and steel. Fluoride is used in the manufacture and use of phosphate fertilizers which contain approximately 0.05% per cent fluoride. Levels of daily exposure of fluoride depend on factors such as the use of fluoride in toothpaste. Fluoride is contained in fish and tea, exposure to tea may be particularly high. In specific areas, other foods and indoor air pollution may contribute considerably to total intake.

6. Lead: Lead is present in tapwater to some extent as a result of its dissolution from natural sources, but primarily from household plumbing systems containing lead in pipes, solder, fittings or the service connections to homes. The amount of lead dissolved from the plumbing system depends on several factors, including pH, temperature, water hardness and standing time of the water, with soft, acidic water being the most conducive to the release of lead. Plaque-like transfer of lead occurs in humans as early as twelfth week of gestation and continues throughout development. Young children absorb 4-5 times as much lead as adults, and the biological half-life may be considerably longer in children than in adults. Lead is a general toxicant that accumulates in the skeleton. Infants, children up to six years of age, and pregnant women are most susceptible to its adverse health effects. Lead also interferes with calcium metabolism, both directly and by interfering with vitamin D metabolism. Lead is toxic to both central and peripheral nervous system, inducing sub-encephalopathic neuropsychological and behavioural effects. Renal tumours have been induced in experimental animals disposed to high levels of lead in the diet and it is grouped in Group 2B (possible human carcinogen). The health-based guideline value of lead is 0.01 mg/l.

Lead is exceptional in that most lead in drinking water arises from plumbing in buildings and the sanitary system. The compound constitutes principally of removing plumbing and fittings containing lead. This requires much time and money, and it is recognized that not all water will meet the guideline immediately. Measures to control corrosion should also be implemented.

7. Mercury: Mercury is present in inorganic form in surface and ground water at concentrations usually less than 0.5 μg/l. The kidney is the main target organ for inorganic mercury, whereas methyl mercury affects mainly the central nervous system. The guideline value for total mercury is 0.006 mg/l.

8. Nitrate and nitrite: Nitrate and nitrite are naturally occurring ions that are part of the nitrogen cycle. Naturally occurring nitrate ion level in surface and ground water are generally a few milligrams per liter. Many ground waters, as an increase of nitrate level has been observed owing to the increase of nitrate intake may result from the use of fluoride toothpaste.

Exposure to fluoride from drinking water depends greatly on natural circumstances. Levels in raw water are normally below 1.5 mg/l, but ground water may contain about 10 mg/l in areas rich in fluoride – containing minerals. High fluoride levels, above 5 mg/l, have been found in several countries (e.g., China, India and Thailand). Such high levels have at times led to dental or skeletal fluorosis. Fluoride is sometimes added to drinking water to prevent dental caries. Soluble fluorides are readily absorbed in the gastrointestinal tract after intake in drinking water. The fluoride guideline value is 1.5 mg/l. In setting national standards for fluoride, it is particularly important to consider climatic conditions, volume of water intake and intake of fluoride from other sources (e.g., food and air).

9. Selenium: Selenium levels in drinking water vary greatly in different geographical areas, and are usually much less than the guideline value of 0.01 mg/l. Food stuffs are the principal source, and the level depends on geographical area of production. Selenium is an essential element for humans and forms an integral part of the enzyme glutathione peroxidase. Most selenium compounds are water soluble. In humans, the toxicity of long-term exposure is manifested in nails, hair and liver.
b. Organic constituents: The guideline values of some of the organic chemical constituents in water are as shown in Table 7.

Source: (19)

Polyaromatic aromatic hydrocarbons: A large number of polynuclear aromatic hydrocarbons (PAHs) from a variety of combustion and pyrolysis sources have been identified in the environment. The main source of human exposure to PAHs is food, with drinking water contributing only minor amounts.

Little information is available on the oral toxicity of PAHs, especially after long-term exposure. Benzo(a)pyrene, which constitutes a minor fraction of total PAHs, has been found to be carcinogenic in mice by the oral route of administration. Some PAH compounds have been found to be carcinogenic by non-oral routes. Benzo(a)pyrene has been found to be mutagenic in a number of in vitro and in vivo assays.

The following recommendations are made for the PAH group:

- Because of the close association of PAH with suspended solids, the application of treatment, when necessary to achieve the recommended level of turbidity will ensure that PAH levels are reduced to a minimum.
- Contamination of water with PAH should not occur during water treatment or distribution. Therefore, the use of coal-tar-based and similar materials for pipe-lining and coatings on storage tanks should be discontinued.
- In situations where contamination of drinking water by PAH has occurred, the specific compounds present and the source of the contamination should be identified, as the carcinogenic potential of PAH compounds varies.

Pesticides: The pesticides that are of importance are connection with water quality include chlorinated hydrocarbons and their derivatives, persistent herbicides, rod insecticides, pesticides that are easily leached out from the soil, and pesticides that are systematically added to water supplies for disease vector control. The recommended guideline value (Table 8) are set at a level to protect human health.

Source: (19)  P - Provisional value

Drinking water consumption and body weight: The average daily per capita consumption of drinking water is usually found to be around 2 litres, but there are considerable variations between individuals as water intake is likely to vary with climate, physical activity and culture, e.g., at temperatures above 25°C, there is a sharp rise in fluid intake, largely to meet the demands of an increased sweat rate. In developing the guideline values for potentially hazardous chemicals, a daily per capita consumption of 2 litres by a person weighing 60 kg was generally assumed. However, such an assumption may underestimate the consumption of water per unit weight, and this exposure, for those living in hot climates as well as for infants and children, who consume more fluid per unit weight than adults. Where it was judged that this segment of the population was at a particularly high risk from exposure to certain chemicals, the guideline value was derived on the basis of a 10 kg child consuming 1 litre water per day or a 5 kg infant consuming 0.75 litre water per day.

Health-risk assessment: For most kinds of toxicity, it is generally believed that there is a dose below which no adverse effects will occur. For chemicals that give rise to such toxic effects, a tolerable daily intake (TDI) can be derived. Tolerable daily intake (TDI): The TDI is an estimate of the amount of a substance in food or drinking water, expressed on a body weight basis (mg/kg or μg/kg of body weight), that can be ingested daily over a lifetime without appreciable health risk (19).

Acceptable daily intake (ADI) is established for food additives and pesticide residues that occur in food for necessary technological purposes or plant protection reasons. For chemical contaminants, which usually have no intended function in drinking water the term TDI is seen as more appropriate than ADI, as it signifies permissibility rather than acceptability.

No-observed-adverse-effect level (NOAEL): The NOAEL is defined as the highest dose or concentration of a chemical in a single study, found by experiment or observation, that causes no detectable adverse health effect (19). Whenever possible, the NOAEL is based on long-term studies, preferably of Ingestion in drinking water.

Least-observed-adverse-effect level (LOAEL): LOAEL:
is the lowest observed dose or concentration of a substance at which there is a detectable adverse health effect (19). When NOAEL is used instead of NOAEL, an additional uncertainty factor (UF) is normally used.

Uncertainty factors (UF): The application of uncertainty factors has been widely used in the derivation of ADI for food additives, pesticides and environmental contaminants. The derivation of these factors requires expert judgement and a careful sifting of the available scientific evidence.

In the derivation of the WHO drinking water quality guideline values, uncertainty factors were applied to the lowest NOAEL or LOAEL for the response considered to be most biologically significant and were determined by consensus among a group of experts using the approach outlined below:

<table>
<thead>
<tr>
<th>Source of uncertainty</th>
<th>Factor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interspecies variation (animal to humans)</td>
<td>1 – 10</td>
</tr>
<tr>
<td>Intraspecies variation (individual variation)</td>
<td>1 – 10</td>
</tr>
<tr>
<td>Adequacy of studies or database</td>
<td>1 – 10</td>
</tr>
<tr>
<td>Nature and severity of effect</td>
<td>1 – 10</td>
</tr>
</tbody>
</table>

The total uncertainty factor should not exceed 10,000. If the risk assessment would lead to a higher uncertainty factor, then the resulting TDI would be so imprecise as to lack meaning. For substances for which uncertainty factors were greater than 1000, guideline values are designated as provisional in order to emphasize the high level of uncertainty inherent in these values (19).

Derivation of guideline value using a TDI approach: TDI can be calculated by following formula.

\[
TDI = \frac{NOAEL \text{ or LOAEL}}{UF}
\]

The guideline value (GV) is then derived from the TDI as follows:

\[
GV = \frac{TDI \times bw \times P}{C}
\]

Where
- \( bw \) = body weight (60 kg for adult, 10 kg for children, 5 kg for infants)
- \( P \) = fraction of the TDI allocated to drinking water
- \( C \) = daily drinking water consumption (2 litres for adults, 1 litre for children and 0.75 litre for infants)

IV. RADIOLOGICAL ASPECTS

The effects of radiation exposure are called "stochastic" if they become manifest in the exposed individual, and "hereditary" if they affect the descendants. Malignant disease is the most important delayed stochastic effect (30). For some stochastic effects such as carcinogenesis, the probability of an effect occurring, rather than its severity, is regarded as a function of dose without a threshold (stochastic effect). Whereas for other stochastic effects the severity of the effect varies with the dose (non-stochastic effects); a threshold may therefore exist for such effects. The aim of radiation protection is to prevent harmful non-stochastic effects and to reduce the probability of stochastic effects to a level deemed acceptable.

Radioactivity in drinking water should not only be kept within safe limits; it should also, within those limits, be kept as low as is reasonably possible. The guideline values recommended take account of both naturally occurring radioactivity and any radioactive material that may reach the water source as a result of man's activities. From a radiological point of view, they represent a value below which water can be considered potable without any further radiological examination.

The activity of a radioactive material is the number of nuclear disintegrations per unit of time. The unit of activity is a becquerel (Bq); 1 Bq = 1 disintegration per second. Formerly, the unit of activity was curie (Ci).

The proposed guideline values are:
- gross alpha activity: 0.5 Bq/L
- gross beta activity: 1.0 Bq/L

SURVEILLANCE OF DRINKING WATER QUALITY

The activities that ideally should be included in the surveillance function are:

- approval of new sources (including private-owned supplies)
- watershed protection
- approval of the construction and operating procedures of waterworks, including:
  - disinfection of the plant and of the distribution system after repair or interruption of supply
  - periodic flushing programmes and cleaning of water storage facilities
  - certification of operators
  - regulation of chemical substances used in water treatment
  - cross-connection control, back-flow prevention and leak detection control
- sanitary surveys
- monitoring programmes, including provision for central and regional analytical laboratory services
- development of codes of practice for well construction, pump installation and plumbing
- inspection quality control in bottled water and ice manufacturing operations

Surveillance of drinking water is essentially a health measure. It is intended to protect the public from waterborne diseases. The elements of a surveillance programme are:

1. Sanitary survey
   - Sanitary survey is an on-the-spot inspection and evaluation by a qualified person of the entire water supply system. The purpose of the survey is detection and correction of faults and deficiencies. A sanitary survey is essential for adequate interpretation of laboratory results.

2. Sampling
   - Sampling of water should be done with the thoroughness of a surgical operation, with the observation of similar aseptic precautions, for upon it depends the results of analysis. It should be carried out by competent and trained personnel in strict accordance with the methods and frequency of sampling prescribed in the WHO guidelines for drinking-water quality or the ICMR 'Manual of Standard of
3. Bacteriological surveillance

The tests usually employed in water bacteriology are presumptive coliform tests, tests for the detection of fecal streptococci and *Clostridium perfringens* and colony count. A complete bacteriological examination consists of all these tests.

(1) PRESUMPTIVE CULTURE TEST

(i) Multiple tube method: This test is based on estimating the most probable number (MPN) of coliform organisms in 100 ml of water. The test is carried out by inoculating measured quantities of the sample water (0.1, 1.0, 10, 50 ml) into tubes of McConkey’s Lactose Bile Salt Broth with bromcresol purple as an indicator. The tubes are incubated for 48 hours. From the number of tubes showing acid and gas, an estimate of the MPN of coliform organisms in 100 ml of the sample water can be obtained from statistical tables. This result is known as “presumptive coliform count”, the presumptive being each tube showing fermentation, contains coliform organisms. The reaction may occasionally be due to the presence of some other organisms or combination of organisms.

Confirmation tests: The next step is to confirm the presence of coliform organisms in each tube showing a presumptive positive reaction. Such confirmation is not generally required in case of unchlorinated water, but is required in case of chlorinated water. Confirmation is done by subculturing each presumptive positive tube in 5 tubes of brilliant green bve broth, one of which is incubated at 37 deg C for up to 48 hours for confirmation of the presence of coliform organisms, and the other incubated at 44 deg C and inspected after 6 and 24 hours to decide whether or not *E. coli* is present. *E. coli* is almost the only coliform organism which is capable of producing gas from lactose at 44 deg C.

Further confirmation of the presence of *E. coli*, if desired, can be obtained by testing for indol production at 44 deg C.

(ii) Membrane filtration technique: In some countries membrane filter technique is used as a standard procedure to test for the presence of coliform organisms. A measured volume of the sample is filtered through a membrane specially made of cellulose ester. All the bacteria present in water are retained on the surface of the membrane and by inoculating the membrane face upwards on suitable media and at appropriate temperature, it is possible to count the colonies and obtain results within 20 hours as compared to 72–96 hours required for the usual multiple tube technique.

(2) THE DETECTION OF Faecal Streptococci AND *Clostridium perfringens*

The presence of fecal streptococci and *Clostridium perfringens* provides useful confirmatory evidence of the faecal pollution of water in doubtful cases.

(3) COLONY COUNT

Colony counts on nutrient agar at 37 deg C and 22 deg C are frequently used in the bacteriological examination of water. Colony counts provide an estimate of the general bacterial purity of water. A single count of little value, but counts from the same source at frequent intervals may be of considerable value. A sudden increase in the colony count may give the earliest indication of contamination. The recommended plate counts are:

- Water at the point of consumption
  - Plate count after 2 days at 37 deg C
    - (i) Disinfected: 0
    - (ii) Not-disinfected: 10
  - Plate count after 3 days at 37 deg C
    - (i) Disinfected: 20
    - (ii) Not-disinfected: 100

Recent studies indicate that a bacterial plate count on yeast extract agar after incubation at 22 deg C for 7 days might serve as the best general purpose indicator of microbiological quality because in the absence of chlorine residual, the number of bacteria growing at 22 deg C after 7 days incubation can increase enormously (22).

4. Biological examination

Water may contain microscopic organisms such as algae, fungi, yeast, protozoa, rotifers, crustaceans, minute worms, etc. These organisms are collectively called ‘plankton’. The plankton organisms produce objectionable tastes and odours in water. They are an important pollution. The degree of pollution is assessed qualitatively and quantitatively by noting the type and number of organisms prevailing in water.

5. Chemical surveillance

Chemical surveillance of drinking water is assuming greater importance in view of industrial and agricultural pollutants finding their way into raw water sources. Tests for pH, colour, turbidity, chlorides, ammonia, chlorine demand and residual chlorine are the basic tests. Regular measurement of chlorine residuals in supply may in part replace bacteriological surveillance. Tests for iron and manganese are required when these substances are present in the raw water in sufficient amount to influence water treatment. Complete chemical analysis would also include analysis for toxic metals, pesticides, persistent organic chemicals and radioactivity.

**HARDNESS OF WATER**

Hardness may be defined as the soap destroying power of water. The consumer considers water hard if large amounts of soap are required to produce lather. The hardness in water is caused mainly by four dissolved compounds produced in limestones (1) Calcium carbonate (2) Magnesium bicarbonate (3) Calcium sulphate, and (4) Magnesium sulphate. The presence of any one of these compounds is an indication of pollution which are of less importance. Chlorides and nitrates of calcium and magnesium can also cause hardness but they occur generally in small amounts. Iron, manganese and aluminium compounds also cause hardness, but as they generally are present in such small amounts, it is customary not to consider them in connection with hardness.

Hardness is classified as carbonate and non-carbonate. The carbonate hardness which was formerly designated as “temporary” hardness is due to the presence of calcium and magnesium bicarbonates. The non-carbonate hardness, formerly designated as “permanent” hardness, is due to calcium and magnesium sulphates, chlorides and nitrates.

Hardness in water is expressed in terms of “mills-equivalents per litre (mEq/L)”. One mEq/L of hardness-producing ion is equal to 50 mg CaCO₃ (50ppm) in one litre of water (23). The terms soft and hard water are used when the levels of hardness are as given in Table 9.
TABLE 9
Classification of hardness in water

<table>
<thead>
<tr>
<th>Description</th>
<th>Level of hardness in ppm (mg/L)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) Soft water</td>
<td>Less than 1 (&lt;50 mg/L)</td>
</tr>
<tr>
<td>(b) Moderately hard</td>
<td>1-3 (50-150 mg/L)</td>
</tr>
<tr>
<td>(c) Hard water</td>
<td>≥4 (150-300 mg/L)</td>
</tr>
<tr>
<td>(d) Very hard water</td>
<td>over 5 (&gt; 300 mg/L)</td>
</tr>
</tbody>
</table>

Drinking water should be moderately hard. Softening of water is recommended when the hardness exceeds 3 mg/L (150 mg per liter).

DISADVANTAGES OF HARDNESS
Hardness in water presents several disadvantages both to the domestic and industrial consumer. These may be stated as follows: (1) hardness in water consumes more soap and detergents (2) when hard water is heated, the carbonates are precipitated and bring about furring or scaling of boilers. This leads to great fuel consumption, loss of efficiency and may sometimes cause boiler explosions (3) hard water adversely affects cooking; food cooked in soft water retains its natural colour and appearance (4) fabrics washed with soap in hard water do not have a long life (5) there are many industrial processes in which hard water is unsuited and gives rise to economic losses (6) hardness shortens the life of pipes and fixtures.

SPECIAL TREATMENT

(a) Removal of hardness

The methods of removal of hardness are briefly stated as below:

Temporary hardness
(a) Boiling
(b) Addition of lime
(c) Addition of sodium carbonate
(d) Permutit process.

Permanent hardness
(a) Addition of sodium carbonate
(b) Base exchange process.

1. BOILING

Boiling removes the temporary hardness by expelling carbon dioxide. and precipitating the insoluble calcium carbonate. It is an expensive method to soften water on a large scale.

Calcium carbonate

Ca(HCO₃)₂ → CaCO₃ + H₂O + CO₂

2. ADDITION OF LIME

Lime softening not only reduces total hardness but also accomplishes magnesium reduction. Lime absorbs the carbon dioxide, and precipitates the insoluble calcium carbonate. In the Clark's method of softening water, one ounce of quick lime is added to every 100 gallons of water for each degree (14.25 ppm) of hardness.

Calcium hydroxide

Ca(OH)₂ + Ca(HCO₃)₂ → 2CaCO₃ + 2H₂O

3. ADDITION OF SODIUM CARBONATE

Sodium carbonate (soda ash) removes both temporary and permanent hardness, as shown below:

(i) Na₂CO₃ + Ca(HCO₃)₂ → 2NaHCO₃ + CaCO₃

(ii) CaSO₄ + Na₂CO₃ → CaCO₃ + Na₂SO₄

4. BASE EXCHANGE PROCESS

In the treatment of large water supplies, the permexit process is used. Sodium permexit is a complex compound of sodium, aluminium and silica (Na₆Al₂Si₅O₁₄(OH)₂). It has the property of exchanging the sodium cation for the calcium and magnesium ions in the water. When hard water is passed through the permexit the calcium and magnesium ions are entirely removed by base exchange and the sodium permexit is finally converted into calcium and magnesium permexit. By this process, water can be softened to zero hardness. Since water of zero hardness is corrosive, a part of the raw water is mixed with the softened water to secure the desired hardness. After permexit has been used for some time, it loses its effectiveness but it may be regenerated by treating with concentrated solution of sodium chloride or being cleaned and washing away the soluble calcium and magnesium chloride formed. Permexit process removes both temporary and permanent hardness.

Water hardness and cardiovascular diseases

Reports from several countries have shown an inverse statistical association between the hardness of drinking water and the death rate from cardiovascular diseases. Areas supplied with soft drinking water showed a significantly higher prevalence of either arteriosclerotic heart disease, or degenerative heart disease, hypertension, sudden deaths of cardiovascular origin, or a combination of these. The evidence is based solely on circumstantial evidence and statistical association. Further studies are in progress to establish a possible connection between certain water characteristics and the development of cardiovascular diseases (24).

(b) Fluoridation of water

Fluoride is one of the constituents naturally present in water supplies. In fact, the main source of fluoride is drinking water. Deficiency of fluoride in drinking water is associated with dental caries, and excess with dental and skeletal fluorosis. Leading workers in India regard fluoride in concentration of 0.5 to 0.8 ppm in drinking water as optimum (a concentration of 1 ppm is regarded as optimum in temperate climates because the consumption of water is low). The term "fluoridation" has been given to the process of supplementing the natural fluoride content of potable waters to the point of optimum concentration. The WHO in 1969 recommended fluoridation, of community water supplies in areas where the total intake of fluorides by the population is below the optimum levels for protection against dental caries. Fluoridation is now an accepted public health procedure in many developed countries (25).

(c) Defluoridation

In some geographic areas, water may contain a high level of fluorides. In such communities, water is defluoridated by phosphate to reduce fluorides to optimum levels.

SELECTION OF SOURCE OF WATER

In selecting a source, attention must be given to possible future developments that may influence the continued suitability of the source. Other considerations include (a) Quantity (source capacity) : The quantity of water should be sufficient to meet continuing water demands, taking into account daily and seasonal variations and projected growth in the size of the community being served. (b) Quality : The quality of raw water should be such that, with appropriate
treatments, it meets the drinking water standards. (c) Protection: The watershed must be protected from pollution caused by agricultural run-off. (d) Feasibility: The source should be available at a reasonable cost (e) Treatability: The raw water should be treated adequately under locally prevailing conditions.

Potential new sources should be examined in the field by qualified and experienced sanitary surveyors and physical, bacteriological and chemical analysis should be carried out for a period covering seasonal variations prior to final selection of the source. Such information is essential in order to define appropriate water treatment requirements and necessary pollution control measures to protect raw water resources. It is preferable to choose the source that requires the least treatment. The source should be protected from contaminants emanating from septic tanks, sewers, cesspools, village water and flooding and from contamination by vermin. Maintaining adequate residual chlorine levels in the distribution system is the most reliable indicator of protection against contamination resulting from cross-connection, back siphonage, leaks etc.

DISTRIBUTION OF WATER

There are two main systems of water distribution, the intermittent supply and the continuous supply. In the intermittent system, water is delivered only during fixed hours. The disadvantages of the intermittent system are: (1) the pipes may be empty during times of emergency (2) people need to store water in containers which may not be clean always. The safe water is likely to be rendered unsafe through improper storage (3) when the pipes are empty, there is negative pressure and by what is known as back siphoning, bacteria and foul gases may be sucked in through leaky joints. A number of recorded outbreaks of typhoid and of relapsing fever, among other diseases, have been traced back to the contamination of water in the intermittent piped water supplies. Flowing water available 24 hours is therefore desirable, although it may entail some wastage of water through misuse. The supply of water in most cities in India is intermittent. A WHO Expert Committee (1965) strongly recommended that intermittent and low pressure service should be avoided (26). DUAL WATER SUPPLY: In Kolkata, there was a dual water supply system, i.e., one set of pipes supplying filtered water for personal use and the other set supplying unfiltered water for flushing toilets, washing roads and other civic purposes. The greatest drawback of the dual system is that people may mistake one for the other through ignorance. The WHO Expert Committee (1965) strongly disapproved of the practice of supplying two kinds of water (26). The possibility of cross-contamination constitutes a serious health hazard.

SWIMMING POOL SANITATION

Swimming pool water is exposed to (1) faecal contamination, (2)體 warts, and (3) respiratory infections. The health hazards associated with swimming pools are:

1. fungal and viral infections of the skin. This includes Epidermophyton and Trichophyton species which produce "athlete's foot." The papilloma virus is the inciting agent of "plantar warts."
2. infections of the eye, ear, nose and throat (3) infections of the upper respiratory tract, (4) intestinal infections, and (5) accidents.

SANITATION MEASURES

(1) Recommended area: The recommended area is 2.2 sq.m. (24 sq.ft.) per swimmer (27). (2) Surveillance: Rules and regulations governing the use of the pool should be posted in a conspicuous place for the information of the users. These are: (a) Persons suffering from skin diseases, sores, cold, nasal or ear discharge or any other communicable disease should not be allowed into the swimming pool. (b) All bathers are strictly instructed to empty the bladder and if necessary use the toilet. (c) A cleansing shower bath in the nude with soap and water is required before entering the pool. (d) Spitting, spouting of water, blowing the nose, etc. are prohibited. (e) The environment of the swimming pool including the shower rooms, walk ways and pool decks should receive proper disinfection to destroy bacterial, viral and fungal agents. (2) Filtration of water: Swimming pools are equipped with rapid sand filters. The filtering is continuous such that all the water is filtered in less than 6 hours. Part of the water, up to 15 per cent, should be replaced by fresh water every day. The function of water replacement is to remove solute consisting of ammonia, albuminoid, organic and nitrate nitrogen derived from the bathers. These solutes have the capacity to reduce the bacteriological activity of chlorine. (3) Chlorination: Chlorination is the most widely used method of pool disinfection. Various workers have stated that a continuous maintenance of 1.0 mg/litre (1 ppm) of free chlorine residual provides adequate protection against bacterial and viral agents (28). The pH of water is kept between 7.4-7.8. (4) Bacteriological quality: The bacteriological quality of water should reach, as nearly as possible, the standards prescribed for drinking water. National Water Supply and Sanitation Programme

The National Water Supply and Sanitation Programme was launched in 1954 by the Govt. of India as part of the Health Plan, to assist the States to provide adequate water supply and sanitation facilities in the entire country. Provision has been made in the successive 5-year Plans to improve the water supply (29). For further details see chapter 7 page 476.

Health education

The provision of merely good water supply does not in itself secure freedom from water-borne diseases. People must recognize safe water as a "felt" health need and give up their old, unhygienic habits of polluting water supplies. In these circumstances, health education emerges as an important weapon in creating among people a desire for higher standards of life.

APPENDIX I

HORROCK’S APPARATUS

Horrack’s water testing apparatus is designed to find out the dose of bleaching powder required for disinfection of water.
CONTENTS
1. 6 white cups (200 ml capacity each)
2. 1 black cup with a circular mark on the inside
3. 2 metal spoons (each holds 2g of bleaching powder when filled level with the brim)
4. 7 glass stirring rods
5. 1 special pipette
6. 2 droppers
7. Starch-iodide indicator solution
8. Instruction folder.

PROCEDURE
1. Take one level spoonful (2 g) of bleaching powder in the black cup and make it into a thin paste with a little water. Add more water to the paste and make up the volume up to the circular mark with vigorous stirring. Allow to settle. This is the stock solution.
2. Fill the 6 white cups with water to be tested, up to about a cm below the brim.
3. With the special pipette provide one drop of the stock solution to the 1st cup, 2 drops to the 2nd cup, 3 drops to the 3rd cup, and so on.
4. Stir the water in each cup using a separate rod.
5. Wait for half an hour for the action of chlorine.
6. Add 3 drops of starch-iodide indicator to each of the white cups and stir again. Development of blue colour indicates the presence of free residual chlorine.
7. Note the first cup which shows distinct blue colour. Supposing the 3rd cup shows blue colour, then 3 spoonfuls of bleaching powder would be required to decolorize 453 litres of water.

APPENDIX II

SAMPLING
1. Samples for physical and chemical examination
Samples for physical and chemical examination should be collected in clean glass stoppered bottles made of neutral glass, of capacity not less than 2 litres. Stoppered glass bottles technically known as “Winchester Quarti bottles” are suitable. Before collecting the sample rinse the bottle well three times with the water, filling it each time about 1/3 full. Then fill it with the water, tie the stopper tightly down, with a piece of cloth over it and seal the string.

2. Samples for bacteriological examination
Samples for bacteriological examination should be collected in clean sterilized bottles made of neutral glass, of capacity 200-250 ml and provided with a ground glass stopper having an o-erlining rim. The stopper must be relaxed by an inter-twining strip of paper to prevent breakage of the bottle during sterilization or jamming of the stopper. The stopper and the neck of the bottle should be protected by a paper or parchment cover. If the water to be sampled contains, or is likely to contain chlorine, a small quantity of sodium thiosulphate (0.1 ml of 3.0 per cent solution or a small crystal of the salt) should be added to the bottle before sterilization. Sterile sampling bottles should be obtained from the laboratory which is to carry out the analysis. The sampling bottle should not be opened until the moment at which it is to be filled.

(1) COLLECTION OF THE SAMPLE FROM A TAP
When the sample is to be taken from a tap in regular use, the tap should be opened fully, and the water run to waste at least for 2 minutes in order to flush the interior of the nozzle and to displace the sterilized string, and the service pipe. In the case of samples to be collected from taps which are not in regular use, the tap should be sterilized by heating it either with a blow lamp or with an ignited piece of cotton soaked in methylated spirit, until it is unbeatable hot to the touch. Then the tap should be cooled by allowing the water to run to waste before the sample is collected.

The bottle should be held near the base with one hand and the stopper and paper cover over it removed together and held in the fingers. The sample bottle should be filled from a gentle stream of water from the tap, avoiding splashing. The collection of samples from taps which are leaking, should be avoided because the water might run down the outside of the tap and enter the bottle causing contamination. If this cannot be avoided, special precautions should be taken to clean the outside of the tap and to flame it sufficiently to ensure sterility.

(2) COLLECTION OF SAMPLES FROM RIVERS, LAKES, RESERVOIRS, WELLS, ETC
Samples from rivers and streams should not be taken too near the bank or too far away from the point of draw off. For collecting samples directly from rivers, lakes, tanks, wells etc., a bottle with a string attached to the neck which is fully wrapped in paper and sterilized should be used. Before taking the sample, the paper cover should be removed, taking care not to allow the sides of the bottle to come in contact with anything. Another long clean string should be tied to the end of the sterilized string, and the bottle lowered into the water and allowed to fill up. The bottle should then be raised and the stopper with cover replaced.

Another method of collecting samples from rivers or reservoirs is to hold the bottle by the bottom and plunge its neck down-wards below the surface of the water. The bottle is then turned until the neck points slightly upwards, the mouth being directed towards the current. If no current exists, as in a reservoir, a current should be artificially created by pushing the bottle horizontally forward in a direction away from the hand. When full, the bottle is raised rapidly above the surface and the stopper replaced.

If a sample is to be taken from a well fitted with a pump, the water should be pumped to waste for about 5 minutes and the sample collected from the pump delivery or from a tap on the discharge.

(3) TRANSPORT AND STORAGE OF SAMPLES
The bacteriological examination of the sample should be commenced as soon as possible after collection. Where this is not feasible, the sample should be kept in ice until it is taken for analysis. All such iced samples should be taken for analysis within 48 hours after collection. Samples not preserved in this manner should not be accepted for bacteriological examination. Certain particulars regarding the date and time of collection and despatch, source of water, particulars of recent rainfall and findings of the sanitary survey should also be supplied with the sample.

APPENDIX IV

WATER CONSERVATION

Draining trend of rainfall and rapid urbanization with industrialization has created increasing demand for water. Groundwater shortage is already causing problems in several areas and available resources like rivers, ponds, lakes are shrinking, causing more & more pressure on sub-soil water resources. Already, the role of water extraction is exceeding the replenishment that takes place by natural processes – mainly recharge due to rainfall. This is causing alarming fall in sub-surface water levels which is going down in and around several cities. Development of agriculture dependents on tube wells has further worsened the situation. The underground water resources, therefore, urgently need conservation. The term conservation implies both, protection of water resources, and further building up the precious water reserves.

Conservation of water resources requires:

(a) PREVENTION OF WASTAGE: Wide spread awareness needs to be developed among people about economical use of water. It has to be propagated that people should make an effort not to waste water, and help in reducing consumption of the invaluable water resources. Efficient water management can substantially reduce total water requirement of communities. Domestic consumption of water can be reduced by individuals, by cultivating better habits in kitchen and bathroom use, to avoid free running of water.

(b) WATER HARVESTING: Simple innovative ideas like water harvesting are extremely important to preserve and build up underground water reserves in urban and semi-urban areas, where considerable water is drawn out by tube wells for domestic consumption. Vast quantity of rainwater is normally discharged in to drains. This rainwater can be easily added to the underground reserves by diversion of rainwater from rooftops and courtyards into soaking pits or trenches, instead of drains. It is also viable to clean and filter this water and divert it into existing tube wells or wells.

Various economic designs are suggested by agencies like Central Ground Water Board (CGWB), UNICEF etc. Suitably large pit is filled in layers with big stones, followed by gravel and sand. Collected rainwater from rooftops is brought into the pit by PVC pipes. The rainwater filtered through these layers, then travels by a PVC pipe connecting bottom of the pit into the nearby well or tube well.

References

The immediate environment of man comprises of air on which depends all form of life. Apart from supplying the life-giving oxygen, air and atmospheric conditions serve several functions. The human body is cooled by the air contact; the special senses of hearing and smell function through air- transmitted stimuli; disease agents may be conveyed by air. Pollution of air by dust, smoke, toxic gases and chemical vapours has resulted in sickness and death. Many times the air has been considered a major factor in the concept of air environment. Human beings need a continuous supply of air to exist. The requirement for air is relatively constant (about 10–20 m3 per day).

Composition
Air is a mechanical mixture of gases. The normal composition of external air by volume is approximately as follows: Nitrogen – 78.1 per cent; Oxygen – 20.93 per cent; Carbon dioxide – 0.03 per cent. The balance is made up of other gases which occur in traces, e.g., argon, neon, krypton, xenon and helium. In addition to these gases, air also contains water vapour, traces of ammonia and suspended matter such as dust, bacteria, spores and vegetable debris.

Air is rendered impure by (1) Respiration of men and animals (2) Combustion of coal, gas, oil, etc. (3) Decomposition of organic matter and (4) Trade, traffic and manufacturing processes which give off dust, fumes, vapours and gases. Under ordinary conditions, the composition of outdoor air is remarkably constant. This is brought about by certain self-cleansing mechanisms which operate in nature. (1) Wind: Wind dilutes and disperses away the impurities by its movement. Because of wind movement, impurities do not accumulate in any one place; (2) Sunlight: The atmospheric temperature and sunlight play their own part by oxidation of impurities, and killing bacteria; (3) Rain: It cleanses the atmosphere by removing the suspended and gaseous impurities; (4) Plant life: The green plants utilize the carbon dioxide and generate oxygen; this process is reversed during the night time. When the rate of pollution becomes too high or when the cleansing process becomes ineffective, it constitutes a health hazard.

The air of occupied room
Human occupancy and activity vitiate air in occupied rooms and give a sense of discomfort to the occupants. The changes in air that take place in confined places are both chemical and physical. (a) CHEMICAL CHANGES: The air becomes progressively contaminated by carbon dioxide and the oxygen content decreases due to metabolic processes. An average person at rest gives off 0.7 c.f. of carbon dioxide per hour; this may increase up to 2 c.f. during physical activity. In a mixed gathering comprising all age groups, the per capita output of carbon dioxide is taken as 0.6 c.f. per hour, (b) PHYSICAL CHANGES: The most important changes that occur due to human occupancy are the physical changes. These are (i) Rise in temperature: The indoor temperature tends to rise as a result of the emanation of body heat. A man at rest gives off approximately 400 Btu per hour. One Btu (British Thermal Unit) is the quantity of heat required to raise the temperature of one pound of water by 1 deg. F. Under conditions of physical exertion, the heat output may go up to 4,000 Btu. (ii) Increase of humidity: There is an increase in the relative humidity due to moisture evaporated from the skin and lungs. The expired air contains about 6 per cent of water vapour. An adult person at rest releases an average 700 gms. of water vapour per 24 hours in the form of perspiration. It has been calculated that a human being releases 18.4 gms of water vapour per hour when sleeping and upto 175 gms of water vapour when engaged in really vigorous exercise (i–iii). Decrease in air movement: In crowded places, the natural movement of air is impeded. (iv) Body odours: Unpleasant odours arise from foul breath, perspiration, bad oral hygiene, dirty clothes and other sources. The production of body odours depends upon the social states, age and personal hygiene of the people. (v) Bacterial pollution: The exhaled air contains microorganisms in suspension. These are principally saprophytic bacteria and may include pathogenic bacteria. These organisms are discharged into the air during conversation, coughing, sneezing and loud talking.

Unless the vitiated air is replaced by fresh air, it may adversely affect the comfort, health and efficiency of the occupants. It is known that a feeling of suffocation or discomfort is experienced by the occupants in insufficiently ventilated rooms and also complains of headache, drowsiness and inability to concentrate. There is also the risk of droplet infection and lowered resistance to disease (on prolonged exposure).

Discomfort
Discomfort is a subjective sensation which people experience in ill-ventilated and crowded rooms. For a long time it was believed to be due to increased carbon dioxide and decreased oxygen, resulting from respiration. People have shown that the oxygen content may be reduced to 18 per cent and the carbon dioxide content may be raised to over 5 per cent, without adverse effects, provided the temperature and humidity are kept satisfactory. In the 'Black Hole' of Kolotia, 146 prisoners were imprisoned in a room, 18 x 14 x 19 of whom only 23 survived. There were two small windows which were adequate to supply all the oxygen needs of even ten only 23 survived. It was concluded that the deaths were due to changes in the physical condition of the air, leading to 'heat retention'. It is now established that the causes of discomfort are not due to chemical changes but physical changes. These are temperature, humidity, air...
movement and heat radiation. These factors determine the "cooling power" of the air with respect to the human body. It has been so well said by Professor Lee that "The problems of ventilation are physical, not chemical; cutaneous not respiratory".

Indices of thermal comfort

Thermal comfort is a complex entity. Much work was done in the past to determine what constitutes "thermal comfort". Several indices have been put forward from time to time to express thermal comfort and heat stress. These are as follows: (1) AIR TEMPERATURE. For a long time, air temperature was used as an index of thermal comfort, but it was realised that air temperature alone was not an adequate index of thermal comfort. (2) AIR TEMPERATURE AND HUMIDITY: Later, air temperature and humidity were considered together to express thermal comfort: even this was found to be unsatisfactory. (3) COOLING POWER: Still later, air temperature, humidity and air movement were considered together and expressed as "cooling power" of the air. An instrument was devised by Hill called the Keta Thermometer to measure the cooling power. A dry Keta reading of 6 and above, and a wet Keta reading of 20 and above, were regarded as indices of thermal comfort. Further researches have shown that the Keta cooling powers are also not reliable indices of comfort conditions. (4) EFFECTIVE TEMPERATURE: Effective temperature is an arbitrary index which combines into a single value the effect of temperature, humidity and movement of the internal air on the sensation of warmth or cold felt by the human body. The numerical value of effective temperature is that of the temperature of still, saturated air which would induce the same sensation of warmth or cold as that experienced in the given conditions. For example, if the environment has an ET value of 30 deg C (86 deg F), it implies that the subjective sensation of it will be same as in a saturated atmosphere of 30 deg C (86 deg F) with no air movement. This scale was evolved in 1953 after a long series of experiments carried out in the Pittsburgh Laboratory of the American Society of Heating and Ventilation Engineers by Houghen and Yaglou. Two scales are available one of which refers to men who are fully clad in indoor clothing. Effective temperature may be obtained from special charts by reference to the three variables (Fig. 1). A criticism of the effective temperature scale is that it ignores the effects of a radiation from the surrounding structures. (5) CORRECTED EFFECTIVE TEMPERATURE: This Index is an improvement over the Effective Temperature Index. Instead of the dry bulb temperature, the reading of the Globe Thermometer is used to allow for radiant heat. That is, the C.E.T. scales deal with all the four factors namely, air temperature, velocity, humidity and mean radiant heat. Whenever a source of radiation is present, it is preferable to take C.E.T. The C.E.T. may be readily obtained from prepared nomograms by reference to the globe thermomter temperature, the wet bulb temperature and air speed. At present, effective temperature and C.E.T. scales are widely used as indices of thermal comfort (1). McARLIEE'S MAXIMUM ALLOWABLE SWEAT RATE: McArleie and associates took 45 litres of sweat excreted in four hours as the maximum allowable sweat rate compatible with physiological normal reaction of acclimatised healthy young men for repeated exposures to heat. They prepared a chart from which the predicted four-hour sweat rate (P4SR) can be obtained from any combination of dry and wet bulb temperature of the air, mean radiant air temperature and air velocity, under different work intensity McArleie has put P4SR value of 0.5 as an upper limit of comfort zone (2).

Comfort zones

Comfort zones may be defined as the range of ET over which the majority of adults feel comfortable. There is no unanimous decision on a single zone of comfort for all people because comfort is quite a complex subjective experience which depends not only on physical, physiological factors, but also on psychological factors which are difficult to determine. Considering only the environmental factors, "comfortable thermal conditions are those under which a person can maintain normal balance between production and loss of heat, at normal body temperature and without sweating". Comfort zones evaluated in India are as below:

- | Corrected effective temperature in deg C |
- | 1. Pleasant and cool | 20 |
- | 2. Comfortable and cool | 20-25 |
- | 3. Comfortable | 26-27 |
- | 4. Hot and uncomfortable | 27-28 |
- | 5. Extremely hot | 28+ |
- | 6. Intolerable hot | 30 |

Predicted four-hour sweat rate (P4SR)

- | 1. Comfort zone | 1-3 litres |
- | 2. Just tolerable | 3-4.5 litres |
- | 3. Intolerable | 4.5 + litres |

AIR POLLUTION

The phenomenon called "pollution" is an inescapable consequence of the presence of man and his activities. The term "air pollution" signifies the presence in the ambient (surrounding) atmosphere of substances (e.g., gases, mixtures of gases and particulated matter) generated by the activities of man in concentrations that interfere with human health, safety or comfort, or injurious to vegetation and animals and other environmental media resulting in chemicals entering the food chain or being present in drinking-water and thereby constituting additional source of
human exposure. The direct effects of air pollutants on plants, animals and soil can influence the structure and function of ecosystems, including self regulation ability, thereby affecting the quality of life (2). In the past, air pollution meant smoke pollution. Today, air pollution has become more subtle and recognizes no geographical or political boundaries. Air pollution is one of the present-day health problems throughout the world.

Basic definitions (4)

Before discussing in detail the sources of air pollutants it is necessary to establish a few basic principles that will place the information on sources in context. Air pollutants may be either emitted into the atmosphere or formed within the atmosphere itself.

Primary air pollutants: Primary air pollutants are those that are emitted into the atmosphere from a source such as a factory chimney or exhaust pipe, or through suspension of contaminated dust by the wind. In principle, therefore, it is possible to measure the amounts emitted at the source itself.

Secondary air pollutants: Secondary air pollutants are those formed within the atmosphere itself. They arise from chemical reactions of primary pollutants, possibly involving the natural components of the atmosphere, especially oxygen and water. The most familiar example is ozone, which arises almost entirely from chemical reactions that differ with altitude within the atmosphere. Because of this mode of formation, secondary pollutants cannot readily be included in emissions inventories, although it is possible to estimate formation rates per unit volume of atmosphere per unit time.

Another important distinction must be made in relation to the physical state of a pollutant.

Gaseous air pollutants: Gaseous air pollutants are those present as gases or vapours, i.e. as individual small molecules capable of passing through filters, provided they do not adsorb to or chemically react with the filter medium. Gaseous air pollutants are readily taken into the human respiratory system, although if water-soluble, they may very quickly be deposited in the upper respiratory tract and not penetrate to the deep lung.

Particulate air pollutants: Particulate air pollutants comprise material in solid or liquid phase suspended in the atmosphere. Such particles can be either primary or secondary and cover a wide range of sizes. Newly formed secondary particles can be as small as 1–2 μm in diameter, while coarse dust and sea salt particles can be as large as 100 μm in diameter. (Please note – 1 μm is one millionth of a metre = 1 micron = 0.001 mm)

Local scale: Some pollutants, by virtue of their source or of having a very short atmospheric lifetime, are only encountered in appreciable concentrations close to where they are emitted. For example in less developed countries, poorly controlled household and neighbourhood sources, often involving the burning of biomass fuels, cause serious local pollution.

Urban scale: Pollutants from urban sources, such as nitrogen oxides and carbon monoxide generated by road traffic, tend to be present at high concentrations throughout the city and at significantly reduced concentrations in adjacent rural areas. Their atmospheric lifetimes are not long (typically hours) and therefore concentrations in the remote background atmosphere tend to be very low (except in the case of carbon monoxide, which is more persistent).

Regional scale: Pollutants in the form of fine particles (<2.5 μm diameter, but not ultrafine particles) and some gas-phase pollutants such as ozone have atmospheric lifetimes of days or even weeks, which permit them to be transported on a regional scale. Pollutants such as sulphate particles and ozone readily travel thousands of kilometres in a process known as long-range transport, crossing national boundaries in doing so.

Hemispheric and global scales: Some pollutants, and especially those associated with greenhouse warming effects (carbon dioxide, nitrous oxide and methane) have atmospheric lifetimes of years and are therefore capable of distribution throughout a hemisphere and ultimately globally.

Sources of air pollution

The main sources of air pollution are:

(a) AUTOMOBILES: Most vehicles are a major source of air pollution throughout the urban areas. They emit hydrocarbons, carbon monoxide, lead, nitrogen oxides and particulate matter. In strong sunlight, certain of these hydrocarbons and oxides of nitrogen may be converted in the atmosphere into “photochemical” pollutants of oxidizing nature. In addition, diesel engines, when exhaust or badly adjusted are capable of emitting black smoke and malodorous fumes.

(b) INDUSTRIES: Industries emit large amounts of pollutants into the atmosphere. Combustion of fuel to generate heat and power produces smoke, sulphur dioxide, nitrogen oxides and fly ash. Petrochemical industries generate hydrogen fluoride, hydrochloric acid and organic halides. Many industries discharge carbon monoxide, carbon dioxide, hydrogen sulphide and sulphur dioxide. Industries discharge their wastes from high chimneys at high temperature and high speed.

(c) DOMESTIC SOURCES: Domestic combustion of coal, wood or oil is a major source of smoke, dust, sulphur dioxide and nitrogen oxides. The London disaster of air pollution in 1952 in which thousands had died was due to domestic coal burning. (d) The most direct and important source of air pollution affecting the health of many people is tobacco smoke. Even those who do not smoke may inhale the smoke produced by others (‘passive smoking’).

(e) MISCELLANEOUS: These comprise burning refuse, incinerators, pesticide spraying, natural sources (e.g., wind borne dust, fungus, molds, bacteria) and nuclear energy programmes. All these contribute to air pollution.

Meteorological factors

Although the Earth’s atmosphere extends to several layers above the surface, it is only the first 30 km that hold the major portion of the atmospheric gases. Man is most directly concerned with only the 8–10 km of the atmosphere (3).

The level of atmospheric pollution at any one time depends upon meteorological factors, e.g., topography, air movement and climate. Winds help in the dispersal and dilution of pollutants. If the topography is dominated by mountains (or tall buildings) the winds become weak and calm, and pollutants tend to concentrate in the treated area.

The vertical diffusion of pollutants depends upon the temperature gradient. When there is a rapid cooling of lower layers of air (temperature inversion), there is little vertical motion and the pollutants and water vapours remain trapped at the lower levels and the result is “smog”. The “temperature inversion” which is more frequent in the winter months than in spring or summer, is a threat to human health.

AIR POLLUTION
Air pollutants
More than 100 substances which pollute air have been identified. The important ones are carbon monoxide, carbon dioxide, hydrocarbons, sulfur dioxide, nitrogen oxides, fluoride compounds, organic compounds (e.g., hydrocarbons, aldehydes, ketones, organic acids), metallic contaminants (e.g., arsenic, zinc, iron resulting from smelting operations, radio-active compounds, photochemical oxidants (e.g., ozone). Others include asbestos, beryllium, mercury, brine, fluorides, vinyl chloride, lead and radiation. Contaminants differ greatly from place to place depending upon specific complex of contaminant source. Pollutants may be in the form of solids, liquids (vapours) or gases. The combination of smoke and fog is called "smog".

(1) Carbon monoxide : Carbon monoxide is one of the most common and widely distributed air pollutants. It is a product of incomplete combustion of carbon containing materials, such as in automobile, industrial processes, heating facilities and incinerators. Estimates of man-made carbon monoxide emission vary from 350 to 600 million tonnes per annum (1). Some widespread natural non-biological and biological sources have also been identified. Concentrations in urban areas depend on weather and traffic density. It varies with the density of petrol-powered vehicles and most cities have carbon monoxide peak levels that coincide with the morning and evening rush-hours. Variations in these levels are also influenced by topography. The fluctuation in ambient concentrations is only slowly reflected in the carbon monoxide levels in humans, as it takes 4-12 hours for approximate equilibrium between air levels and blood levels to occur. Thus environmental concentrations tend to be expressed in terms of 8 hour average concentrations.

(2) Sulphur dioxide : It is one of the several forms in which sulphur exists in air. The others include H$_2$S, H$_2$SO$_4$ and sulphate salts. Sulphur dioxide ($$SO_2$$) is a colourless gas with a sharp odour, results from the combustion of sulphur containing fossil fuel, the smelting of sulphur-containing ores, and other industrial processes. Domestic fires, power generation and motor vehicles can also produce emissions containing sulphur dioxide.

SO$_2$ can affect the respiratory system and the function of lungs, and causes irritation of eyes. Inhalation of the respiratory tract causes coughing, mucus secretion, aggravation of asthma and chronic bronchitis, and makes people more prone to infections of the respiratory tract. Hospital admissions for cardiac disease and mortality increase on days with higher SO$_2$ levels. When SO$_2$ combines with water, it forms sulphurous acid; this is the main component of 'acid rain' which is a cause of deforestation. A SO$_2$ concentration of 500 $\mu$g/m$^3$ should not be exceeded over average periods of 10 minutes duration. Studies indicate that a proportion of people with asthma experience changes in pulmonary function and respiratory symptoms after periods of exposure to SO$_2$ as short as 10 minutes. The revision of 24-hour guideline for SO$_2$ from 125 to 20 $\mu$g/m$^3$ is based on health effects known to be associated with much lower levels of SO$_2$ than previously believed (5).

(3) Lead : The combustion of leaded petrol in motor fuels accounts for the major part of lead emissions into the atmosphere. An estimated 80-90 percent of lead in ambient air derives from the combustion of leaded petrol. The degree of pollution from this source differs from country to country, depending on motor vehicle density and the efficiency of effort to reduce the lead content of petrol. The mining and smelting of lead ores create pollution problems in some areas. Children up to 6 years of age are a population at increased risk for lead exposure, as well as for adverse health effects, as children have behaviour characteristics (outdoor activity) which increase the risk of lead exposure; the blood-brain barrier is not yet fully developed in young children; and haematological and neurological effects of lead occur at lower threshold in children than in adults.

Since the placenta is no effective biological barrier, pregnant women are at increased risk because of exposure of the foetus to lead.

(4) Carbon dioxide : This is not commonly regarded as an air pollutant, although man generates enormous amount of it in combustion process using coal, oil and gas. Carbon dioxide is a natural constituent of the air. It does not take part in any significant chemical reactions with other substances in the air. However, its global concentration is rising above the natural level by an amount that could increase global temperature enough to affect climate markedly (6).

(5) Hydrocarbons : Man-made sources of hydrocarbons include incineration, combustion of coal, wood, processing and use of petroleum. Hydrocarbons exert their pollutant action by taking part in the chemical reactions that cause photochemical smog.

(6) Cadmium : The steel industry, waste incineration, volcanic action and zinc production seem to account for the largest emissions. Incineration is in immediate choice of method of refuse disposal in European countries. This source of atmospheric cadmium pollution is of growing concern. Tobacco contains cadmium, and smoking may contribute significantly to the uptake of cadmium. Cigarettes may contain from 0.5 to 8 $\mu$g cadmium per gram of tobacco, depending on the country of origin.

(7) Hydrogen sulphide : Human activities can release naturally occurring hydrogen sulphide into ambient air. In industry, hydrogen sulphide can be formed whenever elemental sulphur or sulphur containing compounds come in contact with organic material at high temperatures. Hydrogen sulphide is formed during coke production, in VOSO$_4$ rayon production, waste-water treatment plants, wood pulp production using the sulphate method, sulphur extraction process, oil refining and in tanning industry. Hydrogen sulphide is the main toxic substance involved in livestock rearing systems with liquid manure storage (7). The first noticeable effect of hydrogen sulphide at low concentration is in unpleasant odour. Conjunctival irritation is the next subjective symptom. Workers exposed to hydrogen sulphide concentrations of less than 30 $\mu$g/m$^3$ are reported to have rather diffuse neurological and mental symptoms (2).

(8) Ozone : Ozone at ground level - not to be confused with the ozone layer in the upper atmosphere - is one of the major constituents of photochemical smog. It is formed by the photochemical reaction of sunlight with pollutants such as nitrogen oxides from vehicle, industry emissions and volatile organic compounds (VOCs) emitted by vehicles, solvents and industry. The highest levels of ozone pollution occur during periods of sunny weather. Excessive ozone in the air can have a marked effect on human health. It can cause breathing problems, trigger asthma, reduce lung function and cause lung diseases. In Europe it is currently
one of the air pollutants of most concern. Several European studies have reported that the daily mortality rises by 0.3% and that for heart diseases by 0.4%, per 10 μg/m³ increase in ozone exposure. The previously recommended limit, which was fixed at 120 μg/m³ of 8-hour mean, has been reduced to 100 μg/m³ on the basis of recent conclusive associations between daily mortality and ozone levels occurring at ozone concentrations below 120 μg/m³ (5).

(9) Oxides of nitrogen: Emission of oxides of nitrogen occur predominantly in the form of nitric oxide, which comprises around 90 per cent of nitrogen oxides from a combustion source. Coal is the most important fuel in this context, other sources are road traffic and electricity generation. The pollutant of far greater concern in relation to human health is nitrogen dioxide. Epidemiological studies have shown that symptoms of bronchitis in asthmatic children increase in association with long-term exposure to nitrogen dioxide. Reduced lung function growth is also linked to nitrogen dioxide at concentrations currently measured (or observed) in the cities of Europe and North America. The current WHO guideline value of 40 μg/m³ (annual mean) set to protect the public from the health effects of gaseous nitrogen dioxide remains unchanged from the level recommended in the previous AOGs.

(10) Polycyclic aromatic hydrocarbons (PAH): Polycyclic aromatic hydrocarbons (PAHs) (also known as polynuclear aromatic hydrocarbons) are a group of approximately 10,000 compounds. The examples are Benzo[a]pyrene (BaP), Benzo[a]anthracene, Benzo[b]fluoranthene, Benzo[k]fluoranthene, Naphthalene etc. BaP is commonly used as an indicator species for PAH contamination and most available data refer to this compound. Most PAHs in the environment are produced by incomplete burning of carbon containing material like wood, garbage, coal and oil. Automobile exhaust, industrial emission and smoke from burning wood, charcoal and tobacco contain high levels of PAHs. In general, most PAHs form when materials burn at low temperatures, such as in wood fires and cigarettes. The fine PAH particles can bind with ash particles and can move long distances. PAH can also be toxic when ingested or when they come in contact with skin (they are used in some skin creams and anti-dandruff shampoos). When inhaled, some PAHs are carcinogenic, mutagen and reproductive toxin (BaP is one of the most potent carcinogens among the known PAHs). A person who smokes one pack of filtered cigarettes per day is exposed daily to 2 to 5 μg of carcinogenic PAHs. Occupational exposure can occur through inhalation and dermal contact. People with highest exposure are smokers, people who live with or work with smokers, roosters, road builders and people who live near major highways or industrial sources.

Based on epidemiological data from studies on coke-oven workers, a unit risk for lung cancer for PAH mixture is estimated to be 8.7 x 10⁶ mg/m³ BaP. This is the guideline for PAH in indoor air. The corresponding concentration of lifetime exposure to BaP producing excess lifetime cancer risks of 1/1000, 1/100,000 and 1/1,000,000 are estimated to be 1.5, 0.17 and 0.012 μg/m³ respectively (8).

(11) Particulate matter: Airborne particulate matter represents a complex mixture of organic and inorganic substance. Particles are generally classified by their size measured in μm (micro meter, i.e. one millionths of a metre). Initially guidelines were directed at very general measure of PM concentration including total suspended particulate (TSP) matter in US, and black smoke (BS) in Europe. In 1987, USEPA promulgated a standard for PM — less than 10 μm in aerodynamic diameter (PM₁₀). In 1997, a standard for PM less than 2.5 μm in aerodynamic diameter (PM₂.₅) was added. By definition PM₁₀ includes PM₂.₅ and thoracic coarse mass PM (the difference between PM₁₀ and PM₂.₅) is removed from the coarse mass PM. PM₂.₅ includes all inhalable particles that are sufficiently small to penetrate to the thoracic region; the fine fraction of PM₂.₅ cut-off from coarse fraction at 2.5 μm, a size fraction with a high probability of deposition in the smaller conducting airways and alveoli.

The major components of PM are sulfate, nitrates, ammonium, sodium chloride, black carbon, mineral dust and water. It consists of a complex mixture of solid and liquid particles of organic and inorganic substances.

The large particles typically contain earth’s coastal material and fugitive dust from roads and industries. Particular matter of respirable size may be emitted from a number of sources, some of them natural (e.g., dust storms) and many others that are more widespread and more important (e.g., power plants and industrial processes, vehicular traffic, domestic coal burning, industrial incinerators). The particulate matter of diameter smaller than 2.5 μm are more dangerous since, when inhaled, they may reach the peripheral regions of the bronchiol, and interfere with gas exchange inside the lungs. The effects of PM on health occur at levels of exposure currently being experienced by most urban and rural populations in both developing and developed countries. Chronic exposure to particles contributes to the risk of developing cardiovascular and respiratory diseases. In developing countries, exposure to pollutants from indoor combustion of solid fuels on open fires or traditional stoves increases the risk of respiratory and cardiovascular diseases mortality among young children; indoor air pollution from solid fuel use is also a major risk factor for chronic obstructive pulmonary disease mortality for adults. The mortality in cities with high levels of pollution exceeds that observed in relatively cleaner cities by 15-20 per cent. The 2005 AOG set for the first time a guideline value for particular matter (PM) as 10 μg/m³ annual mean and 25 μg/m³ 24-hour mean for PM₁₀, and 20 μg/m³ annual mean and 50 μg/m³ 24-hour mean for PM₂.₅. (9) The aim is to achieve the lowest concentrations possible. As no threshold for PM has been identified below which no damage to health is observed, the recommended value should represent an acceptable and achievable objective to minimize health effects in the context of local constraints, capabilities and public health priorities.

Indoor air pollution (4)

The indoor environment represents an important microenvironment in which people spend a large part of their time each day. As a result, indoor air pollution, originating from both outdoor and indoor sources, is likely to contribute more to population exposure than the outdoor environment. The extent and magnitude of consequent health risks, however, remain poorly understood. The large number of indoor air pollutants, including chemical and biological contaminants, and the influence of a variety of factors such as the nature and location of sources, air exchange between indoor and outdoor environments, and individual behaviour make accurate estimations of health effects very difficult.

The major sources of indoor air pollution worldwide
include combustion of solid fuels indoors, tobacco smoking, outdoor air pollutants, emissions from construction materials and furnishings, and improper maintenance of ventilation and air conditioning systems (Table 1). There are, however, marked variations in the importance of these different sources in different areas of the world, closely related to the level of socioeconomic development.

Although relatively clean sources of household energy predominate in developed countries, improvements in energy efficiency have led to homes being relatively airtight, reducing ventilation and raising indoor pollutant levels. 4.3 million people die every year prematurely from illness attributable to the household air pollution caused by inefficient use of solid fuels. Among these deaths 12 per cent are due to pneumonia, 34 per cent from stroke, 26 per cent from ischaemic heart disease, 22 per cent from COPD and 6 per cent from lung cancer.

Exposure to household air pollution almost doubles the risk for childhood pneumonia. Over half of deaths among children less than 5 years old in acute lower respiratory infections (ALRI) are due to particulate matter inhaled from indoor air pollution from household solid fuels.

Nearly one quarter of all premature deaths due to stroke (i.e. about 1.4 million deaths of which half are in women) can be attributed to the chronic exposure to household air pollution caused by cooking with solid fuels. Approximately 15% of all deaths due to ischaemic heart disease, accounting for over a million premature deaths annually, can be attributed to exposure to household air pollution. Over one-third of premature deaths from chronic obstructive pulmonary disease (COPD) in adults in low and middle-income countries are due to exposure to household air pollution. Women exposed to high levels of indoor smoke are 2.3 times as likely to suffer from COPD than women who use cleaner fuels. Among men who already have a heightened risk of COPD due to their higher rates of outdoor air pollution, smoke nearly doubles that risk. Approximately 17% of annual premature lung cancer deaths in adults are attributable to exposure to the severity for population. For example, the following graph with solid fuels like wood, charcoal or coal. The risk for women is higher, due to their role in food preparation. More people are poisoned by indoor air pollution and the risk for women is higher, due to their involvement in food preparation. As indoor smoke inflame the airways and lungs, impairing immune response and reducing the oxygen-carrying capacity of the blood. There is also evidence of links between household air pollution and low birth weight, tuberculosis, cataract, nasopharyngeal and laryngeal cancers (44).

### Monitoring of air pollution

The best indicators of air pollution are sulphur dioxide, smoke and suspended particles. They are monitored on a daily basis over several sites. The results are then collected by a central agency. (a) Sulphur dioxide: This gas is a major contaminant in many urban and industrial areas. Its concentration is estimated in all air pollution surveys. (b) Smoke or soiling index: A known volume of air is filtered through a white filter paper under specified conditions and the stain is measured by photoelectric meter. Smoke concentration is estimated and expressed as micrograms/ cubic metre of air as an average level over a period of time. (c) Grid and dust measurements: Deposit gauges collect grit, dust and other solids. These are analyzed monthly. (d) **Coefficient of haze**: A factor used, particularly in the USA to measure the amount of smoke or other aerosol in air. (e) **Air pollution index**: It is an arbitrary index which takes into account one or more pollutants as a measure of the severity of pollution. For example, the following graph has been used in USA: 10 times the sulphur dioxide concentration plus twice the carbon monoxide concentration (both in parts by volume) plus twice the coefficient of haze. It was considered to be a cause for alarm when the value of this index rose from its value of about 12-50 or more.

The WHO (1987) in its publication "Air quality guidelines for Europe" and more recently 2005 ed. has described approved methods of determining the concentration of common air pollutants and their health hazards. The emphasis in the guideline is placed on exposure, since this is the element that can be controlled to lessen the dose and hence lessen response. The starting point for the derivation of guideline value was to define the lowest concentration at which adverse effects are observed. On the basis of the body of scientific evidence and judgments of protection (safety) factors, the guideline values were established. The regulatory approach to controlling air pollution differs from country to country as several source of air pollutants having unique national components are best subject to national control procedures. The approach taken in the preparation of the air quality guidelines was to evaluate data on health effects of individual compounds. As part of this approach, each chemical is considered in isolation. Inevitably, there is little empirical evidence for such factors as interaction between pollutants that might lead to synergistic effects and on the environmental fate of the pollutants. For some of the substances, a direct relationship between concentrations in air and possible toxic effects is very difficult to establish. This is especially true of those metals for which a greater body burden results from ingestion than from inhalation. For example, available data show that the food chain is, for most

Air pollution monitoring in India

The National Air Quality Monitoring Programme, sponsored by the Central Pollution Control Board (CPCB) since 1990, has generated data over last 14 years in 10 major Indian cities, viz. Ahmedabad, Mumbai, Kolkata, Delhi, Hyderabad, Jaipur, Kanpur, Kochi, Chennai and Nagpur. The programme facilitates evaluation of long-term air quality trends for health-related criteria pollutants such as inhalable dust, sulphur dioxide, nitrogen dioxide, lead, hydrogen sulphide, ammonia and PAH. The trend analysis showed that Suspended Particulate Matter (SPM) exceeds the CPCB standard in all cities most of the time throughout the year. The concentration ratio of < P10 fraction (human respirable particles) to the total SPM varies between 30 to 60 per cent, with coastal cities showing higher percentages. The concentration of respirable suspended particulate matter is invariably higher at the industrial sites. The PAH in suspended particles at various sites did not show specific trend. The BaP concentration was higher than the CPCB standard at Ahmedabad, Mumbai, Kolkata, Delhi and Nagpur in winter months. Chromium, copper, nickel, arsenic, lead, iron, zinc, sulphate, nitrate, chloride, fluoride, ammonia, sodium and potassium are secondary pollutants and are identified in the air pollutants. Wet deposition of air pollution has also been evaluated by analyzing rain water samples at all monitoring stations. The analysis shows the highest deposition for the first rain event has the maximum concentration of pollutants with low pH values and higher sulphate and nitrate contents. The acid rain phenomenon thus prevails, albeit for a limited period, in the urban atmosphere of Indian cities (9).

Effects of air pollution

About 1.3 billion urban residents worldwide are exposed to air pollution level above recommended limits. Air quality in the developed countries has generally improved in the past two decades, but in many developing countries air quality has deteriorated because of rising industrial activity, increasing power generation and the congestion of streets with poorly maintained motor vehicles that use leaded fuel. Air pollution can affect by two ways:

(a) Health aspects: The health effects of air pollution are both immediate and delayed. The immediate effects are borne by the respiratory system, the resulting state is acute bronchitis. If the air pollution is intense, it may result even in immediate death by suffocation. This has taken place in the air pollution epidemic which occurred in London in 1952. The delayed effects most commonly linked with air pollution are chronic bronchitis, lung cancer, bronchial asthma, emphysema, and respiratory allergies.

Lead poisons many systems in the body and is particularly dangerous to children developing brain and nervous systems. Elevated lead levels in children have been associated with impaired neuropsychologic development as measured by loss of IQ, poor school performance and behavioural difficulties (10). Table 3 shows the major air pollutants, their sources and adverse effects on health.

COVID – Chronic obstructive pulmonary disease

Source: (11, 12)
VENTILATION: This reduces vitiated air and bacterial density. (2) ULTRAVIOLET RADIATION: This has been found to be effective in special situations such as operation theatres and infectious disease wards. Since direct exposure to ultraviolet rays is a danger to the eyes and skin, the ultraviolet lamps are shaded and located in the upper portion of the rooms near the inlet of air. Ultraviolet rays have proved effective for general use in public assembly and school rooms. (3) CHEMICAL MISTS: Triethylene glycol vapours have been found to be effective air bactericides, particularly against droplet nuclei and dust. (4) DUST CONTROL: Application of oil to floors of hospital wards reduces the bacterial content of the air. Air disinfection is still in the experimental stage.

3,000 c.f.t. of air would be required by a man at rest per hour. This standard of ventilation is no longer followed. (2) Air change: It is now established that the carbon dioxide theory is not quite correct because even if the CO₂ content of air is raised to over 5 per cent and the O₂ content reduced to 18 per cent, there were no deleterious effects so long as the “cooling power” of the air was satisfactory. Air change is more important than the cubic space requirement. It is recommended that in the living rooms, there should be 2 or 3 air changes in one hour; in work rooms and assemblies 4 to 6 air changes. If the air is changed more frequently, i.e., more than 6 times in one hour, it is likely to produce a draught which should be avoided. Based on this concept, it is now considered that a space of 1,000 to 1,200 c.f.t. per person is quite sufficient. The number of air changes per hour is calculated by dividing the total hourly air supply to the room by the cubic capacity of the room. (1) (3) Floor space: Floor space per person is even more important than cubic space. Heights in excess of 10 to 12 feet are ineffective from the point of view of ventilation, as the products of respiration tend to accumulate in the lower levels. Therefore, in calculating cubic space requirements, heights over 10 to 12 feet are not taken into account. The optimum floor space requirements per person vary from 50 to 100 sq.ft.

Types of ventilation

1. NATURAL VENTILATION

Natural ventilation is the simplest system of ventilating small dwellings, schools and offices. In this method, reliance is placed on certain forces which operate in nature. These are: (1) THE WIND: The wind is an active force in ventilation. When it blows through a room, it is called perforation. When there is an obstruction, it bypasses and exerts a suction action at its tail end — this is called aspiration. Doors and windows facing each other provide “cross-ventilation”. Back to back houses do not permit cross-ventilation and therefore, their construction is not allowed. (2) DIFFUSION: Air passes through the smallest openings or spaces by diffusion. This is a slow process and therefore, is not relied upon as the sole means of ventilation. (3) INEQUALITY OF TEMPERATURE: Air flows from high density to low density; it rises when slightly heated and escapes from openings provided high up in the room. The outside air which is cooler and more dense will enter the room through inlets placed low. The greater the temperature difference between outside and inside air, the greater the velocity of the incoming air. In the tropics the outside air may be hotter than the inside and the reverse may take place (2). These properties of air are utilized to best advantage by the proper location of windows, doors, ventilators and skylights. The chief drawback of natural ventilation is that it is not possible to regulate the velocity of the incoming air or to adjust its temperature or humidity.

2. MECHANICAL VENTILATION

Mechanical or artificial ventilation may be of the following types:

(1) Exhaust ventilation. (2) Plenum ventilation. (3) Balanced ventilation. (4) Air conditioning.

(1) EXHAUST VENTILATION: In this system, air is extracted or exhausted to the outside by exhaust fans usually driven by electricity. As air is exhausted, a vacuum is created which induces fresh air to enter the room through windows, doors and other inlets. Exhaust ventilation is generally provided in large halls and auditoria for removal of vitiated air. The exhaust fans are housed in apertures in the required walls, high up near the roof which facilitates removal of the upper layers of the heated light air. The ventilation may be regulated by adjusting the speed of the fan. L. exhaust vents are widely used in factories to remove dusts, fumes and other concentrated contaminants at their source. (2) PLENUM VENTILATION: In this system, fresh air is drawn into the room by centrifugal fans so as to create a positive pressure, and displace the vitiated air. Plenum or propulsion system is used for supplying air to air-conditioned buildings and factories. Air is delivered through ducts at desired points. This system is of limited utility. (3) BALANCED VENTILATION: This is a combination of the exhaust and plenum systems of ventilation. The blowing fan must balance the exhaust fan. When this system is employed, the natural system of ventilation is entirely dispensed with. (4) AIR CONDITIONING: Air conditioning is defined as “the simultaneous control of all, or at least the first three of those factors affecting both the physical and chemical conditions of the atmosphere within any confined space or room. These factors include temperature, humidity, air movement, distribution, dust, bacteria, odours and toxic gases, most of which affect in greater or lesser degree the human health and comfort”. Air conditioning is popular in large institutions, hospitals, industries and dwellings. Its use in operation theatres is of particular value in control of pathogenic organisms in the air. The air is filtered when drawn into an airconditioner system from the room. Excess humidity is removed and the air is circulated back into the room after heating or cooling it, to bring room temperature to required comfort zone. Mixing some percentage of fresh air with recirculated air is regulated. Large institutions or hospitals often install central airconditioning system for entire building, wherein of installing equipments for individual rooms. Better controls and economy is achieved in central airconditioning.

Where the temperature difference is large between outside atmosphere and airconditioned room, “transition room” is sometimes provided, which maintains temperature in between the two, so as to prevent sudden exposure to high or low temperature.

The requirements of good lighting

Good lighting is essential for efficient vision. If the lighting conditions are not ideal, the visual apparatus is put to strain which may lead to general fatigue and loss of efficiency. For efficient vision, the following light factors are essential:

(1) SUFFICIENCY: The lighting should be sufficient to enable the eye to discern the details of the object as well as the surroundings without eye strain. An illumination of 15 to 20 foot candles (1 foot candle = 10.76 Lux) is accepted as a basic minimum for satisfactory vision. The illumination requirements vary from as little as 5 foot candles in stairways and corridors to 100 foot candles in some industries. (2) DISTRIBUTION: The distribution of light should be uniform, having the same intensity, over the whole field of
work. If there are contrast differences in light, it will strain the eyes and affect adversely the visual acuity. Proper dispersion of light, without the production of shadows is therefore necessary for efficient vision. (3) ABSENCE OF GLARE: Glare is excessive contrast. The best example of glare is the automobile headlights at night, the same light during daylight would not cause glare owing to the absence of excessive contrast. Glare may be a direct glare from a light source or reflected glare from sootines such as table tops and polished furniture. Glare causes annoyance. The eye cannot tolerate glare because it causes acute discomfort and reduces critical vision. (4) ABSENCE OF SHARP SHADOWS: Slight shadows are inevitable, but sharp and contrasting shadows are disturbing. Like glare, shadows cause confusion to the eye and therefore should not be present in the field of vision. (5) STEADINESS: The source of light should be constant. It should not flicker because flickering causes eye strain and may lead to accidents. (6) COLOUR OF LIGHT: The colour of light is not very important so long as the intensity is adequate. Since natural light has a soothing effect on the eye, the artificial light should as far as possible approximate the daylight colour. (7) SURROUNDINGS: When a black object is viewed against a dark background, recognition is difficult. High levels of illumination will be required where there is little colour contrast. For efficient vision, colour schemes in rooms are important. Ceilings and roofs should have a reflection factor of 80 per cent; walls 50 to 60 per cent; furniture 30 to 40 per cent. There should not be much reflection from the floor, not more than 15 to 20 per cent. Contrasting colours are often used to prevent accidents, e.g., culverts, bridges, etc.

Measurement of light
What we perceive as light is a narrow wavelength band of electromagnetic radiation from about 380 to 780 nm (nano metre). Light containing all visible waves is perceived as white. There is considerable confusion about units of light measurement. There are four measures of importance. For each of these four measures again, there are a number of terms and also a great variety of names. These are given in Table 1. The four measures are: (1) Luminous intensity, which is the "power" of a light source considered as a point radiating in all directions; this is measured as candela or candle power: (2) Luminous flux, which is the flow of light related to a unit of solid angle measured in lumen. (3) Illumination or illuminance, which is the amount of light reaching a surface measured in lux per unit area; and (4) Brightness or luminance which is the amount of light reflected from a surface measured in lambert.

Natural lighting
Natural lighting is derived partly from the visible sky and partly from reflection. In fact, much light comes to the room by reflection from light coloured objects. Efficient utilization of natural light calls for careful design, location and orientation of buildings and relationship between buildings (town planning). Natural lighting also depends upon the time of the day, season, weather and atmospheric pollution. Since natural light is accompanied by radiant heat, all attempts should be made to exclude radiant heat while admitting daylight.

Suggestions for improving daylight illumination: The following general principles are taken into consideration in planning for the best utilization of daylight.
(1) ORIENTATION: The brightness of the sky is not constant on the east and west and therefore the illumination is subject to variation with the time of the day facing east or west. Further, the direct penetration of sunlight from the east or west may heat up the rooms unduly in the tropics, especially during the summer. Buildings should therefore be oriented, wherever possible, towards north or south for uniform illumination. This is particularly important in respect of schools, factories and laboratories where uniform lighting is required in all the rooms. This rule may not be strictly observed with regard to dwelling houses, as uniform lighting is not required in all the rooms. When a building faces east and west, window shades are provided to protect against the direct penetration of sunlight. (2) REMOVAL OF OBSTRUCTIONS: Removal of obstructive items either wholly or partially is likely to give the most effective single improvement in lighting. (3) WINDOWS: Windows should be properly planned, as the natural lighting within any room is influenced by the amount of visible sky, the size, shape and arrangement of the window openings. A tall window gives greater penetration of light; a broad window gives greater diffusion of light. The rule that window area should not be less than 10 per cent of the floor area is now outdated. In modern practice, window area is correlated to the purpose the room is intended to serve. The usefulness of the windows is reduced by covering them unnecessarily with curtains and screens. (4) INTERIOR OF THE ROOMS: In order to obtain the full benefit of the natural illumination, the ceiling should be white; the upper portions of the walls light-tinted; and lower portions somewhat darker so as to give comfortable contrast to the eyes. The desirable reflection factors of the walls, roof and furniture have already been discussed.

Measurement of daylight
Since the intensity of daylight illumination is liable to change from moment to moment, it is not measured in terms of foot candles. Reliance is placed on a factor called the DAYLIGHT FACTOR (D.F.). It is the ratio of illumination at a given point to illumination at a point exposed simultaneously to the whole hemisphere of the sky (taken as 500 foot candles) excluding direct sunlight. The daylight factor may be summarized as follows:

\[
D.F. = \frac{\text{Instantaneous illumination INDOORS}}{500} \times 100
\]

Simultaneously occurring illumination OUTDOORS

The daylight factor in a building may be rapidly determined by a modified photo-electric meter known as a Daylight Factor Meter. It is recommended that in living
**Artificial lighting**

Daylight may not meet the requirements of illumination during all hours, and especially during cloudy days. It should therefore be supplemented by artificial illumination for adequate illumination. Artificial lighting should be as close as possible to daylight in composition. There are five systems of artificial lighting: direct, semi-direct, indirect, semi-indirect and direct-indirect. (1) DIRECT LIGHTING: In direct lighting, 99 to 100 per cent of the light is projected directly towards the working area. Direct lighting is efficient, economical, but tends to cast sharp shadows. It should not fall into the eyes. (2) SEMI-DIRECT: Here 10 to 40 per cent of the light is directed upwards so that it is reflected back on the object by the ceiling. (3) INDIRECT: light does not strike a surface directly, because 90 to 100 per cent of the light is projected towards the ceiling and walls. This gives a general illumination of the whole room but not of any object. (4) SEMI-INDIRECT: Here, 60 to 90 per cent of the light is directed upwards, and the rest downwards. (5) DIRECT-INDIRECT: Here, light is distributed equally. No one system can be recommended to the exclusion of others.

**Methods of artificial illumination**

(1) FILAMENT LAMPS: These are widely used. The electric current heats up the tungsten filament and the light emitted depends upon the temperature. The hotter filaments produce the bluer light. Accumulation of dust on the bulbs reduces illumination by 30 to 40 per cent. The bulbs and shades therefore should be cleaned frequently.

(2) FLUORESCENT LAMPS: Fluorescent lamps are economical in the use of electric current; they are cool and efficient; the light emitted simulates natural light. The lamps consist of a glass tube filled with mercury vapour and an electrode fitted at each end. The inside of the tube is coated with fluorescent chemicals, which absorb practically all the ultraviolet radiation and remit the radiation in the visible range. The total emission of energy from the 2 lamps is as follows (1).

**Lighting standards**

The eye responds to a range of illumination ranging from 0.1 lux (full moonlight night) to 100,000 lux (bright sunshine). There is considerable confusion about standards because of the adaptability of the eye. Many standards have been published but these standards are arbitrary. The visual efficiency increases with the increase of illumination, but the curve flattens out at higher levels. The law of diminishing return applies. A useful rule of thumb is that the illumination level should be 30 times higher than the level at which the task can just be done. It is worth repeating there are no exact lighting standards and it is usually better to err on the side of too much light, provided glare can be avoided. For practical situations and various activities, the following values in lux have been suggested by the Illuminating Engineer Society (1).

**Biologic effects of light (2, 3)**

Considerable attention has been focused on the biologic effects of light. The observation that daylight could cause the in vitro degradation of billrubin is now being used as a therapeutic measure in premature infants with hyperbilirubinemia. Other biologic effects of light include effect on biologic rhythms of body temperature, physical activity, the stimulation of melanin synthesis, the activation of precursors of vitamin D, adenocortical secretion and food consumption.

**References**

**Noise**

Noise is often defined as "unwanted sound", but this definition is subjective because of the fact that one man's sound may be another man's noise. Perhaps a better definition of noise is: "wrong sound, in the wrong place, at the wrong time". Man is living in an increasingly noisy environment. The 20th Century has been described as the "Century of Noise". Noise has become a very important "stress factor" in the environment of man. The term "Noise Pollution" has been recently coined to signify the vast cacophony of sounds that are being produced in the modern life, leading to health hazards.

**Sources**

The sources of noise are many and varied. These are automobiles, factories, industries, air-crafts etc. Noise levels are particularly acute near railway junctions, traffic round-abouts, bus terminuses and airports. Use of pressure horns, recreational noise of loudspeakers with full volume during festivities particularly at night are other sources of noise production. The domestic noises from the radios, transistors, TV sets — all add to the quantum of noise in daily life.

**Properties**

Noise has two important properties: loudness or intensity, and frequency (1).

(1) **LOUDNESS:** Loudness or intensity depends upon the amplitude of the vibrations which initiated the noise. The loudness of noise is measured in decibels (dB). When we say that sound is 60 dB, it means that it is 60 dB more intense than the smallest distinguishable noise or the "reference" sound pressure, which is understood to be 0.0002 microbar or dynes/cm². A dyne is 1/1000,000th of atmospheric pressure. Normal conversation produces a noise of 60–65 dB, whispering, 20–30 dB, heavy street traffic, 60–80 dB; and boiler factories, about 150 dB. A daily exposure up to 85 dB is about the limit people can tolerate without substantial damage to their hearing. The community noise levels are given in Pg.1.
The sound level of some of the noises are as given in Table 2.

The basic instruments used in studies on noise are:
(1) the "Sound Level Meter" which measures the intensity of sound in dB or dBA; (2) the "Octave Band Frequency Analyzer," which measures the noise in octave bands. The resulting plot shows the "sound spectrum" and indicates the characteristics of the noise, whether it is mainly high-pitched, low-pitched or of variable pitch, and; (3) the "Audiometer" which measures the hearing ability. The zero line at the top in the audiogram represents normal hearing.

Noise-induced hearing loss shows a characteristic dip in the curve at the 4000 Hz frequency.

Effects of noise exposure (2,3):

The effects of noise exposure are of two types: auditory and non-auditory. (1) AUDITORY EFFECTS. (a) Auditory fatigue: It appears in the 90 dB region and greatest at 4000 Hz. It may be associated with side effects such as whistling and buzzing in the ears. (b) Deafness: The most serious pathological effect is deafness or hearing loss. The victim is generally unaware of it in early stages. The hearing loss may be temporary or permanent. Temporary hearing loss results from a specific exposure to noise; the disability disappears after a period of time up to 24 hours following the noise exposure. Most temporary hearing loss occurs in frequency range between 4,000 to 6,000 Hz. Repeated or continuous exposure to noise around 100 dBA may result in a permanent hearing loss; in this, the inner ear damage may vary from minor changes in the hair cell endings to complete destruction of the organs of Corti. When this occurs as a result of occupation in industries, it is called 'occupational hearing loss'. Exposure to noise above 160 dBA may rupture the tympanic membrane and cause permanent loss of hearing. (2) NON-AUDITORY EFFECTS: These are: (a) Interference with speech: Noise interferes with speech communication. In everyday life, the frequencies causing most disturbance to speech communication lie in the 300-500 Hz range. Such frequencies are commonly present in noise produced by road and air traffic. For good speech intelligibility, it is considered that the speech sound level must exceed the SIL (Speech Interference Level) by approximately 12 dB. (b) Annunciation: This is primarily a psychological response. Neurotic people are more sensitive to noise than balanced people. Workman exposed to higher intensity of noise in occupational capacities, were often irritated, short tempered and impatient and more likely to resort to agitation and disrupt production. (c) Efficiency: Where mental

FIG. 1
Community noise levels

It has been observed that the human ear responds in a non-uniform way to different sound pressure levels, that is, it responds not to the real loudness of a sound, but to the perceived intensity. A weighting curve, called curve A has been constructed which takes into account the subjective effects of that sound. Sound-pressure levels are therefore expressed in dB (A), that is in decibels conforming to the weighting curve A, because this reflects the perception of that sound emission by the normal human ear. Acceptable noise levels are as given in Table 1.

Source: (1)

(2) FREQUENCY: The frequency is denoted as Hertz (Hz). One Hz is equal to one wave per second. The human ear can hear frequencies from about 20 to 20,000 Hz, but this range is reduced with age and other subjective factors. The range of vibrations below 20 Hz are infra-audible; and those above 20,000 Hz ultra-sonic. Many animals (e.g., dogs) can hear sounds inaudible to the human ear. Sometimes noise is expressed in psycho-acoustic terms – the phon. The phon is a psycho-acoustic index of loudness. It takes into consideration intensity and frequency.
concentration is to be undertaken, a low level of noise is always desired. Reduction in noise has been found to increase work output. (d) Physiological changes: A number of temporary physiological changes occur in the human body as a direct result of noise exposure. These are: a rise in blood pressure, a rise in intraocular pressure, an increase in heart rate and breathing and an increase in sweating. General symptoms such as dizziness, nausea and fatigue may also occur. Noise interferes with sleep. Noise is also said to cause visual disturbance. It is said to cause a narrowing of pupil, affect colour perception and reduce night vision. (e) Besides affecting health, noise is also significant factor in economic losses. The potential cost of noise induced hearing loss to industry is quite great.

Control of noise

A variety of approaches may be needed to control noise. These include: (1) CAREFUL PLANNING OF CITIES: In planning cities, the following measures should be taken to reduce noise: (a) division of the city into zones with separation of areas concerned with industry and transport; (b) the separation of residential areas from the main streets by means of wide green belts. House fronts should lie not less than 15 metres from the road and the intervening space should be thickly planted with trees and bushes; (c) widening of main streets to reduce the level of noise penetration into dwellings. (2) CONTROL OF VEHICLES: Heavy vehicles should not be routed into narrow streets. Vehicular traffic on residential streets should be reduced. Indiscriminate blowing of the horn and use of pressure horn should be prohibited. (3) TO IMPROVE ACUSTIC INSULATION OF BUILDING: From the acoustic stand-point, the best arrangement is construction of detached buildings rather than a single large building or one that is continuous. Installations that produce noise or disturb the occupants within dwellings should be prohibited. Buildings should be sound-proof where necessary. (4) INDUSTRIES AND RAILWAYS: Control of noise at source is possible in industries. Special areas must be earmarked, outside residential areas, for industries, for railways, marshalling yards and similar installations. When these demands cannot be met, protective green belts must be laid down between the installations and residential areas. (5) PROTECTION OF EXPOSED PERSONS: Hearing protection is recommended for all workers who are consistently exposed to noise louder than 85 decibels in the frequency bands above 150 Hz. Workers must be regularly rotated from noisy areas to comparatively quiet parts in factories. Periodical audiogram check-up and use of ear plugs, ear muffs or other essential protective devices are demanded. (6) LEGISLATION: Many states have adopted legislation providing for controls which are applicable to a wide variety of sources (4). Workers have the right to claim compensation if they have suffered a loss of ability to understand speech. (7) EDUCATION: No noise abatement programme can succeed without people’s participation. Therefore, their education through all available media is needed to highlight the importance of noise as a community hazard.

References

Sources of radiation exposure

Radiation is part of man’s environment. The sources of radiation to which man is exposed are divided into two groups (Table 1).

<table>
<thead>
<tr>
<th>Source</th>
<th>Examples</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>(3) Internal:</td>
<td>(4) Miscellaneous: Television sets, Radio-source dial watches, Isotope tagged products, Luminous marks.</td>
</tr>
</tbody>
</table>

(1) Natural sources: Man is exposed to natural radiation from time immemorial. Natural background radiation arises from three sources: (a) Cosmic rays: The cosmic rays which originate in outer space are weakened as they pass through the atmosphere. At ordinary living altitudes, their impact is about 35 mrad a year. At altitudes above 20 km cosmic radiation becomes important. It has been calculated that a commercial jet pilot receives about 300 mrad per year from cosmic radiation (1). (b) Environmental: (i) Terrestrial radiation: Radioactive elements such as thorium, uranium, radium and an isotope of potassium (40K) are present in man’s environment, e.g., soil, rocks, buildings. It is estimated that man derives about 50 mrad per year from terrestrial radiation. Areas exist (e.g., Kerala in India) where there are rock formations containing uranium, it can be as high as 2,000 mrad a year. (ii) Atmospheric radiation: The external radiation dose from the radioactive gases radon and thoron in the atmosphere is rather small: about 2 mrad per year. (c) Internal radiation: Man is also subjected to internal radiation, i.e., from radioactive matter stored in the body tissues. These radioactive materials include minute quantities of uranium, thorium, and related substances, and isotopes of potassium (40K), strontium (90Sr), and carbon (14C). Internal radiation is thought to inflict about 25 mrad a year on the body as a whole, but may be as high as 70 or 80. All in all, it is estimated that the total natural radiation to which the average person is subjected comes to approximately 0.1 rad a year.

(2) Man-made sources: In addition to natural radiation, man is exposed to artificial or man-made sources. These are: (a) X-rays: The greatest man-made source of radiation exposure to the general population at the present time is medical and dental X-rays. Two distinct groups are involved: (i) patients and (ii) radiologists and medical technicians. When optimum radiographic techniques are employed, the skin dose to the patient from a single X-ray film varies roughly from 0.02 to 3.9 rad. (b) Radioactive fallout: Nuclear explosions release a tremendous amount of energy in the form of heat, light, ionizing radiation and many radioactive substances, the important being the isotopes of carbon (14C), iodine (131I), cesium (137Cs) and...
Some common environmental radiations are as given in Table 2.

Source : (1)

Alpha particles are 10 times as harmful as X-rays, beta particles or gamma rays. Alpha particles, luckily, have little penetrating force. On the other hand, they are quite dangerous if radioactive substance has entered the body (by inhalation or through a wound). Gamma rays and X-rays have short wave lengths; they are deep penetrating radiations. X-rays are manmade, while gamma rays are emitted spontaneously by radioactive elements during their disintegration. Otherwise there is no material difference between gamma rays and X-rays. Cosmic rays also contain ionizing radiations.

The term "non-ionizing radiation" refers to several forms of electromagnetic radiation of wavelengths longer than those of ionizing radiation. As wavelength elongates, the energy value of electromagnetic radiation decreases. So all non-ionizing forms of radiation have less energy than cosmic, gamma, and X-radiation have. In order of increasing wavelength, non-ionizing radiation includes ultraviolet (UV) radiation, visible light, infrared radiation, microwave radiation and radio frequency radiation.

Radiation units

The activity of a radioactive material is the number of nuclear disintegrations per unit of time. The unit of activity is a becquerel (Bq); 1 Bq is equal to 1 disintegration per second. Formerly, the unit of activity was curie (Ci) and 1 Bq corresponds approximately to 27 picocuries.

The potency of radiation is measured in three ways:

1.Roentgen: Roentgen is the unit of exposure. It is the amount of radiation absorbed in air at a given point, i.e., number of ions produced in 1 ml of air. (2)Rad: Rad is the unit of absorbed dose. It is the amount of radioactive energy absorbed per gram of tissue or any material. 1 rad = 0.001 rem (3)Rem: Rem is the product of the absorbed dose and the modifying factors. The rem indicates the degree of potential danger to health. The radiation to which the average citizen is exposed is made up almost of the fast moving, highly penetrating X-rays and gamma rays, where rem and rad are equal (2).

The radiation units (v.i. roentgen, rad, rem) are being replaced by the new SI Units (International System of Units) which are: (a) Coulomb per kilogram (C/kg); replacing the roentgen. 1 roentgen is equal to 2.58 x 10^-4 C kg^-1. It is the unit for exposure. There is no special name for this. (b) Gray (Gy) replacing the rad. It is the unit of absorbed dose, defined as the dose of ionizing radiation that impart 1 joule of energy to 1 kg of absorbing material. 1 rad is equal to 0.1 Gy. (1), and (c) Sievert (Sv) replacing the rem. It is the SI unit of dose equivalent. The dose equivalent of 1 sievert is equal to 100 rems.

Dose equivalent (H): As all types of radiation do not produce the same biological effect per unit of energy absorbed, the concept of dose equivalent has been introduced. The dose equivalent, M (Sieverts) is equal to the absorbed dose, D (grays), multiplied by a quality factor Q which depends upon the density of ionization produced in the tissue by the radiation.

\[ H = QD \]

The factor Q for X-rays and Y-rays and electrons is equal to 1, whereas for a particle it is 20 (3).

Biological effects of radiation

Biological effects of radiation are divided into two categories. The first category consists of exposure to high doses of radiation over a short period of time producing acute or short term effects. The second category represents exposure to low doses of radiation over an extended period of time producing chronic or long-term effect. High doses tend to kill cells, causing organ damage. This in turn may cause what is generally referred to as "Acute Radiation Syndrome". The effects of ionizing radiation can be somatic or genetic as shown below:

**SOMATIC**

- **Immediate**
  - (1) Radiation sickness
  - (2) Acute radiation syndrome

- **Delayed**
  - (1) Leukaemia
  - (2) Carcinogenesis
  - (3) Fetal developmental abnormalities
  - (4) Shortening of life

**GENETIC**

- (1) Chromosome mutations
- (2) Point mutations

The biological response of high dose of radiation is as follows (4):

- < 5 rad: No immediate observable effects
- ~ 5 rad to 50 rad: Slight blood changes may be detected by medical evaluations
- ~ 50 rad to 150 rad: Slight blood changes will be noted and symptoms of nausea, fatigue, vomiting etc. likely.
— 150 rad to 1,100 rad: Severe blood changes will be noted and symptoms appear immediately. Approximately 2 weeks later, some of these exposed may die. At about 300–500 rad, one half of the people exposed will die within 60 days without intensive medical care. The damage is due to the destruction of the blood forming organs. Without white blood cells, infection is likely. At the lower end of the dose range, infection, isolation, and transfusions may provide the bone marrow time to generate new blood cells and full recovery is possible. At the upper end of the dose range, a bone marrow transplant may be required to produce new blood cells.

— 1,100 rad to 2,000 rad: The probability of death increases to 100% within one to two weeks. The initial symptoms appear immediately, a few days later, things get very bad, very quickly since the gastrointestinal system is destroyed. Once the GI system ceases to function, nothing can be done, and medical care is far comfort only.

>2,000 rad: Death is a certainty. At doses above 5,000 rad, the central nervous system (brain and muscles) can no longer control the body functions, including breathing and blood circulation. Everything happens very quickly. Nothing can be done, and medical care is far comfort only.

As noted, there is nothing that can be done if the dose is high enough to destroy the gastrointestinal or central nervous system. That is why bone marrow transplants don’t work.

GENETIC EFFECTS: While somatic effects are recognizable within the life span of the irradiated person, genetic effects would be manifested in the destruction of the offspring. Genetic effects result from injury to chromosomes — chromosome mutations and point mutations. Chromosome mutation is associated with sterility. Point mutation affects the genes.

Radiation protection

The amount of radiation received from outer space and background radiation has been estimated to be 0.1 rad a year. Apparently, this does not at present constitute a hazard. The additional permissible dose from man-made sources should not exceed 5 rad a year. Of the man-made sources, the X-rays constitute the greatest hazard. In routine fluoroscopy, a dose of 4 rad is delivered to a part of the body in about one minute. This implies that unnecessary X-ray examinations should be avoided, especially in the case of children and pregnant women (5). It also implies adequate control and surveillance of X-ray installations, protection of workers, improvement in techniques and improvements leading to dose reduction (6). Effective protective measures include proper use of lead shields and lead rubber aprons. Lead aprons (0.5 mm of lead) will reduce the intensity of scattered X-rays over 90% per cent and should be worn by all workers regularly associated with X-ray procedures (1). Workers must wear a film badge or dosemeter which shows accumulated exposure to radiation since last time the instrument was charged. Besides, periodic medical examinations, regular working hours, recreation, and holidays must be ensured to workers to maintain their state of health.

Radiation protection is the youngest branch of hygiene, and is called radiation-hygience. The International Commission on Radiological Protection (ICRP), the International Atomic Energy Agency (IAEA) and the World Health Organization (WHO) have been active in this field. The ICRP’s recommendations on radiation dose levels (7) for occupational workers and for the general population have been accepted by many countries. It has been recommended that the generic dose to the whole population from all sources additional to the natural background radiation, should not exceed 5 rads over a period of 30 years. The WHO has published permissible radiation levels in drinking water. The IAEA has sponsored many symposia on radioactive waste disposal and associated subjects (8). Its main concern has been to promote peaceful uses of atomic energy and to assure that these uses do not imperil peace or health. In short, there has been a worldwide interest in preparing safety standards, codes of practice and nuclear power plants and enunciating the basic principles of radiation protection.

MeteoroLOGICAL ENVIRONMENT

The elements which comprise the meteorological environment are: (1) atmospheric pressure (2) air temperature (3) humidity (4) rainfall (5) direction and speed of wind and (6) movement of clouds and character of weather (1). The term “climate” is a geographical concept representing a summation of the whole range of meteorological phenomena.

Atmospheric pressure

The atmospheric pressure at earth’s surface close to the sea level averages 760 mm of Hg. This is called “one atmosphere of pressure”. Man is physiologically adapted to live at 760 mm of Hg pressure or close to it. The atmospheric pressure falls as altitude increases, and rises as altitude decreases. Thus, at an altitude of 100,000 feet above mean sea level, the atmospheric pressure is less than 10 mm of Hg. The pressure increases at the rate of “one atmosphere” for each 33 feet depth below sea level.

Measurement

The instruments used for measuring atmospheric pressure are known as barometers of which there are three well-known kinds: Fortin’s Barometer; the New Pattern Station Barometer and the Barograph. The ‘New Pattern’ Station Barometer is widely used by the Indian Meteorological Department for measuring the atmospheric pressure. Barograph is an instrument for obtaining a continuous record of atmospheric pressure. It is a circular box, the walls of which collapse or expand according to the atmospheric pressure rises or falls.
Effects of atmospheric pressure on health

HIGH ALTITUDES

The air is less dense at higher altitudes, and consequently the partial pressure of oxygen is also less. Man cannot survive at an altitude of 25,000 feet without breathing equipment. When man is exposed to low pressures, the physiological effects are: (1) increase in respiration (2) increase in the concentration of haemoglobin (3) increase in cardiac output.

Two conditions have been described as a result of sudden exposure to high altitude: (1) Acute Mountain Sickness: This is a relatively common condition that develops, and transient condition characterised by headache, insomnia, breathlessness, nausea, vomiting and impaired vision. It has not been conclusively proved whether all these symptoms are due to the effect of hypoxia or due to the various intricate biochemical and hormonal disturbances in the body. (2) High Altitude Pulmonary Oedema: The symptoms generally appear on about the third day at high altitude and are indistinguishable from those of ordinary mountain sickness. But as pulmonary oedema develops, the patient develops a cough, and may experience irregular or Cheyne-Stokes breathing, oliguria, mental confusion and hallucinations, stupor, seizures and coma. The condition is rare below 12,000 ft. (3,600 m.). The condition does not respond to antibiotics. The patient should be carried to lower altitudes as soon as possible. At present, the causes and mechanisms of high altitude pulmonary oedema are not well understood. The main knowledge of this condition has been gained by medical officers in the Indian Army, who have seen many cases among troops transported from the lowlands to Himalayan stations (2,3).

LOW ALTITUDES

The atmospheric pressure increases by one atmosphere for every 33 feet depth below sea level. The greatest depth so far reached is the equivalent of 10 atmospheres. When man is exposed to high pressure, the gases in the air namely oxygen, carbon dioxide and nitrogen are dissolved in the blood and tissues proportionately to the pressure of the gases in the air. Excessive concentration of nitrogen and carbon dioxide narcotic action leading to loss of mental functions and consciousness; excess of carbon dioxide increases the rate of respiration, it can lead to convulsions and death. When the person comes up to the surface, the gases which are dissolved in the blood under pressure are released and cause air embolism, the effects of which are fatal. The effects of increased pressure are best observed in persons working in diving bells and in compressed air chambers (Caisson disease).

AIR TEMPERATURE

The temperature of air varies in different parts of the day and also in the different seasons. The factors which influence the temperature are altitude of the place, latitude, direction of wind and proximity to sea. The temperature of the ground surface is always higher than that of the air.

MEASUREMENT

Thermometers are instruments used for measuring temperature. Mercury thermometers are widely used, as mercury boils at a high temperature, has a regular expansion and its level can be easily seen. Alcohol thermometers are also used. Alcohol has the advantage of not solidifying even at the lowest known temperature. The essential conditions for the use of the thermometers are that:- (1) the air should have free access to the bulbs of the thermometers and (2) the thermometer should be protected against radiant heat. These conditions are fulfilled by mounting the thermometers on a special approved screen called the "Stevenson Screen" which is used in all the meteorological observatories in India.

Dry bulb thermometer

This is an ordinary thermometer which measures the air temperature. For accurate readings, it is mounted on the "Stevenson Screen" at a height of 1.20 to 1.80 m above the ground level. The screen protects against radiant heat, direct sun and rain.

Wet bulb thermometer

The wet bulb thermometer is precisely the same as the dry bulb thermometer excepting that the bulb is kept wet by a moist cloth fed by water from a bottle through a wick. The evaporation of water from the moist cloth lowers the temperature of the mercury. The wet bulb thermometer therefore shows a lower temperature than the dry bulb thermometer. The drier the air, the lower the wet bulb reading. If the wet and dry bulb thermometers record the same temperature, it means that the air is completely saturated with moisture, which is rare.

Maximum thermometer

This is a mercury thermometer so designed that there is a very fine constriction near the neck of the bulb. When the temperature rises, mercury expands; when the temperature falls, mercury cannot get back into the bulb. The end of the mercury thread at the distal end gives the maximum temperature reached. The thermometer is set each time by swinging briskly when the mercury retreats into the bulb.

Minimum thermometer

This is a mercury thermometer so designed that there is a very fine constriction near the neck of the bulb. When the temperature falls, the spirit drags the index towards the bulb end; when the temperature rises, the spirit expands and runs past the index.

Six's maximum and minimum thermometer

This is combination of the maximum and minimum thermometers. This instrument is not used in the Indian Meteorological Observatories.

Globe thermometer

The globe thermometer is used for the direct measurement of the mean radiant temperature of the surroundings. The instrument consists of a hollow copper bulb 6 inches (15 cm) in diameter and is coated on the outside with matte black paint which absorbs the radiant heat from the surrounding objects. A specially calibrated mercury thermometer is inserted, with its bulb at the centre of the globe (Fig. 1). The globe thermometer registers a higher temperature than the ordinary air temperature thermometer because it is affected both by the air temperature and radiant heat. The difference between the globe thermometer temperature and that of the ordinary dry bulb is a measure of the radiant heat. The globe thermometer is also influenced by the velocity of air movement. The standard globe instrument reaches equilibrium with its environment in 15 to 20 minutes. A modified form of globe thermometer has been
developed by Helon and Crockford, which reaches equilibrium in about half this time, i.e., 8 to 10 minutes. The modified globe is made up from lighter gauge metal than the standard type, i.e., half the gauge and it is also provided with an internal air stirring mechanism consisting of a small fan driven by a miniature 6 volt motor (4).

Wet globe thermometer (5)

This instrument is designed for environmental heat measurement. It consists of a dial thermometer with the wet sensing portion enclosed by a blackened copper sphere that is completely covered with wet black cloth. The Wet Globe exchanges heat with the surroundings by conduction, convection, evaporation and radiation similar to the way a perspiring man does, so the equilibrium temperature of the globe provides a comprehensive measure of the cooling capacity of the work environment (5).

Silvered thermometer

The bright metallic surface reflects as much of the incident radiant heat as possible. This gives a more accurate reading of the air temperature.

Kata thermometer

The word "kata" is a Greek word meaning "down". The Kata thermometer (Fig. 2) is an alcohol thermometer with a glass bulb 4 cm long and 1.8 cm in diameter. The readings on the stem are marked from 100 deg. to 95 deg.F. Two instruments are used, the bulb of one is covered with a wet muslin cloth, the other dry. Before taking the readings, the bulbs are immersed in hot water to warm them slightly above 130 deg.F, when the alcohol rises into a small reservoir at the top of the instrument. After the bulb of the dry Kata is wiped dry. Then both the instruments are suspended in air at the point of observation. The time in seconds required for the spirit to fall from 100 deg. to 95 deg.F is noted with a stop watch. This is repeated at least 4 times. The first reading is discarded and the average of the last three is taken. The length of time depends upon the "cooling power" of the air. Each Kata has a "factor" called the Kata Factor marked on the stem. This factor is determined for each instrument by the manufacturer. This factor, divided by the average cooling time gives the rate of cooling in milliliters per sq. centimetre per second. The Kata thermometer was originally devised for measuring the "cooling power" of the air. A dry Kata reading is 96 and above, and a wet Kata reading of 20 and above were regarded as indices of thermal comfort. The Kata thermometer is now largely used as an instrument for recording low air velocities rather than the cooling power of the air.

Kata thermometers are available to cover the following 5 deg.F cooling ranges: (1) The standard Kata – cooling range between 100 deg. – 95 deg.F; (2) the High Temperature Kata – cooling range between 130 deg. – 125 deg.F and (3) the Extra High Temperature Kata – cooling range between 150 deg. – 145 deg.F. In tropical countries, the atmospheric temperature may be well above 100 deg.F when the standard Kata cannot be used, but the other instruments can be used. The three types of Kata are readily distinguished by the colour of the alcohol. The standard Kata is coloured red; the high temperature instrument, dark blue; and the extra high instrument magenta. Kata thermometers have silvered bulbs to reduce the errors due to radiation.

Heat stress indices (6, 7)

Heat stress is the burden or load of heat that must be dissipated if the body is to remain in thermal equilibrium. The factors which influence heat stress are metabolic rate, air temperature, humidity, air movement and radiant temperature. The amount of heat gained by the body must be equalized by the amount of heat lost from it.

Many heat stress indices have been devised, but none is adequate to be valid in all possible complexities of work rate, air temperature, air movement, etc. These include: Equitothermal Comfort Index, Heat Stress Index, and Predicted Four Hour Sweat Rate (P.H.S.R.). (a) Equitothermal comfort index: This defines the temperature at which the sweating rate of an individual man is equivalent physiologically to the climate under consideration. (b) Heat stress index: This takes into consideration the metabolic rate and the principal channels of heat exchange between the human body and the environment. The heat stress index represents the percentage of the effective cooling capacity of an average man. Nomograms have been prepared from which the value of the heat stress index could be easily calculated. An interpretation of the HSI values are as follows below:

0 ....... No thermal stress
10-30 ....... Moderate to mild heat strain
40-60 ....... Severe heat strain
70-90 ....... Very severe heat strain
100 ....... Upper limit of heat tolerance

(c) Predicted four hour sweat rate: The rate at which a man sweats is a good index of the heat stress to which he is subjected. A sweat rate of 4.5 litres in 4 hours is the upper limit of tolerance in health for work in hot environment. A sweat rate of 2.5 litres in 4 hours is considered optimal for a working man. P.H.S.R. is applicable only in the situation where sweating occurs.

Effects of heat stress

As many as 14 disorders resulting from exposure to heat have been recognized and documented (8). The important ones are: (1) HEAT STROKE: This is attributed to failure of the heat regulating mechanism. It is characterized by very high body temperature which may rise to 110°F (43.3°C) and profound disturbances including delirium, convulsions and partial or complete loss of consciousness. The skin is dry and hot. Classically, sweating is absent or diminished, but
many victims of clear-cut heat stroke perish profusely. The outcome is often fatal, even when patients are brought quickly to medical attention; death/case ratios of 40 per cent or more have been reported. The treatment consists of rapidly cooling the body in ice water bath till the rectal temperature falls below 102°F (38.9°C). The rectal temperature should be monitored continuously, both to monitor the efficacy of hypothermia treatment and to guard against the development of clinically significant hypothermia, which can occur if cooling is continued too long. Further treatment is supportive and directed towards the many potential complications of hyperthermia, Hypovolaemia, hyperkaIaemia, hyponatremia, Hypocalcaemia and bleeding diathesis may require intensive supportive treatment. The patient should be kept in bed for several days until the temperature control becomes stable. (2) HEAT HYPERPYREXIA: This is attributed to impaired functioning of the heat-regulating mechanism without characteristic features of heat stroke. It is arbitrarily defined as a temperature above 106°F (41°C). It may proceed to heat stroke. (3) HEAT EXHAUSTION: Unlike heat stroke, heat exhaustion is not because of failure of thermoregulation. It is a milder illness than heat stroke and is caused primarily by the imbalance or inadequate replacement of water and salts lost in perspiration due to thermal stress. Heat exhaustion typically occurs after several days of high temperature. Body temperature may be normal or moderately elevated, but it is uncommon to exceed 102°F (38.9°C). The symptoms, primarily dizziness, weakness and fatigue, are those of circulatory collapse. It may be severe enough to require hospitalization, especially in elderly patients. Treatment is directed towards normalizing fluid and electrolyte balance. (4) HEAT CRAMPS: Heat cramps occur in persons who are doing heavy muscular work in high temperature and humidity. There are painful and spasmodic contractions of the skeletal muscles. The cause of heat cramps is loss of sodium and chloride in the blood. (5) HEAT SYNCOPE: This is a common ill-effect of heat. In its milder form, the person standing in the sun becomes pale, his blood pressure falls and he collapses suddenly. There is practically no rise in body temperature. The condition results from pooling of blood in lower limbs due to dilatation of blood vessels, with the result that the amount of blood returning to the heart is reduced, which in turn is responsible for lowering of blood pressure and lack of blood supply to the brain. This condition is quite common among soldiers when they are standing for parades in the sun (10). Treatment is quite simple. The patient should be made to lie in the shade with the head slightly down; recovery usually comes within 5 to 10 minutes.

PREVENTIVE MEASURES
The ill effects of high temperature may be prevented by observing the following precautions: (1) REPLACEMENT OF WATER: Persons working under conditions of high temperature and humidity should be encouraged to drink cool water. It has been found in India that a man doing hard work in the sun requires about one litre of water per hour. For a sedentary worker, the requirement is nearly half this quantity. There is a widespread belief that extra salt intake during the summer helps prevent the ill-effects of heat. Studies have shown that the normal intake of salt in the Indian diet is far more than is actually needed. Further, salt losses through sweat are small since the concentration of salt in sweat is considerably low. Therefore, there is no need to add salt to water. However, extra salt is needed by acclimatized persons during the first ten days of their exposure to heat (10). (2) REGULATION OF WORK: The duration of exposure to a hot environment should be cut down. There should be periods of rest between intense work. If signs, such as headache and dizziness appear, the person should be removed to a cooler environment, and the necessary treatment given. (3) CLOTHING: The clothing worn should be light, loose and of light colours. (4) PROTECTIVE DEVICES: Protective goggles, shields and helmets are helpful. (5) WORK ENVIRONMENT: Control of the temperature and humidity in the work environment may be controlled by proper ventilation and air-conditioning.

Effects of cold stress
Injury due to cold may be general or local. In general cold injury (hypothermia), the individual is said to be suffering from exposure to cold. This is characterized by numbness, loss of sensation, muscular weakness, desire for sleep, coma and death. Local cold injury may occur at temperatures above freezing (wet-cold conditions) as in immersion or trench foot. At temperatures below freezing (dry-cold conditions) frostbite occurs; the tissues freeze and ice crystals form in between the cells (11). Frostbite is common at high altitudes. It is extremely important to dress for the temperature with which the part will be in contact. The affected part should be warmed using water at 44 deg. C. Warming should last about 20 minutes at a time. Intake of hot fluids promotes general rewarming.

Global warming
Emission of greenhouse gases into the atmosphere have been increasing ever since the beginning of the industrial revolution. A major component of emission of carbon dioxide is from the combustion of fossil fuels. It is generally considered to be an ill-effect of global warming of about 3°C in the average global surface temperature by the year 2030, a rise in the sea level of 0.1–0.3 metres by 2050, climate changes in the occurrence of extreme climatic events such as cyclones, heatwaves and droughts (12). The temperature rise could overwhelm the capacity of many species to adapt. A change of this magnitude would affect local, regional and global ecosystem, sea levels and ocean currents, prevailing winds, fresh water supplies, agriculture, forests, fisheries, industry, transport, urban planning, demographics and human health. Some effects are mutually reinforcing, so a small additional change in the existing trend could have massive consequences, in accordance with the mathematics of catastrophe theory (13). Changes in the configuration of jet streams, prevailing winds and ocean currents could also alter the distribution of rainfall in many regions, making some wetter, others drier. The summers are becoming hotter. Temperate zone warming induces a decline in soil moisture that impacts grain production. This will also change the distribution of vegetation. The distribution of vector diseases of vector will change. The “heat island” phenomenon that makes cities warmer than surrounding rural areas will lead to longer and more severe heat waves than we are accustomed to now (13).

HUMIDITY
Humidity or moisture is always present in the atmosphere. The amount of moisture which air can hold depends upon its temperature. If the air is cooled, the excessive moisture precipitates for the particular temperature. This is called Dew Point. Humidity may be expressed as absolute humidity or relative humidity.
(a) ABSOLUTE HUMIDITY is the weight of water vapour in a unit volume of air. It is expressed as grammes per kilogram or grammes per cubic metre of air.

(b) RELATIVE HUMIDITY: Relative humidity is the most common way of describing atmospheric moisture. It does not indicate the actual amount of water vapour in the air, instead, it tells us how close the air is to being saturated. The relative humidity (RH) is the ratio of the amount of water vapour actually present to the maximum amount of water vapour required for saturation at that particular temperature (and pressure). It is the ratio of the air's water vapor content to its capacity, thus:

\[ RH = \frac{\text{Water vapor content}}{\text{Water vapor capacity}} \]

It can also be expressed as:

\[ RH = \frac{\text{Actual vapor pressure}}{\text{Saturation vapor pressure}} \times 100 \text{ per cent} \]

Relative humidity is given as a per cent. Air with a 50 per cent RH actually contains one-half the amount required for saturation. Air with a RH greater than 100 per cent is said to be supersaturated. A change in RH can be brought about in two ways:

(a) by changing the air's water vapor content; and (b) by changing the air's temperature with a constant amount of water vapor, cooling the air raises the RH and warming the air lowers it (14).

Very low RH in the house can have an adverse effect on things living inside & including house plants. Very low RH causes rapid evaporation of moisture from exposed skin causing crack, dry skin, itch. It also irrates mucous membranes in the nose and throat, causing an itchy throat. Dry nasal passages permit inhaling dust into the lung causing persistent infection. The remedy for most of these problems is to increase the RH.

(c) DRY POINT: It represents the temperature to which air would have to be cooled (with no change in air pressure or moisture content) for saturation to occur. The dew point is determined with respect to a flat surface of ice; it is called frost point. The dew point is an important measurement used to predict the formation of dew, frost, fog and even, minimum temperature. High dew point indicate high water vapor content; and low dew point indicate low water vapor content.

Measurement

There are several instruments which may be used for measuring humidity. The ones commonly used are described below:

DRY AND WET BULB HYGROMETER

This is the most widely used instrument for measuring humidity. The instrument consists of two similar thermometers – a dry bulb thermometer and a wet bulb thermometer, which are mounted side by side on a stand. The dry bulb measures the air temperature (DBT). The bulb of the second one is covered with a gauge or wick and is kept moist. The wet bulb temperature (WBT) is usually lower than the DBT. If both the readings are the same, it indicates that the atmosphere is 100 per cent saturated with moisture, which never occurs in reality. After obtaining the readings of the dry and wet bulb thermometers, the corresponding RH can be found from specially constructed psychrometric charts or slide rule. Humidity values are high in early morning and are near the minimum value in the afternoon at about 15.00 hours. For accurate readings of the wet bulb thermometer, the air should pass over the bulb with a speed of about 800 ft/min (5 m/sec). The sling psychrometer (described below) achieves this when rotated rapidly.

SLING PSYCHROMETER

The sling or whirling psychrometer (Fig. 3) consists of 2 mercury thermometers (wet and dry) mounted side by side, on a suitable wooden frame, and provided with a handle for rotating the instrument. The underlying principle is that by rotating, the bulbs are exposed to air at a definite velocity. The wet bulb is first moistened with distilled water and the instrument is whirled or rotated standing with the back to the sun, for about 15 seconds at the rate of 4 revolutions per second, so as to obtain the desirable air speed of about 5 metres per second. The reading of the wet bulb is then noted. The instrument is again whirled for about 10 seconds and the wet bulb reading is noted. This is repeated several times till 2 successive readings of the wet bulb are identical. The reading of the dry bulb is then noted. By use of suitable tables or charts, the relative humidity of the air may be obtained from the readings of the psychrometer.

ASSMANN PSYCHROMETER

This is a portable instrument specially designed to give accurate measurements of the wet and dry bulb temperature of the air. In this instrument, air is drawn at a speed higher than 5 metres per second by a clock-work fan. The bulbs of the thermometer are protected from the effects of solar radiation so that the instrument can be used even in strong sunshine.

PRECIPITATION

This is the most widely used term for rain, snow, hail, dew and frost – that is, all forms of water precipitated from the atmosphere. It is measured by rain-gauges. The rain-gauge prescribed by the Government of India for use at rainfall measuring stations in India is known as the "Symon's Rain-gauge". The funnel for receiving the rainfall has a diameter of 5 inches. Great care is exercised in selecting a suitable site for the erection of rain-gauge. The Rain-gauge should be set on a level ground, away from trees, buildings, or other obstructions. The rule which must be strictly adhered to in the erection of a Rain-gauge is that its rim should be exactly horizontal, and one foot above the ground level, the instrument having been fixed in a_masonry or concrete foundation. The rainfall is measured in millimeters per a time unit (mm/day, mm/month).

FIG 3
Sling psychrometer
AIR VELOCITY

Air velocity

The air velocity is measured by an instrument called the anemometer. It consists of four hemispherical cups, attached to the ends of 2 crossed metal arms. There is a vertical spindle which is attached to the ‘anemometer box’. The velocity of the wind is indicated on a counter called the cyclogram, placed in the anemometer box.

Wind velocities are normally recorded in open flat country at a height of 10 m. Velocities are measured in metres per second (m/s). When the wind speed is 0.5 m/s, it is described as complete calm with smoke rising vertically; when it is 3.3 m/s, it is described as slight breeze with leaves rustling; when it is 10 m/s, it is described as strong wind with larger branches of trees moving; when it is 15-20 m/s, it is called storm; when it is 25-30 m/s, it is called gale; and over 30-50 m/s, it is called hurricane.

KATA THERMOMETER: The Kata thermometer is quite sensitive to slight air movements. It can record air velocities as low as 10 feet per minute. This instrument has already been described.

Wind direction

The wind direction is observed by an instrument called the wind vane. There is an arrow which turns freely about a vertical axis. The wind vane is erected at a height of 10 m above ground level. If the arrow is motionless for 3 minutes, the wind is described as ‘calm’. The wind direction may also be noted by letting off bits of paper in the air, which gives the approximate direction. Directions are grouped into 4 main categories: (N, E, S, and W) and 8 or 16 sub-categories.

Clouds and weather observations

In all meteorological stations, clouds are observed for their form, amount, direction and height. Such observations give an insight into the sequence of weather in the particular locality. From the state of the sky and evolution of clouds, weather is described as fine weather, fair weather, unsettled weather, bad weather and thunderous sky. Meteorological satellites are now being used for automatic picture taking to give an idea of the clouds. The satellites can also measure temperature and humidity in the atmosphere.

HOUSING

6. encourages personal and community development, promotes social relationships, reflects a regard for ecological principles, and by these means promotes mental health.

Housing standards

With the broadening concept of housing, the concept of housing standards has also changed. The standards are no longer confined to narrow health criteria like per capita space and floor space. Social and economic characteristics such as family income, family size and composition, standard of living, lifestyle, stage in life cycle, education, and cultural factors must be taken into consideration in determining housing standards. Because of cultural diversity and other factors such as climate and social traditions, standards of housing must vary from country to country and from region to region. In short, there cannot be rigid, universal standards.

However, minimum standards are still maintained by building regulations, the aim being improvement of housing and environmental conditions for the majority of families within the limits set by available resources and objectives. The standards in India are those recommended by the EHC (1947). These are as below:

SITE: (a) The site should be elevated from its surroundings so that it is not subject to flooding during rains (b) the site should have an independent access to a street of adequate width (c) it should be away from the breeding places of mosquitoes and flies (d) it should be away from nuisances such as dust, smoke, smell, excessive noise and traffic (e) it should be in pleasing surroundings (f) the soil should be dry and safe for founding the structure and should be well drained. “Made-soil”, i.e., ground that is levelled by dumping refuse is very unsatisfactory for building purposes for at least 20 to 25 years. The subsoil water should be below 10 feet (3 metres).

SET BACK: For proper lighting and ventilation, there should be an open space all round the house – this is called “set back”. In rural areas it is recommended that the built-up area should not exceed one-third of the total area; in urban areas where land is costly, the built-up area may be up to two-thirds. The set back should be such that there is no obstruction to lighting and ventilation.

FLOOR: The floor should be pucca and satisfy the following criteria: (a) it should be impermeable so that it can be easily cleaned and kept clean and dry. Mud floors tend to break up and cause dust; they are not recommended, (b) the floor should be smooth and free from cracks and crevices to prevent the breeding of insects and harbourage of dust, (c) the floors should be damp-proof, (d) the height of the plinth should be 2 to 3 feet (0.6 to 1 metre).

WALLS: The walls should be (a) reasonably strong (b) should have a low heat capacity i.e., should not absorb heat and conduct the same (c) weather resistant (d) unsuitable for harbourage of rats and vermin (e) not easily damaged and (f) smooth. These standards can be attained by 9-inch brick-wall plastered smooth and coloured cream or white.

ROOF: The height of the roof should not be less than 10 feet (3 m) in the absence of air-conditioning for comfort. The roof should have a low heat transmittance coefficient.

ROOMS: The number of living rooms should not be less than two, at least one of which can be closed for security. The other may be open on one side if that side is a private courtyard. The number and area of rooms should be with regard to size of family, so that the recommended floor space per person may be made available.

FLOOR AREA: The floor area of a living room should be at least 120 sq. ft. (12 sq. m.) for occupancy by more than one person and at least 100 sq. ft. (10 sq. m.) for occupancy by a single person. The floor area available in living rooms per person should not be less than 50 sq.ft; the optimum is 100 sq. ft.

CUBIC SPACE: Unless means are provided for mechanical replacement of air the height of rooms should be such as to give an air space of at least 500 c.f. per capita, preferably 1000 c.f.

WINDOWS: (a) Unless mechanical ventilation and artificial lighting are provided, every living room should be provided with at least 2 windows, and at least one of them should open directly on to an open space, (b) the windows should be placed at a height of not more than 3 feet (1 m) above the ground in living rooms (c) window area should be 1/5th of the floor area. Doors and windows combined should have 2/5th the floor area.

LIGHTING: The daylight factor should exceed 1 per cent over half the floor area.

KITCHEN: Every dwelling house must have a separate kitchen. The kitchen must be protected against dust and smoke; adequately lighted; provided with arrangements for storing food, fuel and provisions; provided with water supply; provided with a sink for washing utensils and fitted with proper drainage. The floor of the kitchen must be impervious.

PRIVY: A sanitary privy is a MUST in every house, belonging exclusively to it and readily accessible. In the more overcrowded areas of the city, the majority of dwelling units are equipped with water carriage systems.

GARBAGE AND REFUSE: These should be removed from the dwelling at least daily and disposed off in a sanitary manner.

BATHING AND WASHING: The house should have facilities for bathing and washing belonging exclusively to it and providing proper privacy.

WATER SUPPLY: The house should have a safe and adequate water supply available at all times.

Rural housing

In rural areas, the “approved” standards may be lower than in towns. The following minimum standards have been suggested: (1) there should be at least two living rooms (2) ample verandah space may be provided (3) the built-up area should not exceed one-third of the total area (4) there should be a separate kitchen with a paved sink or platform for washing utensils (5) the house should be provided with a sanitary latrine (6) the window area should be at least 10 per cent of the floor area (7) there should be a sanitary well or a tube well within a quarter of a mile from the house (8) it is insanitary to keep cattle and livestock in dwelling houses. Cattle sheds should be at least 25 feet away from dwelling houses. A cattle shed should be open on all sides; an area 8 ft. x 4 ft. is sufficient for each head of cattle (9) there should be adequate arrangement for the disposal of waste water, refuse and garbage (10).

Housing and health

Housing is part of the total environment of man and
being a part, it is to some extent responsible for the status of man's health and well-being. It is difficult, however, to demonstrate the specific, cause-and-effect relationship because housing embraces so many facets of environment. By deductive reasoning, a strong relationship can be established between poor housing and the following conditions:

1. **Respiratory Infections**: Common cold, tuberculosis, influenza, diphtheria, bronchitis, measles, whooping cough, etc.

2. **Skin Infections**: Scabies, ringworm, impetigo, leprosy.

3. **Bacterial Infection**: Plague.

4. **Arthropods**: Houseflies, mosquitoes, fleas and bugs.

5. **Accidents**: A substantial proportion of house accidents are caused by some defect in the home and its environment.

6. **Morbidity and Mortality**: High morbidity and mortality rates are observed where housing conditions are sub-standard.

7. **Psychosocial Effects**: These effects must not be overlooked. The sense of isolation felt by persons living in the upper floors of high buildings is now well known to have harmful effects. Often, also, people living in densely populated urban areas feel a similar sense of isolation which may lead to neurosis and behaviour disorders.

If the definition of health given by WHO is applied, we have also to take into consideration the broader aspects of mental and social well-being of individuals and families, i.e., factors related to satisfaction of physiological, psychological and social needs.

**Overcrowding**

Overcrowding refers to the situation in which more people are living within a single dwelling than there is space for, so that movement is restricted, privacy is excluded, hygiene is impossible, rest and sleep are difficult (1). In general the risks as regards physical health are clear enough – infectious diseases spread rapidly under conditions of overcrowding. The effects on psychosocial health are not so clear-cut, viz. irritability, frustration, lack of sleep, anxiety, violence and mental disorders. Children are said to be more affected. In short, it is a psychosocial stress, leading to unhappiness and very probably to psychosomatic and mental disorders.

Overcrowding is a health problem in human dwellings. It may promote the spread of respiratory infections such as tuberculosis, influenza and diphtheria. High morbidity and mortality rates are observed where housing conditions are substandard. The accepted standards with respect to overcrowding are as below:

- **1 person per room**
  - 1 room: 1 person
  - 2 rooms: 2 persons
  - 3 rooms: 3 persons
  - 4 rooms: 4 persons
  - 5 or more rooms: 5 persons

- **2 or more persons per room**
  - 1 room: 2 persons
  - 2 rooms: 3 persons
  - 3 rooms: 4 persons
  - 4 rooms: 5 persons
  - 5 or more rooms: 6 persons

- **3 or more persons per room**
  - 1 room: 3 persons
  - 2 rooms: 4 persons
  - 3 rooms: 5 persons
  - 4 rooms: 6 persons
  - 5 or more rooms: 7 persons

- **4 or more persons per room**
  - 1 room: 4 persons
  - 2 rooms: 5 persons
  - 3 rooms: 6 persons
  - 4 rooms: 7 persons
  - 5 or more rooms: 8 persons

- **5 or more persons per room**
  - 1 room: 5 persons
  - 2 rooms: 6 persons
  - 3 rooms: 7 persons
  - 4 rooms: 8 persons
  - 5 or more rooms: 9 persons

(1) FLOOR SPACE: The accepted standards are:

- 110 sq. ft. (11 sq. m.) or more: 2 persons
- 90–100 sq. ft. (9–10 sq. m.): 1½ persons
- 70–90 sq. ft. (7–9 sq. m.): 1 person
- 50–70 sq. ft. (5–7 sq. m.): ½ person
- Under 50 sq. ft. (5 sq. m.): nil

A baby under 12 months is not counted; children between 1 and 10 years counted as half a unit.

**SEX SEPARATION**: Overcrowding is considered to exist if 2 persons over 9 years of age, not husband and wife, of opposite sexes are obliged to sleep in the same room.

**Indicators of housing**

In recent years the use of indicators has become widespread for the measurement of quality of life. The indicators for housing may be classified as:

- **Physical**: These are based on floor space, cubic space, room height, persons per room, rooms per dwelling, environmental quality (e.g., air, light, water, noise, sewage disposal, etc).
- **Economic Indicators**: These are cost of the building, rental levels, taxes, expenditure on housing, etc.
- **Social Indicators**: The following were proposed at an inter-regional seminar on the Social Aspects of Housing, organized by the UN in 1973.

(a) Indicators related to prevention of illness:

1. Frequency of illness due to inadequate sewage and garbage collection.
2. Frequency of illness associated with contaminated water source.
3. Frequency of insect borne diseases.
4. Frequency of illness due to overcrowding.
5. Frequency of illness due to accidents.
6. Frequency of illness due to proximity to animals.
7. Access to medical facility.

(b) Indicators related to comfort:

1. Thermal comfort
2. Acoustic comfort
3. Visual comfort
4. Spatial comfort.

(c) Indicators related to mental health and social well-being:

1. Frequency of suicides in the neighbourhood.
2. Neglected and abandoned youth in the neighbourhood.
3. Drug abuse (including alcohol) in the neighbourhood.

**Public policy**

In every country where housing conditions in general are unsatisfactory the need for government intervention has been recognized. The approach to public policy on housing in India is indicated in the Five Year Plans. In 1952, a separate Ministry of Works and Housing was created at the Centre. The Government Housing Programmes consists of two categories – public sector housing and social housing schemes. The former provides mainly for government employees, while the latter attempts to provide assistance particularly to low and middle income groups through various housing schemes. For promoting housing activities, statutory Housing Boards have been established at the state
level. Four organizations, via the National Buildings Organization (NBO), National Buildings Constructions Corporation of India Ltd (NBCC), the Urban Development Corporation (HUDCO) and the Hindustan Housing Factory are functioning under the aegis of the Union Ministry of Urban Development.

According to an assessment by NBO, the housing stock in 1911 was estimated to be 14.1 million in urban areas and 65.4 million in rural areas (total 79.5 million). This increased to 58.2 million in 1971, 116.7 million in 1981 and 148.8 million in 1991 (6). In 2001 census, the total number of houses counted was 249 million and according to 2011 census, the total number of houses counted were 330.6 million. This includes 220.7 million houses in rural areas and 110.1 million houses in urban areas (11). Urban housing crisis has manifested itself in many ways of which the most significant is the growth of slums and squatter settlement. It was estimated that about 48.6 million persons were living in slums in 1990. About 40 per cent of this population was in million-plus cities. The overall rate of construction of new houses recommended by the expert body of the UN is 10 houses per 1000 persons per year (7).

The Eighth and subsequent Five Year Plans have strategy for the National Housing Policy consisting of creating an enabling environment for housing activity, viewed as an important component of the national economy, by eliminating various constraints and providing direct assistance to the specially disadvantaged groups including rural and urban poor household, SC/ST, physically handicapped, widows and single women (6).

House site and construction assistance: The scheme was included in the State Sector as a part of Minimum Needs Programme and formed the core of the rural housing programme during Ninth and subsequent Five Year Plans. This scheme has two components — provision of free house sites and construction assistance with varying proportion of subsidy and loan in different states. Construction assistance is planned to benefit 3.5 million families directly as part of MNP. This is exclusive of other special rural housing programmes intended for specific beneficiaries groups.

Indira Awaas Yojana (IAY): The Indira Awaas Yojana was introduced in 1991. A part of the Rural Landless Employment Guarantee Programme. This type of houses have one room, one kitchen attached with latrine, bathroom and a smokeless chulah (9).

DISPOSAL OF WASTES

Disposal of wastes is now largely the domain of sanitariums and public health engineers. However, health professionals need to have a basic knowledge of the subject since improper disposal of wastes constitutes a health hazard. Further the health professional may be called upon to give advice in some special situations, such as camp sanitation or coping with waste disposal problems when there is a disruption or breakdown of community health services in natural disasters. These aspects are considered in this section.

SOLID WASTES

The term "solid wastes" includes garbage (food wastes) rubbish (paper, plastics, wood, metal, throw-away container, glass), demolition products (bricks, masonry pipes), sewage treatment residue (sludge and solids from the coagulation screening of domestic sewage), dead animals, manure and other discarded material. Strictly speaking it should not contain weather-soil in collection of refuse (3). The output of daily waste depends upon the dietary habits, life styles, living standards and the degree of urbanization and industrialization. The per capita daily solid waste produced range between 0.25 to 2.5 kg in different countries.

Solid waste, if allowed to accumulate, is a health hazard because:

a. it decomposes and favours fly breeding
b. it attracts rodents and vermin
c. the pathogens which may be present in the solid waste may be conveyed back to man's food through flies and dust.
d. there is a possibility of waste and soil pollution, and

e. heaps of refuse present an unsightly appearance in the landscape.

There is a correlation between improper disposal of solid wastes and incidence of vector-borne diseases. Therefore, in all civilized countries, there is an efficient system for its periodic collection, removal and final disposal without risk to health.

Sources of refuse

(1) Refuse that is collected by the street cleaning service or scavenging is called street refuse. It consists of leaves, straw, paper, animal droppings and litter of all kinds.

(2) Refuse that is collected from markets is called market refuse. It contains a large proportion of unfit vegetable and animal matter. (3) Refuse that is collected fromables is called stable litter. It contains mainly animal droppings and left-over animal foods. (4) Industrial refuse comprises a wide variety of wastes ranging from completely inert materials such as calcium carbonate to highly toxic and explosive compounds. (5) Domestic refuse consists of ash, rubbish and garbage. Ash is the residue from fire used for cooking and heating. Rubbish comprises paper, clothing, bits of wood, metal, glass, dust and dirt. Garbage is waste matter arising from the preparation, cooking and consumption of food. It consists of waste food, vegetable peelings and other organic matter. Garbage needs quick removal and disposal because it ferments on storage.
Storage

The first consideration should be given to the proper storage of refuse, while awaiting collection. The galvanized steel dust bins with close-fitting cover is a suitable receptacle for storing refuse. The capacity of a bin will depend upon the number of users and frequency of collection. The output of refuse per capita per day in India is estimated to vary from 1/4 to 1/2 cft. For a family of 5 members, a bin having a capacity of 5/10 or 1/2 cft. would be needed. If collection is done once in 3 days, a bin having a capacity of 1/1 or 2 cft. would be adequate. A recent innovation in the western countries is the "paper sack." Refuse is stored in the paper sack, and the sack itself is removed with the contents for disposal and a new sack is substituted. Public bins: Public bins cater for a larger number of people. They are usually without cover in India because people do not like to touch them. They are kept on a concrete platform raised 2 to 3 inches above ground level to prevent flood water entering the bins. In bigger municipalities, the bins are handled and emptied mechanically by lorries fitted with cranes.

Collection

The method of collection depends upon the funds available. House-to-house collection is by far the best method of collecting refuse. Only at some places in the urban areas this kind of facility is available. In majority of places in India, there is no house-to-house collection system.

People are expected to dump the refuse in the nearest public bin, which is usually not done. Refuse is dispersed all along the street, and some is thrown out in front and around the house. As a result, an army of sweepers is required for sweeping the streets in addition to the gang for collecting the refuse from public bins. The refuse is then transported in refuse collection vehicles to the place of ultimate disposal. Dead animals are directly transported to the place of disposal.

The collection methods normally practised in this country need drastic revision and improvement in the interest of better hygiene. The Environmental Hygiene Committee (1949) recommended that municipalities and other local bodies should arrange for collection of refuse not only from the public bins but also from individual houses (4). A house-to-house collection will result in a simultaneous reduction in the number of public bins (5). The open refuse cart should be abandoned and replaced by enclosed vans. Mechanical transport should be used whenever possible as it is more practical and economical than the 19th century methods. There is a wide variety of refuse collection vehicles of all shapes and sizes. The latest arrival in the western countries is the "Dustless Refuse Collector" which has a totally enclosed body.

Methods of disposal

There is no single method of refuse disposal which is equally suitable in all circumstances. The choice of a particular method is governed by local factors such as cost and availability of land and labour. The principal methods of refuse disposal are:

(a) Dumping
(b) Controlled tipping or sanitary land-fill
(c) Incineration
(d) Composting
(e) Manure pits
(f) Burial.

(a) Dumping

Refuse is dumped in low lying areas partly as a method of reclamation of land but mainly as an easy method of disposal of dry refuse. As a result of wetting the refuse decreases considerably in volume and is converted gradually into humus. Rojakda disposal of its refuse by dumping and the reclaimed land is leased out for cultivation. The drawbacks of open dumping are:

(1) the refuse is exposed to flies and rodents; (2) it is a source of nuisance from the smell and unsightly appearance; (3) the loose refuse is dispersed by the action of the wind; and (4) drainage from the dumpy contributes to the pollution of surface and ground water. A WHO Expert Committee (1967) condemned dumping as "a most insanitary method that creates public health hazards a nuisance, and severe pollution of the environment." Dumping should be outlawed and replaced by sound procedures (6).

(b) Controlled tipping

Controlled tipping or sanitary land-fill is the most satisfactory method of refuse disposal where suitable land is available. It differs from ordinary dumping in that the material is placed in a trench or other prepared area, adequately compacted, and covered with earth at the end of the working day. The term "modulated sanitary landfill" has been applied to those operations where compaction and covering are accomplished once or twice a week (7).

Three methods are used in this operation: the trench method, the ramp method and the area method (7, 8).

(1) The trench method: Where level ground is available, the trench method is usually chosen. A long trench is dug out of 2 to 3 m (6.6 to 9.8 ft.) deep and 1.2 to 1.5 m (4 to 5 ft.) wide, depending upon local conditions. The refuse is compacted and covered with excavated earth. Where compacted refuse is placed in the fill to a depth of 2 m (6.6 ft.), it is estimated that one acre of land per year will be required for 10,090 population (7).

(2) The ramp method: This method is well suited where the terrain is moderately sloping. Some excavation is done to secure the covering material.

(3) The area method: This method is used for filling land depressions, disused quarries and clay pits. The refuse is deposited, packed and consolidated in uniform layers up to 2 to 2.5 m (6.6 to 8 ft.) deep. Each layer is sealed on its exposed surface with a mud cover at least 30 cm (12 inches) thick. Such sealing prevents infiltration by flies and rodents and suppresses the nuisance of smell and dust. This method often has the disadvantage of requiring supplemental earth from outside sources.

Chemical, bacteriological and physical changes occur in buried refuse. The temperature rises to over 60°C within 7 days and kills all the pathogens and hastens the decomposition process. Then it takes 2 to 3 weeks to cool down. Each ton of refuse contains about 28.6 kg (63 lb.) of carbon. The tanning of refuse in water should not be done as it creates a nuisance from odours given off by the decomposition of organic matter. The method of controlled tipping has been revolutionized by mechanization. The bulldozer replaces the tasks of spreading trimming and spreading top soil.

(c) Incineration

Refuse can be disposed of hygienically by burning or
incineration. It is the method of choice where suitable land is not available. Hospital refuse which is particularly dangerous is best disposed of by incineration. Incineration is practised in several of the industrialized countries, particularly in large cities due to lack of suitable land. Incineration is not a popular method in India because the refuse contains a fair proportion of fine ash which makes the burning difficult. A preliminary separation of dirt or ash is necessary. This involves heavy digging and expenditure for the incinerator. Further, disposal of refuse by burning is a loss to the community in terms of the much-needed manure. Burning, therefore, has a limited application in refuse disposal in India.

d) Composting

Composting is a method of combined disposal of refuse and nightsoil or sludge. It is a process of nature whereby organic matter breaks down under bacterial action resulting in the formation of relatively stable humus-like material, called the compost which has considerable manure value for the soil. The principal by-products are carbon dioxide, water and heat. The heat produced during composting, about 60 deg C or higher, over a period of several days, destroys eggs and larvae of flies, weed seeds and pathogenic agents. The end-product – compost – contains few or no disease producing organisms, and is a good soil builder containing small amounts of the major plant nutrients such as nitrates and phosphates (9). The following methods of composting are now used:

(1) Bangalore method (Anaerobic method)
(2) Mechanical composting (Aerobic method)

(1) BANGALORE METHOD (Hot fermentation process)

As a result of investigations carried out under the auspices of the Indian Council of Agricultural Research at the Indian Institute of Science, Bangalore, a system of anaerobic composting, known as Bangalore method (hot fermentation process) has been developed. It has been recommended as a satisfactory method of disposal of town wastes and nightsoil (10).

Trenches are dug 90 cm (3 ft.) deep,1.5 to 2.5 m (5-8 ft.) broad and 4.5 to 10 m (15-30 ft.) long, depending upon the amount of refuse and nightsoil to be disposed of. Depths greater than 90 cm (3 ft.) are not recommended because of slow decomposition. The pits should be located not less than 800 m (1/2 mile) from city limits. The composting procedure is as follows: First a layer of refuse about 15 cm (6 in) thick is spread at the bottom of the trench. Over this, nightsoil is added, corresponding to a thickness of 5 cm (2 in). Then, alternate layers of refuse and nightsoil are added in the proportion of 15 cm (6 in) and 5 cm (2 in) respectively, till the heap rises to 30 cm (1 ft.) above the ground level. The top layer should be of refuse, at least 25 cm (9 in) thickness. Then the heap is covered with excavated earth. 2’ properly laid, a man’s legs will not sink when walking over the compost mass (10).

Within 7 days as a result of bacterial action considerable heat (over 60 deg C) is generated in the compost mass. This intense heat which persists over 2 or 3 weeks, serves to decompose the refuse and nightsoil and to destroy all pathogenic and parasitic organisms. At the end of 4 to 6 months, decomposition is complete and the resulting manure is a well-decomposed, odourless, innocuous material of high manure value ready for application to the land. The Environmental Hygiene Committee (1949) did not recommend composting by municipalities with a population of over 100,000 (4). Bigger municipalities should install underground sewers to transport human excreta.

(2) MECHANICAL COMPOSTING

Another method of composting known as ‘Mechanical composting’ in some countries, the compost is literally manufactured on a large scale by processing raw materials and turning out a finished product. The refuse is first cleared of salvageable materials such as rags, boxes, metal, glass and items which are likely to interfere with the grinding operation. It is then pulverised in a pulverising equipment in order to reduce the size of articles to less than 2 inches. The pulverised refuse is then mixed with sewage, sludge or nightsoil in a rotating machine and incubated. The factors which are controlled is the operation are a certain carbon-nitrogen ratio, temperature, moisture, pH and aeration. The entire process of composting is complete in 4 to 6 weeks. This method of composting is in vogue in some of the developed countries, e.g., Holland, Germany, Switzerland, Israel. The Government of India is considering the installation of mechanical composting plants in selected cities. Cities such as Delhi, Nagpur, Mumbai, Chennai, Bhopal, Allahabad, Hyderbad, Lucknow and Kanpur have offered to join the Government for setting up pilot plants for mechanical composting (3).

(e) Manure pits

In rural areas in India, there is no system for collection and disposal of refuse. Refuse is thrown around the houses indiscriminately resulting in gross pollution of the soil. The problem of refuse disposal in rural areas can be solved by digging ‘manure pits’ by the individual householders. The garbage, cattle dung, straw, and leaves should be dumped into the manure pits and covered with earth after each day’s dumping. Two such pits would be needed, when one is closed, the other will be in use. In 5 to 6 month’s time, the refuse is converted into manure which can be returned to the field. This method of refuse disposal is effective and relatively simple in rural communities.

(f) Burial

This method is suitable for small camps. A trench 1.5 m wide and 2 m deep is excavated, and at the end of each day the refuse is covered with 20 to 30 cm of earth. When the level in the trench is 40 cm from ground level, the trench is filled with earth and compacted, and a new trench is dug out. The contents may be taken out after 4 to 6 months and used on the fields. If the trench is 1 m in length for every 200 persons, it will be filled in about one week (8).

Public education

Refuse disposal cannot be solved without public education. People have very little interest in cleanliness outside their homes. Many municipalities and corporations usually look for the cheapest solution, especially in regard to refusal disposal. What is needed is public education on these matters, in the form of talks, conferences, lectures, pamphlets, newspapers, broadcasting, films etc. Police enforcement of the laws may also be needed at times.

Economics and finance

If refuse disposal is to be carried out efficiently, hygienically and economically, heavy capital outlay will be needed whatever system of disposal is adopted. In the highly
EXCRETA DISPOSAL

Public health importance

Human excreta is a source of infection. It is an important cause of environmental pollution. Every society has a responsibility for its safe removal and disposal so that it does not constitute a threat to public health. The HEALTH HAZARDS of improper excreta disposal are: (1) soil pollution, (2) water pollution, (3) contamination of foods, and (4) propagation of flies. The resulting diseases are typhoid and paratyphoid fevers, dysentery, diarrhoeas, cholera, hookworm disease, ascariasis, viral hepatitis and similar other intestinal infections and parasitic infestations. These diseases are not only a burden on the community in terms of sickness, mortality and a low expectation of life, but a basic deterrent to social and economic progress. Proper disposal of human excreta, therefore, is a fundamental environmental health service without which there cannot be any improvement in the state of community health.

Extent of the problem in India

In many areas of the world, including India, excreta disposal is a problem of grave importance. Nearly 70 per cent of India’s population live in rural areas and the majority of them “go to the fields” for defecation and thereby pollute the environment with human excrement.

Statistics indicate that the intestinal group of diseases claim about 5 million lives every year while another 50 million people suffer from these infections (1). Surveys carried out in the community development block areas in Andhra Pradesh, Assam, Bihar, Madhya Pradesh, Manipur, Orissa, Rajasthan and West Bengal show that the enteric group of fevers is very common in rural areas (2).

Hookworm disease is also known to be highly prevalent: about 45 million people are estimated to be infested with hookworms (3). The solution to the problem is only through hygienic disposal of human excreta which is the cornerstone of all public health services.

How disease is carried from excreta

Let us consider how the faecal-borne diseases are transmitted to a new host. The human excreta of a sick person or a carrier of disease is the main focus of infection. It contains the disease agent which is transmitted in a new host through various channels: (1) water, (2) soil, (3) flies, (4) soil and (5) food. These events are as shown in Fig. 1.

Sanitation barrier

Community medicine aims at breaking the disease cycle at vulnerable points. The disease cycle (Fig. 1) may be broken at various levels: segregation of faeces, protection of water supplies, protection of foods, personal hygiene and control of flies. Of these, the most effective step would be to segregate the faeces and arrange for its proper disposal so that the disease agent cannot reach the new host, directly or indirectly. Fig. 2 shows the segregation of the excreta by imposing a barrier called the “sanitation barrier”. In simple terms, this barrier can be provided by a ‘sanitary latrine’ and a disposal pit. The more elaborate schemes envisage installation of a sewage system and sewage treatment plants.

![FIG. 1](image1)

**FIG. 1** Transmission of faecal-borne diseases (13)

![FIG. 2](image2)

**FIG. 2** Sanitation barrier to transmission of faecal-borne diseases (13)
Methods of excreta disposal

There are a number of methods of excreta disposal. Some are applicable to unsewered areas, and some to sewer areas. A classification and description of the various methods of excreta disposal is given below:

I. Unsewered areas

1. SERVICE TYPE Latrines (CONSERVANCY SYSTEM)
   Nightsoil is collected from pail or bucket type of latrines by human agency, and later disposed of by burying or composting.

2. NON-SERVICE TYPE (SANITARY LATRINES)
   (a) Bore hole latrine
   (b) Dug well or pit latrine
   (c) Water-seal type of latrines
      (i) P.R.A.I. type
      (ii) R.C.A. type
   (d) Sulabh Shauchalaya
   (e) Septic tank
   (f) Aqua privy

3. LATRINES SUITABLE FOR CAMPS AND TEMPORARY USE
   (a) Shallow trench latrine
   (b) Deep trench latrine
   (c) Pit latrine
   (d) Bore hole latrine

II. Sewered areas

1. WATER–CARRIAGE SYSTEM AND SEWAGE TREATMENT
   (a) Primary treatment
      Screening
      Removal of grit
      Plain sedimentation
   (b) Secondary treatment
      Trickling filters
      Activated sludge process
   (c) Other methods
      (i) Sea outfall
      (ii) Roer outfall
      (iii) Sewage farming
      (iv) Oxidation ponds

I. Excreta disposal in unsewered areas

1. SERVICE TYPE (CONSERVANCY SYSTEM)
   The collection and removal of nightsoil from bucket or pail latrines by human agency is called the service type or conservancy system, and the latrines are called service latrines. The nightsoil is transported in “nightsoil carts” to the place of final disposal, where it is disposed off by (i) composting or (ii) burial in shallow trenches. Service latrines are a source of filth and unsanitation. They have all the drawbacks and faults which tend to perpetuate the disease cycle of faecal-borne diseases in the community (Fig. 3). The night soil is exposed to flies; there is always the possibility of water and soil pollution. The buckets and pans are subject to corrosion and require frequent replacement.

The emptying operation of the buckets is not always satisfactory. It is also difficult to recruit adequate staff needed for the collection of nightsoil. If the sweepers go on strike, the entire machinery collapses with dire consequences to public health. Furthermore, the employment of human labour for the collection of nightsoil is not consistent with human dignity and is no longer pardonable. The Environmental Hygiene Committee (1949) therefore, recommended that in unsewered areas the service latrines should be replaced by sanitary latrines which require no service, and in which excreta can be disposed off at the site of the latrine in a hygienic manner (4).

2. NON-SERVICE TYPE OF LATRINES (SANITARY LATRINES)
   A sanitary latrine is one which fulfils the following criteria:
   (1) Excreta should not contaminate the ground or surface water
   (2) Excreta should not pollute the soil
   (3) Excreta should not be accessible to flies, rodents, animals (pigs, dogs, cattle, etc.) and other vehicles of transmission
   (4) Excreta should not create a nuisance due to odour or unsightly appearance.
   A brief description of some of the well-known types of sanitary latrines is given below:

BORE HOLE LATRINE

The bore hole latrine is the forerunner of the non-service type of latrines in this country. It was first introduced by the Rockefeller foundation during 1930’s in campaigns of hookworm control. The latrine consists of a circular hole 30 to 40 cm (12–16 in.) in diameter, dug vertically into the ground to a depth of 4 to 8 m (13–26 ft.); most commonly 6 m (20 ft.). A special equipment known as auger is required to dig a bore hole. In loose and sandy soils, the hole is lined with bamboo matting or earthen–ware rings to prevent caving in of the soil (1). A concrete squating plate with a central opening and foot rests is placed over the hole. A suitable enclosure is put up to provide privacy. For a family of 5 or 6 people, a bore hole of the above description serves well for over a year. Bore hole is essentially a family type of installation and is not recommended as a public convenience because of its small capacity. When the contents of the bore hole reach within 50 cm (20 in.) of the ground level, the squatting plate is removed and the hole is closed with earth.

![FIG. 3 Bore hole latrine](image-url)
A new hole is dug and similarly used. The nightsoil undergoes purification by anaerobic digestion and is eventually converted into a harmless mass. The amount of sludge that accumulates has been estimated to amount to 2.1 to 7.3 cubic feet per 1,000 users per day (2). The merits of a bore hole latrine are: (1) there is no need for the services of a sweeper for daily removal of nightsoil, (2) the pit is dark and unsuitable for fly breeding, (3) if located 15 m (50 ft) away from a source of water supply, there should be no danger of water pollution. In spite of these merits, bore hole latrines are not considered a very suitable type of latrine today. The reasons are: (a) the bore hole fills up rapidly because of its small capacity, (b) a special equipment, the auger, is required for its construction which may not be readily available, (c) in many places, the subsoil is high and the soil loose, with the result it may be difficult to dig a hole deeper than 3 m (10 ft). The bore hole latrine is therefore, not very much in use today. It has been superseded by better innovations.

**DUG WELL LATRINE**

Dug well latrine or pit latrine (Fig. 4) was first introduced in Singhur, West Bengal in 1949–1950 (1). It is an improvement over the bore hole latrine. A circular pit about 75 cm (30 in.) in diameter and 3 to 3.5 m (10–12 ft.) deep is dug into the ground for the reception of the nightsoil. In sandy soil, the depth of the pit may be reduced to 1.5 to 2 m (6–7 ft.). The pit may be lined with pottery rings, and as many rings as necessary to prevent caving in of the soil may be used. A concrete squatting plate is placed on the top of the pit, and the latrine is enclosed with a superstructure. The advantages of this type of latrine are: (1) it is easy to construct and no special equipment such as an auger is needed to dig the pit, (2) the pit has a longer life than the bore hole because of greater cubic capacity. A pit 75 cm (30 in.) diameter and 3 to 3.5 m (10–12 ft.) deep will last for about 5 years for a family of 4 to 5 persons. When the pit is filled up, a new pit is constructed. The action of the dug well latrine is the same as in the bore hole latrine, i.e., anaerobic digestion.

**WATER SEAL LATRINE**

A further improvement in the designing of sanitary latrines for rural families is the hand-flushed “water seal” type of latrine (Fig. 5). Here, the squatting plate is fitted with a water seal. The water seal performs two important functions: (1) it prevents access by flies. That is, the nightsoil is sealed off from flies, by a small depth of water contained in a bent pipe called the trap, (2) it prevents escape of odours and foul gases and thereby eliminates the nuisance from smell. Once the latrine is flushed, nightsoil is no longer visible. These merits have rendered the water seal type of latrine more acceptable to rural people than the bore hole or pit privy without water seal. Several designs of water seal latrines have been tested in the field, and two types have gained recognition for wide use. These are: (1) the P.R.A.I. type, evolved by the Planning, Research and Action Institute, Lucknow (Uttar Pradesh) and (2) the RCA type, designed by the Research–Action Action Projects in Environmental Sanitation of the Ministry of Health, Government of India. Of these two types, the RCA latrine has been accepted as a suitable design for wide adoption in different parts of the country (1). A brief description of the RCA latrine is given below:

The parts of a water-seal latrine, whether RCA type or PRAI type, are essentially the same (Fig. 6 & 9). The differences are in matters of minor engineering detail. The essential features of a RCA latrine and its installation are described below:

**RCA LATRINE**

(1) **LOCATION**

The safe distance between the latrine and a source of water supply will depend upon the porosity of the soil, level of ground water, its slope and direction of flow. In general, it may be stated, that latrines of any kind should not be located within 15 m (50 ft) from a source of water supply, and should be at a lower elevation to prevent the possibility of bacterial contamination of the water supply. Where possible, latrines should not be located in areas usually subject to flooding.

(2) **SQUATTING PLATE**

The squatting plate or slab (Fig. 6) is an important part of a latrine. It should be made of an impervious material so that it can be washed and kept clean and dry. If kept dry, it will not facilitate the survival of hookworm larvae. In recommending squatting plates, due consideration should be paid to the habits of Indian people who defecate in the squatting position and use water for anal washing. The slab of the RCA latrine has been designed to meet the above

Dug well latrine

**Fig. 6**

Squatting plate or slab

---

**Environment and Health**

A new hole is dug and similarly used. The nightsoil undergoes purification by anaerobic digestion and is eventually converted into a harmless mass. The amount of sludge that accumulates has been estimated to amount to 2.1 to 7.3 cubic feet per 1,000 users per day (2). The merits of a bore hole latrine are: (1) there is no need for the services of a sweeper for daily removal of nightsoil, (2) the pit is dark and unsuitable for fly breeding, (3) if located 15 m (50 ft) away from a source of water supply, there should be no danger of water pollution. In spite of these merits, bore hole latrines are not considered a very suitable type of latrine today. The reasons are: (a) the bore hole fills up rapidly because of its small capacity, (b) a special equipment, the auger, is required for its construction which may not be readily available, (c) in many places, the subsoil is high and the soil loose, with the result it may be difficult to dig a hole deeper than 3 m (10 ft.). The bore hole latrine is therefore, not very much in use today. It has been superseded by better innovations.

DUG WELL LATRINE

Dug well latrine or pit latrine (Fig. 4) was first introduced in Singhur, West Bengal in 1949–1950 (1). It is an improvement over the bore hole latrine. A circular pit about 75 cm (30 in.) in diameter and 3 to 3.5 m (10–12 ft.) deep is dug into the ground for the reception of the nightsoil. In sandy soil, the depth of the pit may be reduced to 1.5 to 2 m (6–7 ft.). The pit may be lined with pottery rings, and as many rings as necessary to prevent caving in of the soil may be used. A concrete squatting plate is placed on the top of the pit, and the latrine is enclosed with a superstructure. The advantages of this type of latrine are: (1) it is easy to construct and no special equipment such as an auger is needed to dig the pit, (2) the pit has a longer life than the bore hole because of greater cubic capacity. A pit 75 cm (30 in.) diameter and 3 to 3.5 m (10–12 ft.) deep will last for about 5 years for a family of 4 to 5 persons. When the pit is filled up, a new pit is constructed. The action of the dug well latrine is the same as in the bore hole latrine, i.e., anaerobic digestion.

WATER SEAL LATRINE

A further improvement in the designing of sanitary latrines for rural families is the hand-flushed “water seal” type of latrine (Fig. 5). Here, the squatting plate is fitted with a water seal. The water seal performs two important functions: (1) it prevents access by flies. That is, the nightsoil is sealed off from flies, by a small depth of water contained in a bent pipe called the trap, (2) it prevents escape of odours and foul gases and thereby eliminates the nuisance from smell. Once the latrine is flushed, nightsoil is no longer visible. These merits have rendered the water seal type of latrine more acceptable to rural people than the bore hole or pit privy without water seal. Several designs of water seal latrines have been tested in the field, and two types have gained recognition for wide use. These are: (1) the P.R.A.I. type, evolved by the Planning, Research and Action Institute, Lucknow (Uttar Pradesh) and (2) the RCA type, designed by the Research–Action Action Projects in Environmental Sanitation of the Ministry of Health, Government of India. Of these two types, the RCA latrine has been accepted as a suitable design for wide adoption in different parts of the country (1). A brief description of the RCA latrine is given below:

The parts of a water-seal latrine, whether RCA type or PRAI type, are essentially the same (Fig. 6 & 9). The differences are in matters of minor engineering detail. The essential features of a RCA latrine and its installation are described below:

**RCA LATRINE**

(1) LOCATION

The safe distance between the latrine and a source of water supply will depend upon the porosity of the soil, level of ground water, its slope and direction of flow. In general, it may be stated, that latrines of any kind should not be located within 15 m (50 ft) from a source of water supply, and should be at a lower elevation to prevent the possibility of bacterial contamination of the water supply. Where possible, latrines should not be located in areas usually subject to flooding.

(2) SQUATTING PLATE

The squatting plate or slab (Fig. 6) is an important part of a latrine. It should be made of an impervious material so that it can be washed and kept clean and dry. If kept dry, it will not facilitate the survival of hookworm larvae. In recommending squatting plates, due consideration should be paid to the habits of Indian people who defecate in the squatting position and use water for anal washing. The slab of the RCA latrine has been designed to meet the above
needs. It is made of cement concrete with minimum dimensions of 90 cm (3 ft) square and 5 cm (2 in.) thickness at the outer edge. There is a slope 1/2 inch towards the pan. This allows drainage into the latrine of the water used for ablation or cleansing purposes. A circular squatting plate of 90 cm (3 ft.) diameter and of 5 cm (2 in.) uniform thickness, has also been found satisfactory. For the convenience of the users, raised footrests are included in the squatting plate.

![FIG. 6 Squatting plate](image)

(3) PAN

The pan (Fig. 7) receives the nightsoil, urine and wash water. The length of the pan is 42.5 cm (17 in.). The width of the front portion of the pan has a minimum of 12.5 cm (5 in.) and the width at its widest portion is 20 cm (8 in.). There is a uniform slope from front to back of the pan. The pan is given a smooth finish.

![FIG. 7 Latrine pan](image)

(4) TRAP

The trap (Fig. 8) is a bent pipe, about 7.5 cm (3 in.) in diameter and is connected with the pan. It holds water and provides the necessary ‘water seal’. The water seal is the distance between the level of water in the trap and the lowest point in the concave upper surface of the trap. The depth of the water seal (AB) in the RCA latrine is 2 cm (3/4 in.) (Fig. 8). The water seal prevents the access by flies and suppresses the nuisance from smell.

![FIG. 8 Trap](image)

(5) CONNECTING PIPE

When the pit is dug, away from the squat plate, the trap is connected to the pit by a short length of connecting pipe 7.5 cm (3 in.) in diameter and at least 1 m (3 ft.) in length with a bend at the end (Fig. 9). A latrine of this type is called the Indirect type because the pit is sited away from the squatting plate. In the direct type there is no need for a connecting pipe (Fig. 5). The direct type is best suited for areas where the ground is hard and does not easily cave in. The direct type is cheaper and easier to construct and occupies less space (1). An advantage with the indirect type is that when the pit fills up, a second pit can be put into operation by merely changing the direction of the connecting pipe. Therefore, the indirect type is usually preferred.

(6) DUG WELL

The dug well or pit is usually 75 cm (30 in.) in diameter, and 3 to 3.5 m (10–12 ft.) deep and is covered. In loose soil and where the water table is high a lining of earthenware rings or bamboo matting can be used to prevent caving in of the pit (1). When the pit fills up, a second pit is dug nearby and the direction of the connecting pipe is changed into the second pit. When the second pit fills up, the first one may be emptied and reused.

(7) SUPERSTRUCTURE

The desired type of superstructure may be provided for privacy and shelter. An attractive superstructure with a neat finish is desirable as this will be generally well maintained.

![FIG. 9 RCA Latrine (Indirect type)](image)
(8) MAINTENANCE

The life of a latrine will depend upon several factors such as care in usage and maintenance. The latrine should be used only for the purpose intended and not for disposal of refuse or other debris. The squatting plate should be washed frequently and kept clean and dry. People should learn to flush the pan after use with adequate quantity of water. One to two litres of water are sufficient to flush the RCA latrine. Thus, proper maintenance involves health education of the people which is very necessary for the success of any latrine programme.

SEPTIC TANK

The septic tank (Fig. 10) is water-tight masonry tank into which household sewage is admitted for treatment. It is a satisfactory means of disposing excreta and liquid wastes from individual dwellings, small groups of houses and institutions which have adequate water supplies but do not have access to a public sewerage system.

![Diagram of a septic tank](image)

**FIG. 10**

Septic tank

**DESIGN FEATURES**

There are various designs in septic tanks. Some are double chambered and some single chambered. A single chambered septic tank has been found satisfactory for small installations. Tanks with more than two compartments are expensive and have shown little advantage over the two or multiple chambered septic tank (5).

The main design features of a septic tank are as follows:

1. **Capacity**: The capacity of a septic tank will depend upon the number of users. A capacity of 20–30 gallons or 21/2–5 c.f.t. per person is recommended for household septic tanks. The minimum capacity of a septic tank should be at least 500 gallons. Septic tanks are not recommended for large communities.

2. **Length**: The length is usually twice the breadth.

3. **Depth**: The depth of a septic tank is from 1.5 to 2 m (5–7 ft.).

4. **Liquid depth**: The recommended liquid depth is only 1.2 m (4 ft.).

5. **Air space**: There should be a minimum air space of 30 cm (12 in.) between the level of liquid in the tank and the underside of the cover.

6. **Bottom**: In some septic tanks, the bottom is sloping towards the inlet end. This facilitates retention of solids.

7. **Inlet and outlet**: There is an inlet and outlet pipe, which are submerged.

(8) **Cover**: The septic tank is covered by a concrete slab of suitable thickness and provided with a manhole.

(9) **Retention Period**: Septic tanks are designed in this country to allow a retention period of 24 hours. Too long a retention period will result in undue seepage of the effluent whereas too short a period gives insufficient treatment.

**WORKING OF A SEPTIC TANK**

The solids settle down in the tank, to form "sludge", while the lighter solids including grease and fat rise to the surface to form "scum". The solids are attacked by the anaerobic bacteria and fungi and are broken down into simpler chemical compounds. This is the first stage of purification, called anaerobic digestion. The sludge is much reduced in volume as a result of anaerobic digestion, and is rendered stable and ineffective. A portion of the solids is transferred into liquids and gases (principally methane) which rises to the surface in the form of bubbles.

The liquid which passes out of the outlet pipe from time to time is called the "effluent". It contains numerous bacteria, cysts, helminthic ova and organic matter in solution or fine suspension. The effluent is allowed to percolate into the sub-soil. It is dispersed by means of perforated or open-jointed pipes laid in trenches 90 cm (3 ft.) deep and the trenches are then covered with soil. The effluent percolates into the surrounding soil. There are millions of aerobic bacteria in the upper layers of the soil, which attack the organic matter present in the effluent. As a result, the organic matter is oxidized into stable end-products, i.e., nitrates, carbon dioxide and water. This stage of purification is called aerobic oxidation.

To sum up, the two stages are involved in the purification of sewage. The first stage, anaerobic digestion takes place in the septic tank proper, and the second stage, aerobic oxidation takes place outside the septic tank, in the sub-soil. Together, these two stages complete the purification of sewage.

**OPERATION AND MAINTENANCE**

(1) The use of soap water and disinfectants such as phenol should be avoided as they are injurious to the bacterial flora in the septic tank. (2) Undue accumulation of sludge reduces the capacity of the septic tank and interferes with proper working. Therefore, the contents of the septic tank should be bailed out at least once a year. This operation is called "desludging". The bailed out sludge is disposed of by trenching. (3) Newly built septic tanks are first filled with water up to the outlet level and then seeded with ripe sludge drawn from another septic tank, to provide the right type of bacteria to carry out the decomposition process.

**AQUA PRIVY**

The Aqua privy (Fig. 11) functions like a septic tank and has been used in different regions in the country (1). The privy consists of a water-tight chamber filled with water. A short length of a drop pipe from the latrine floor dips into the water. The shape of the tank may be circular or rectangular. The size of the tank depends upon the number of users. A capacity of one cubic metre (35 c.u.f.t.) is recommended for a small family, allowing 6 years or more for cleansing purposes. Aqua privies are designed for public use also.
Night soil undergoes purification by anaerobic digestion. Since there is evolution of gases into the atmosphere, the vent should be open above the roof of dwellings. The effluent is tar from innocuous. It contains finely divided fecal matter in suspension and may carry parasitic and infective agents. It should be treated in the same manner as the effluent from a septic tank by sub-soil irrigation or absorption. The digested sludge which accumulates in the tank should be removed at intervals.

SULABH SHAUCHALAYA

The "Sulabh Shauchalaya" model, the invention of a Patna-based firm, is a low cost pour-flush, water-seal type of latrine, which is now being used in many parts of India. Basically it is an improved version of the standard handflush latrine (e.g., RCA type). It consists of a specially designed pan and a water-seal trap. It is connected to a pit 3 feet square and as deep. Excreta undergoes bacterial decomposition and is converted to manure (compost). The method requires very little water.

Sulabh International, the investors, not only build but also maintain the system of Sulabh Community Latrines. Their usual structure is a lavatory block of several dozen seats, with a bathing block adjoining. The system is to charge Rs. 5 per user. Delhi has opted for this system in all its alumns. This system has drawn praise from ecologists and planners.

CHEMICAL CLOSET

It has very limited use under Indian conditions. The closet consists of a metal tank containing a disinfectant fluid. The active ingredients of the fluid are formaldehyde and quaternary ammonium compounds. In addition, a harmless water dye and a deodorizing substance are usually incorporated. A seat with a cover is placed directly over the tank. Nothing except the toilet paper should be thrown into the chemical closet.

SHALLOW TRENCH LATRINE

This is simply a trench dug with ordinary tools. The trench is 30 cm (1 ft) wide and 90–150 cm (3–5 ft) deep. Its length depends on the number of users: 3–3.5 m (10–12 ft) are necessary for 100 people. Separate trenches should be provided for men and women. The earth from the trench should be piled up at the side. People should be instructed to cover faces with earth each time they use the latrine. However, these instructions may not be carried out, and it will be necessary to post sweepers in attendance to do this work. Ablution water should be provided. The shallow trench is a rudimentary arrangement for a short period (upto one week). When the trench is filled to 30 cm (12 in.) below ground level, it must be covered with earth, heaped above ground level and compacted; if necessary, a new trench must be dug (9).

DEEP TRENCH LATRINE

This type of latrine is intended for camps of longer duration, from a few weeks to a few months. The trench is 1.8 to 2.5 m (6–8 ft.) deep and 75–90 cm (30–35 in.) wide. Depending upon the local customs, a seat or a squatting plate is provided. A superstructure is built for privacy and protection. Other requirements are the same as for shallow trench latrine (8).

WATER CARRIAGE SYSTEM

The water carriage system or sewerage system implies collecting and transporting of human excreta and waste water from residential, commercial and industrial areas, by a net-work of underground pipes, called sewers to the place of ultimate disposal. It is the method of choice for collecting and transporting sewage from cities and towns where population density is high. There are two types in water carriage system - the combined sewer system and the separate sewer system. In the combined system, the sewers carry both the sewage and surface water. In the separate system, surface water is not admitted into sewers. The separate system is considered the system of choice today. Although the first sewers were laid in 1867 in Calculta, the Mudalilar Committee (1962) reported that not more than 15 per cent of the urban population in India had the amenity of a sewerage system. The problem is one of economics - a heavy outlay of capital is needed to install a water-carryage system. Since water is needed for flushing the toilets and for conveying the human wastes, there can be no sewerage system without a piped water supply.

A water carriage system consists of the following elements:
1. Household sanitary fittings (plumbing system of buildings)
2. House sewers
3. Street sewers or trunk sewers
4. Sewer appurtenances: manholes, traps, etc.

1. Household sanitary fittings

Where sewers exist, every house is expected to be connected to the nearest sewer. The usual household sanitary fittings are: (i) water closet, (ii) urinal and (iii) wash basins.

WATER CLOSETS may be broadly divided into two types: Indian squatting type (Fig. 6) and the Western commode type. An ideal water closet bowl (western type) is shown in Fig. 12. It is recommended that for efficient performance: (a) the water seal area should not be more than 7.5 cm (2). (b) there should not be any sharp corners in the trap design. (c) the volume of water in trap should be as little as possible, preferably not exceeding 1.75 litres to maintain a minimum of 50 mm deep water seal, and (d) the interior of the bowl should be vertical at least 50 to 75 mm just above the surface of water seal (9). The water closets are provided with a 'flushing rim'. Human excreta is directly

FIG. 11 Aquas privy
2. House drain
The house drain is usually 10 cm (4 in.) in diameter and is laid in the courtyard about 15 cm (6 in.) below the ground level on a bed of cement concrete with sufficient gradient towards the main drain. The house drain empties the sewage into the main sewer or public drain.

3. Potlic sewer
The trunk sewers are not less than 22.5 cm (9 in.) in diameter, larger ones may be 2 to 3 m (8–10 ft.) in diameter. They are laid on a bed of cement concrete, about 3 m (10 ft.) below the ground level, with sufficient gradient to ensure what is known as "self-cleansing" velocity; this varies from 2 to 3 feet per second. The trunk sewers collect sewage from several houses and transport to the main outfall or place of final disposal.

4. Sewer apparatus
These are (a) manholes and (b) traps which are installed in the sewerage system. MANHOLES are openings built into the sewerage system. They are placed (a) wherever there is a change in the direction of sewers, (b) at the meeting point of two or more sewers, and (c) at distances of 100 metres in long straight runs. These openings permit a man to enter the sewer for inspection, repairs and cleaning. Workers entering the manholes are liable to gas poisoning and asphyxiation. Due precautions should be taken to ensure their safety. TRAPS are of various kinds, these are devices designed to prevent foul gases entering the houses and to remove sand, grit and grease from sewage. traps are placed in three situations: (a) under the basin of water closets, (b) where the house drain joins the public drain (interceptor trap), and (c) where surface waste water enters the drains.

The installation of a sewerage system is a huge engineering problem. It involves considerable planning, designing, construction, operation, maintenance and administration – each calling for specialized skills. Sewer systems are designed, like water supplies, for service for one generation (50 years).

Sewage
What is sewage?
Sewage is waste water from a community, containing solid and liquid excreta, derived from houses, street and yard washings, factories and industries. It resembles dirty water with an unpleasant smell. The term "sullage" is applied to waste water which does not contain human excreta, e.g., waste water from kitchens and bathrooms. The amount of sewage that flows in the sewers depends upon: (a) Habits of the people: If people use more water, there will be more sewage. (b) Time of day: Sewage does not flow uniformly throughout the day. It is subject to variations depending upon the time of day and during different seasons. In the morning, when people tend to use more water there is greater quantity and flow; in mid-day the flow is less, and again there is a slight increase in the evening. The average amount of sewage which flows through the sewerage system in 24 hours is called the "dry weather flow."

Health aspects
Unless prompt measures are taken to provide proper means of sewage disposal, the following environmental problems may be created:

a. creation of nuisance, unpleasantness and unpleasant odours
b. breeding of flies and mosquitoes
c. pollution of soil and water supplies
d. contamination of food, and
e. increase in the incidence of disease, especially enteric and helminthic diseases.

Composition of sewage
Sewage contains 99.9 per cent of water. The solids which comprise barely 0.1 per cent are partly organic and partly inorganic; they are partly in suspension and partly in solution. The offensive nature of the sewage is mainly due to the organic matter which it contains. The organic matter decomposes according to the laws of nature during which process it gives off offensive odours. In addition, sewage is charged with numerous living organisms derived from faeces, some of which may be agents to disease. It is estimated that one gram of faeces may contain about 1,000 million of E. coli, 10 to 100 million of faecal streptococci, and 1 to 10 million spores of C. perfringens besides several others. The average adult person excretes daily some 100 gram of faeces.

Aim of sewage purification
Raw sewage or inadequately treated sewage should not be discharged into rivers, seas or other sources of water supply. This is because, the oxygen in the water supply is used up by the numerous aerobic bacteria found in the sewage. Depletion of oxygen may lead to the death of the plant and animal life in water. Furthermore, the water may yield as offensive smell because of the release of hydrogen sulphide.

The aim of sewage treatment is to "stabilize" the organic matter so that it can be disposed off safely; and, to convert the sewage water into an effluent of an acceptable standard of purity which can be disposed off in to land, rivers or sea. A standard test which is an indicator of the organic content of the sewage is biochemical oxygen demand (BOD).
The "strength" of the sewage is expressed in terms of:
(a) BIOCHEMICAL OXYGEN DEMAND (BOD): It is the most important test done on sewage. It is defined as the amount of oxygen absorbed by a sample of sewage during a specified period, generally 5 days, at a specified temperature, generally 20°C. For the aerobic destruction or use of organic matter by living organisms (10). BOD values range from about 1 mg per litre for natural waters to about 300 mg per litre for untreated domestic sewage. If the BOD is 300 mg/L and above, sewage is said to be "strong"; if it is 100 mg/L, it is said to be "weak".
(b) CHEMICAL OXYGEN DEMAND (COD): The COD test measures the oxygen equivalent of that portion of the organic matter in a sample which is susceptible to oxidation by a strong chemical oxidiser. If wastes contain toxic substances, this test may be the only practical method for determining the organic load. (c) SUSPENDED SOLIDS: The suspended solids are yet another indicator of the "strength" of sewage. The amount of suspended solids in domestic sewage may vary from 100 to 500 p.p.m. (mg/L). If the amount of suspended solids is 100 mg/L, the sewage is said to be weak; if the amount is 500 mg/L, the sewage is said to be strong.

Decomposition of organic matter

The decomposition of organic matter in sewage takes place by two processes: aerobic and anaerobic processes.

1. Aerobic process: It is the most efficient method of reducing the organic matter in sewage. The process requires a continuous supply of free dissolved oxygen. The organic matter is broken down into simple compounds namely CO₂, water, ammonia, nitrates and sulphates by the action of bacterial organisms including fungi and protozoa.

2. Anaerobic process: Where the sewage is highly concentrated and contains plenty of solids, the anaerobic process is highly effective. The end-products of decomposition are methane, ammonia, CO₂ and H₂. In anaerobic decomposition, the reactions are slower and the mechanism of decomposition extremely complex.

MODERN SEWAGE TREATMENT

Modern sewage treatment plants are based on biological principles of sewage purification, where the purification is brought about by the action of anaerobic and aerobic bacteria. Fig. 13 shows the flow diagram of a modern sewage treatment plant. The treatment of sewage may be divided into two stages, primary treatement and secondary treatment. In primary treatment, the solids are separated from the sewage partly by screening and partly by sedimentation and subjected to anaerobic digestion which is the first stage in purification; in secondary treatment, the effluent is subjected to aerobic oxidation, which is the second stage in purification.

a. PRIMARY TREATMENT

1. Screening

Sewage arriving at a disposal work is first passed through a metal screen which intercepts large floating objects such as pieces of wood, rags, masses of garbage and dead animals. Their removal is necessary to prevent clogging of the treatment plant. The screen consists of vertical or inclined steel bars usually set 5 cm (2 in) apart. In some plants, the screens are of the fixed type while in others, the screens are of the moving type. The screenings are removed from time to time either manually or mechanically, and disposed off by trenching or burial.

2. Grit chamber

Sewage is then passed through a long narrow chamber called the grit chamber or degrit chamber. This chamber is approximately 10 to 20 metres in length; it is so designed as to maintain a constant velocity of about 1 foot per second, with a detention period of 30 seconds to 1 minute (10). The function of the grit chamber is to allow the settlement of heavier solids such as sand and gravel, while permitting the organic matter to pass through. The grit which collects at the bottom of the chamber is removed periodically or continuously, and disposed off by plain dumping or trenching.

Flow diagram of a modern sewage treatment plant
3. Primary sedimentation

Sewage is now admitted into a huge tank called the primary sedimentation tank. It is a very large tank, holding from \( \frac{1}{4} \) to \( \frac{1}{3} \) of the daily dry weather flow. There are various activities in primary sedimentation tank. By far the commonest is the rectangular tank. Sewage is made to flow very slowly across the tank at a velocity of 1–2 feet per minute. The sewage spends about 6–8 hours in the tank. During this long period of relatively still conditions in the tank, a very considerable amount of purification takes place mainly through sedimentation of suspended matter. Nearly 50–70 per cent of the solids settle down under the influence of gravity. A reduction of between 30 to 40 per cent in the number of coliform organisms is obtained (11). The organic matter which settles down is called sludge and is removed by mechanically operated devices, without disturbing the operation in the tank. While this is going on, a small amount of biological action also takes place in which the microorganisms present in the sewage attack complex organic solids and break them down into simpler soluble substances and ammonia. A certain amount of fat and grease rise to the surface to form scum which is removed from time to time and disposed of. When the sewage contains organic trade wastes, it is treated with chemicals such as lime, aluminium sulphate and ferrous sulphate. Addition of one of these chemicals precipitates the animal protein material quickly.

b. SECONDARY TREATMENT

The effluent from the primary sedimentation tank still contains a proportion of organic matter in solution or colloidal state, and numerous living organisms. It has a high demand for oxygen and can cause pollution of soil or water. It is subjected to further treatment, aerobic oxidation, by one of the following methods:

(a) Trickling filter method
(b) Activated sludge process.

(a) TRICKLING FILTER METHOD

The trickling filter or percolating filter is a bed of crushed stones or cinder, 1 to 2 m (4–8 ft) deep and 2 to 3 m (6–100 ft) in diameter, depending upon the size of the population. The effluent from the primary sedimentation tank is sprinkled uniformly on the surface of the bed by a revolving device. The device consists of hollow pipes each of which has a row of holes. The pipes keep rotating, sprinkling the effluent in a thin film on the surface of the filter. Over the surface and down through the filter, a very complex biological growth consisting of algae, fungi, protozoa and bacteria of many kinds occurs. This is known as the "zoogleal layer." As the effluent percolates through the filter bed, it gets oxidized by the bacterial flora in the zoogleal layer. The action of the filter is thus purely a biological one, and not one of filtration as the name suggests. The trickling filters are very efficient in purifying sewage. They do not need rest pauses, because wind blows freely through the beds and the oxygen needed by the zoogleal flora. The biological growth or zoogleal layer lives, grows and dies. The dead matter sloughs off, breaks away and is washed down the filter. It is a light green, flocculent material and is called "humus." The oxidized sewage is now led into the secondary sedimentation tanks or humus tanks.

(b) ACTIVATED SLUDGE PROCESS

Activated sludge process (Fig. 14) is the modern method of purifying sewage, in place of the trickling filter. The "heart" of the activated sludge process is the aeration tank. The effluent from the primary sedimentation tank is mixed with sludge drawn from the final settling tank (also known as activated sludge or return sludge; this sludge is a rich culture of aerobic bacteria). The proportion of activated sludge to the incoming effluent is of the order of 20 to 30 per cent. The mixture is subjected to aeration in the aeration chamber for about 6 to 8 hours (10). The aeration is accomplished either by mechanical agitation or by forcing compressed air continuously from the bottom of the aeration tank. This latter method, also known as "diffuse aeration" is considered a better method of aeration. During the process of aeration, the organic matter of the sewage gets oxidized into carbon dioxide, carbonates and water with the help of the aerobic bacteria in the activated sludge. The end-products are definitely destroyed, and the colloids greatly reduced. Activated sludge plants occupy less space, require skilled operations. One acre of activated sludge plant does the work of 10 acres of percolating filter. Activated sludge process is, therefore, best suited for larger cities and the percolating filter for smaller towns because they are cheaper to install and easier to operate.

Secondary sedimentation

The oxidized sewage from the trickling filter or aeration chamber is led into the secondary sedimentation tank where it is detained for 2–3 hours. The sludge that collects in the secondary sedimentation tank is called "activated sludge" or activated sludge, because it is fully aerated. It differs from the sludge in the primary sedimentation tank in that it is practically indigestive and is rich in bacteria, nitrogen and phosphates. It is a valuable manure, if dehydrated. Part of the activated sludge is pumped back into the "aeration tanks" in the activated sludge process and the rest pumped into the sludge digestion tanks for treatment and disposal.

---
Sludge digestion
One of the greatest problems associated with sewage treatment is the treatment and disposal of the resulting sludge. Each million gallons of sewage produces 15-20 tons of sludge. The sludge is thick, black mass containing 95 per cent of water, and it has a revolving odour. There are a number of methods of sludge disposal.

Modern sewage treatment plants employ digestion of sludge as the method of treatment. If sludge is incubated under favourable conditions of temperature and pH it undergoes anaerobic auto-digestion in which complex solids are broken down into water, carbon dioxide, methane and ammonia.

The volume of sludge is also considerably reduced. It takes 3-4 weeks or longer for complete sludge digestion. The residue is inoffensive, sticky and tarry mud which will dry readily and form an excellent manure. Sludge digestion is carried out in special tanks known as "sludge digestion tanks". Methane gas, which is a by-product of sludge digestion, can be used for heating and lighting purposes.

(b) Sea disposal: Sea coast towns and cities can dispose of sludge by sludging it into the sea. (c) Land: Sludge can be disposed of by composting with town refuse.

Disposal of effluent
(a) Disposal by dilution: Disposal into water courses such as rivers and streams is called "disposal by dilution". The effluent is diluted in the body of water and the impurities are oxidized by the dissolved oxygen in the water. The diluting capacity of the river or the receiving body of water and its dissolved oxygen contents are important considerations before discharging the effluent into a river or any body of water. Since people use river water for drinking purpose, the effluent from the sewage plant should not contain any microorganisms or other organic natures that can affect the environment. These standards have been the backbone of subsequent work on the purity of sewage effluent. During the past few years, industry has developed hundreds of new chemicals which are released into the sewage system. Some of these chemicals are not removed by biological treatment. Consequently, the effluent may contain substances toxic to man, or substances that can kill fish, damage agriculture or interfere with the normal functioning of a stream. In many places in the UK, effluent standards have been relaxed from the original Royal Commission values of 30 mg per litre of suspended solids and 20 mg per litre of B.O.D. to 10 mg per litre of each (11). The World Health Organisation is seized with this problem, and is fostering research in "tertiary" methods of treatment or "polishing" the effluent further. (b) Disposal on land: If suitable land is available the effluent can be used for irrigation purposes (e.g., the Othiba Sewage Treatment Plant in Delhi).

OTHER METHODS OF SEWAGE DISPOSAL
(a) Sea outfall
(b) River outfall
(c) Land treatment
(d) Oxidation ponds
(e) Oxidation ditches.
extent from the atmosphere but mostly from the algae which liberates oxygen under the influence of sunlight. Consequently, sunlight is an important factor in the proper functioning of oxidation ponds. Cloudy weather definitely lowers the efficiency of the process.

The oxidation ponds are predominantly aerobic during sunshine hours as well as some hours of the night. In the remaining hours of the night, the bottom layers are generally anaerobic. Thus the sewage purification in oxidation ponds is brought about by a combination of aerobic and anaerobic types of bacteria. The effluent may be used for growing vegetable crops (land irrigation) or may be discharged into a river or other water courses after appropriate treatment. Mosquito nuisance is avoided by keeping weed growth in the neighborhood of oxidation ponds to a minimum and the water line free from marginal vegetation. There is no odour nuisance associated with these ponds when they are properly maintained. Oxidation ponds have become an established method of purifying sewage for small communities.

(e) Oxidation ditches

Other methods recommended are (1) oxidation ditches and (2) aerated lagoons. These methods make use of mechanical rotors for extended aeration. For treatment of the wastes of a population between 5,000 to 20,000 an oxidation ditch requires an area of one acre as compared to 22 acres for an oxidation pond and 2.5 acres for an aerated lagoon. These are low-cost treatment methods for the purification of sewage.

SOCIAL ASPECTS OF EXCRETA DISPOSAL IN INDIA

India is a land of villages and about 70 per cent of its population lives in villages. The problem of sanitation therefore is one of "Rural sanitation". Surveys have shown that substantial per cent of the population "go to the open fields" for defecation. This habit of indiscriminate fouling of the surroundings with human excrement is generations-old, and rooted firmly in the cultural behaviour of the village people.

In urban areas, the latrine is considered a necessary part of a house. In rural areas, by and large, people have not accepted latrines with any enthusiasm, and even when installed only a few used them regularly. The problem in rural sanitation is how to overcome the resistance of the village people, and induce them to use sanitary latrines. Research studies have indicated that there is only one way to solve the problem, i.e., through health education. Social scientists have listed the reasons why villagers do not accept latrines. Some of the reasons found in the surveys are: (1) latrines are associated with bad smell (2) they are breeding places of flies (3) they are something foul and dirty so that one should not have them close to houses (4) latrines are costly and beyond their means to install, and (5) they do not know how faecal-borne diseases are spread. Secondly, using a latrine goes against a daily habit pattern of going to the fields. The use of latrines involves a drastic change in the day to day behaviour of a large number of people.

The solution to the problem lies in teaching the people first the reasons why latrines are important. The teaching should be undertaken by all known methods of health education – direct discussion, group discussion, latrine demonstration, and use of visual aids and above all service facilities. The ultimate goal of health education will be to motivate the rural people towards acceptance and use of sanitary latrines.

Surface water drainage in urban areas

Many low income communities in developing countries consider stormwater drainage to be their most urgent need as far as urban infrastructure is concerned. It is the coastal regions of the world that have the highest average rainfall, but the flat estuarine terrain and often impermeable alluvial soil make drainage difficult. Even in the arid areas where average rainfall is low, tropical rainfall – when it comes – is more intense than in temperate climates, and the lack of vegetation and of adequate drainage means that torrents of water can form in minutes, causing damage to homes and
property, which will take years to repair. The lack of drainage is especially serious where the ground is either steeply sloping, as in Hongkong or very flat as in Kolkata, Bangkok and Manila.

Deaths due to drowning in floods or burial beneath landslides or collapsing homes are perhaps the most dramatic signs of the suffering that drainage can help to alleviate. Less noticeable to an outsider, but of greater impact on the residents living in a poor community, is the steady toll of disease, disability and death by standing water.

First in public health importance are the many "faecal-oral" infections acquired by consumption of contaminated food and water. Children are particularly exposed to infection when playing or bathing in surface water. Surface water becomes contaminated with pathogens from blocked sewers and overflowing septic tanks. This contaminated surface water can infect people in many ways.

Another important group of diseases related to poor drainage and unsanitary conditions are the zoonoses, and malaria is the best example. Transmission can be particularly intense in urban areas where there are relatively few animals to divert the vector species of mosquitoes from human blood meals. Drainage construction is an effective mosquito control measure. It is cheaper than application of insecticides and does not have to be repeated regularly. Unlike insecticides, it can have no detrimental effect on the environment; on the contrary, it constitutes an environmental improvement.

Urban poor may often build on land with drainage problems, but good urban planning can help to avoid making these problems worse. One of the simplest planning measures is to set out regular plots before house building starts in an area, leaving space for well-aligned roads. Adequate road width and alignment will make it much easier to build drains when they are needed later.

Distinctive characters

The distinctive characters of the above arthropods are as given in Table 2.

Arthropod-borne diseases

Arthropod-borne diseases constitute a major health problem in India. Malaria continues to be an important vector-borne disease with an annual morbidity of 4 to 5 million cases. Filariasis is another important arthropod-borne disease with an estimated 236 million people living in filariasis- endemic areas. About 5 million people are estimated to be living in areas where guinea-worm disease is endemic. Scabies is a widespread disease, especially in rural areas. Dengue, haemorrhagic fever, Japanese encephalitis and NFD are also among the important arthropod-borne virus diseases in India. The prevalence rates for trachoma which is a major cause of blindness in India vary from 0.5 percent in West Bengal to 79 per cent in Punjab and Haryana. Thus,
arthropods are responsible for much ill-health and deaths (Table 3).

**Principles of arthropod control**

The general principles of arthropod control are:

1. Environmental control
2. Chemical control
3. Biological control
4. Genetic control

(1) Environmental control: This offers the best approach to the control of arthropods, because the results are likely to be permanent. Examples of environmental manipulation are: elimination of breeding places (source reduction); filling and drainage operation; carefully planned water management; provision of piped water supply; proper disposal of refuse and other wastes; cleanliness in and around houses, etc. Intensive health education of the public as well as political support are essential prerequisites. (2) Chemical control: A wide range of insecticides belonging to the organochlorines, organo-phosphorus and carbamate groups of compounds (Fig. 17, page 784) are available for vector control. It must be mentioned that vector control by insecticides alone is no longer fully effective because resistance has appeared in over 100 species of arthropods of public health importance. This coupled with the danger of environmental contamination has led to restricted use of many insecticides in some countries. To avoid undue environmental pollution, it is now considered essential to replace gradually the highly persistent compounds such as DDT with compounds which are readily "biodegradable" and less toxic to man and animals such as metoxychlor, alate and dursban (1). As there is no alternate control method which is as efficient and economical as the insecticides, it is postulated that most of the developing countries will have to depend, for sometime to come, on the organochlorine compounds for the control of vectors. (3) Biological control: To minimize environmental pollution with toxic chemicals, great emphasis is now being placed on biological control. The use of larvicidal fish especially Gambusia is well known in mosquito control. Fungi of the genus Coelomomyces are also known to be pathogenic to mosquitoes. A variety of other biological agents (e.g., bacteria, fungi, nematodes, protozoa and viruses) are under study for the control of insects. But the fear exists that the introduction of biological agents for the control of arthropods may pose a direct hazard to the health of man himself (2). (4) Genetic control: Much progress has taken place in recent years in the theoretical and applied means an "arthropod or other invertebrate which transmits infection by inoculation into or through the skin or mucous membrane by biting, or by deposit of infective materials on the skin or on food or other objects". The period of time necessary for the development of the disease agent in the arthropod host is called extrinsic incubation period. For example, the extrinsic incubation period in malaria and filariasis are from 10 to 14 days or longer depending upon the environmental temperature. The host in which the sexual cycle of the agent occurs is called the definitive host, e.g., mosquito is the definitive host in malaria. The bite in which the asexual cycle of the agent occurs is called the intermediate host e.g., mosquito in filaria and cyclops in guinea-worm disease. By infestation is meant the lodgment, development and reproduction of arthropods on the surface of the body or in the clothing e.g., lance infestation.

**Transmission of arthropod-borne diseases**

Three types of transmission cycles are involved in the spread of arthropod-borne disease: (1) DIRECT CONTACT: In this method of spread, the arthropod are directly transferred from man to man through close contact, e.g., scabies and pediculosis. (2) MECHANICAL TRANSMISSION: The disease agent is transmitted mechanically by the arthropod. The transmission of diarrhoea, dysentery, typhoid, food poisoning and trachoma by the housefly - are examples of mechanical transmission of the disease agent by the vector. (3) BIOLOGICAL TRANSMISSION: When the disease agent multiplies or undergoes some developmental change with or without multiplication in the arthropod host, it is called biological transmission. This may be of three types: (a) Propagative: When the disease agent undergoes no cyclical change, but multiplies in the body of the vector, transmission is said to be propagative, e.g., plague bacilli in rat fleas (b) Cyclopropagative: The disease agent undergoes cyclical change, and multiplies in the body of the arthropod, e.g., malaria parasite is anopheline mosquito (c) Cyclo-developmental: When the disease agent undergoes cyclical change but does not multiply in the body of the arthropod, e.g., filarial parasite in culex mosquito and guineaworm embryo in cyclops.

In communicable disease terminology, the word vector
aspects of genetic control of arthropods. The WRI/ICMR
Research Unit at New Delhi has contributed massively to the
techniques of genetic control of mosquitoes (3). Techniques
such as sterile male technique, cytoplasmic incompatibility
and chromosomal translocations have been found to be
effective in small field trials. In conclusion, it may be stated
that these methods are nowhere near the stage where they
 can be used large-scale in an effective way. (5) **Neuter
methods**: New and innovative methods are being sought
for pest control. These are (a) insect growth
regulators (b) chemosterilants, and (c) sex attractants or
pheromones (4).

**Integrated approach**
Since no single method of control is likely to provide a
solution in all situations, the present trend is to adopt an
"integrated approach" for vector control combining two or
more methods with a view to obtain maximum results with
the minimum effort and to avoid the excessive use of any
one method (5).

**MOSQUITO**

**General description**
Mosquitoes constitute the most important single family of
insects from the standpoint of human health. They are found
all over the world. The four important groups of mosquitoes
in India which are related to disease transmission are the
Anopheles, Culex, Aedes and Mansonia.

The body of a mosquito consists of three parts: head,
thorax and abdomen, (a) **HEAD**: The head is semi-globular
in outline, and bears the following structures:— (i) a pair of
large compound eyes (ii) a long needle-like structure, called
the proboscis with which the mosquito bites (iii) a pair of
pilus, each a four-jointed structure, situated on either side
of the proboscis and (iv) a pair of antennae or feelers. The
antennae are bushy in the male, and not quite so in the
female. They provide an easy means of distinguishing the
male from the female (b) **THORAX**: The thorax is large and
rounded in appearance and bears:— (i) a pair of wings
dorsally (ii) three pairs of legs ventrally. The wings of the
mosquito are characterised by a fringe of scales on the
posterior border and the first, third and sixth veins on the
wings are not branched. When the mosquito is at rest, the
wings are folded. The buzzing noise which the mosquitoes
produce is due to the beating of their wings, and not to
"singing". (c) **ABDOMEN**: The abdomen is long and narrow
and is composed of 10 segments, the last two of which are
modified to form the external genitalia.

**Life history**
There are four stages in the life history of mosquitoes (Fig. 1): egg, larva, pupa and adult. Metamorphosis is
complete.

(1) **EGG**: Eggs are laid on the surface of water, 100–250
at a time. The Anopheles lays her eggs singly; the eggs are
boat-shaped and possess lateral floats. The Culex lays her
eggs in small clusters or rafts; the eggs do not possess lateral
floats. The Aedes lays her eggs singly; the eggs are cigar-
shaped and do not possess lateral floats. The Mansonia lays
her eggs in star-shaped clusters attached to the under-
surface of the leaves of certain aquatic plants, notably the
pistia plant. Under favourable conditions, the egg stage of
mosquitoes lasts for 1–2 days. The period that elapses from
the moment a blood meal is taken until the eggs are laid is
called the "gonotrophic cycle", it is about 48 hours in hot
and humid tropical areas.

(2) **LARVA**: The larva is a free swimming creature with
an elongated body divisible into head, thorax and abdomen.
It feeds on algae, bacteria and vegetable matter and passes
through four stages of growth called "instars" with moultling
between each stage. The larva of the Anopheles floats
horizontally, in the water, and has no siphon tube at the tip
of its abdomen. The Culicite (e.g., Culex, Aedes and
Mansonia) larvae, in contrast, are suspended in water with
their heads downwards; they all possess a siphon tube,
which is situated on the 8th abdominal segment. The larvae
of the Mansonia are peculiar in the respect that they are
attached to the roots of certain aquatic plants by their
siphon tubes; they obtain the air from the plant roots.
The larval stage occupies 5–7 days.

(3) **PUPA**: The pupa is comma-shaped in appearance,
with a large rounded cephalothorax and a narrow abdomen.
Two small respiratory tubes or trumpets project from the
upper surface of the thorax. The pupa represents the resting
stage in the life history of the mosquito; it does not feed but
prefers to stay quiet at the water surface. But when disturbed
it swims rapidly downwards into the water. The pupal stage
lasts for 1–2 days.

(4) **ADULT**: When the development is complete, the

---

**FIG. 1**
Life cycle of a mosquito
pupal skin splits along the back and the adult mosquito or imago emerges. It rests for a while on the pupal skin to allow its wings to expand and harden and then flies away. Under favourable conditions of temperature and food supply the life cycle from the egg to adult is complete in 7–10 days. Normally the adult mosquito lives for about 2 weeks. The males are generally short-lived.

**Differentiation between anophelines and culicines**

There are two main tribes of mosquitoes – Tribe Anophellini and Tribe Culicini. The tribe Anophellini contains only one genus, Anopheles. The tribe Culicina is represented in India by 15 genera of which the important ones are Culex, Aedes and Mansonia. The main points of difference between the two tribes, Anophellini and Culicina are as given in Table 4 (See Fig. 2).

(1) *Anopheles*

Some 45 species of *Anopheles* mosquitoes have been found in India but only a few of them have been incriminated as vectors or carriers of malaria. They are (1) *A. culicifacies* (2) *A. fluviatilis* (3) *A. minimus* (4) *A. philippinensis* (5) *A. stephensi* (6) *A. sundatus* and (7) *A. leucophylla*. The areas of distribution of these mosquitoes are different. *A. fluviatilis* and *A. minimus* are found in the foot-hill regions; *A. sundatus* and *A. stephensi* are found in the coastal regions; and *A. culicifacies* and *A. philippinensis* are found in the plains. An accurate guide to the identification of the known species of *Anopheles* mosquitoes in India may be found in Heath Bulletin No.10 entitled: “Synopsis Table for the Identification of the Anopheles Mosquitoes in India (6).”

(2) Culex

Mosquitoes of the genus Culex are the common "nuisance mosquitoes" which are terrible pests of man. An important member of this group is Culex fatigans, the vector of Bancroftian filariasis in India. Culex fatigans is essentially a domestic species and is found everywhere in India and in and around dwellings. Rapid urbanization and industrialization without adequate drainage facilities are responsible for its increased spread. It breeds profusely in dirty water collections, viz. stagnant drains, cesspools, septic tanks, burrow pits, and in fact, in all types of water collection. Culex fatigans is a strong-winged mosquito; its dispersal has been found to be 11 km in the rural areas of Delhi (7). The species is highly anthropophilic. It enters the houses at dusk and reaches maximum density by midnight. The peak biting time is about midnight. Legs, particularly below the knee are the preferred landing sites. During day, it may be seen resting indoors on walls, underneath furniture, inside empty pots and in dark corners.

(3) Aedes (Stegomyia)

Aedes mosquitoes are easily distinguished by white stripes on a black body. Because of the striped or banded character of their legs, they are sometimes referred to as "tiger mosquitoes". Important members of this group of mosquitoes are: Aedes aegypti, Aedes vittatus and Aedes albopictus. Aedes mosquitoes are most abundant during rainy season. Aedes aegypti occupies a very special position in preventive medicine. It is the first proved vector of a virus disease – yellow fever. Aedes aegypti is widely distributed in India. It breeds in artificial accumulations of water in and around human dwellings, such as water found in discarded tins, broken bottles, fire buckets, flower pots, coconut shells, earthen pots, tree holes and the like. It lays eggs singly, and the eggs are cigar-shaped. The females are tireless biters, and they bite chiefly during the day. They do not fly over long distances – usually less than 100 metres (110 yards). This factor facilitates its eradication. Under the WHO International Health Regulations (IHR), all international airports and seaports are kept free from all types of mosquitoes for a distance of 400 metres around the perimeter of the ports. Under the International Health Regulations, Aedes aegypti index is defined as "the ratio, expressed as percentage, between the number of houses in a limited well-defined area on the premises of which actual breeding of Aedes aegypti are found, and the total number of houses examined in that area" (8). This index is kept at zero at all ports.

(4) Mansonia

The mosquitoes of this genus are big, black or brown mosquitoes with speckling on their wings and legs. The common Indian species are: Mansonia uniformis, Mansonia uniformis, M. indiana and M. longipalis. The mansoniodes mosquitoes are peculiar in their breeding habits. They breed in ponds and take cover in certain aquatic plants, especially the floating types like Pistia stratiotes and water hyacinth. The eggs are laid in star-shaped clusters on the underside of the leaves of these aquatic plants. The larvae and pupae are found attached to the roots of these plants by their siphon tubes; they obtain their all supply from these roots. When about to become adults, the pupae come to the surface of water and the fully formed adults emerge and escape. The control of mansoniodes mosquitoes is easy by the removal or destruction of the aquatic host plants by herbicides.

Habits of mosquitoes

The habits of mosquitoes have been extensively studied by entomologists. A knowledge of these habits is essential from the point of view of controlling the mosquitoes as well as for a proper understanding of the part they play in disease transmission. The following are some of their important habits: (1) FEEDING HABITS: The males never bite: they subsist on plant juices. The females on the contrary are haematophagous. They require a blood meal, once in 2-3 days for the development of eggs. The females differ in their feeding habits. Some species (arthropophilic) prefer human blood, some (zoophilic) prefer animal blood, and some indifferent in their choice and feed on both man and animals. (2) TIME OF BITING: In general mosquitoes bite in the evening or in the early part of the night, but there are great variations among the species. (3) RESTING HABITS: Mosquitoes oviposit themselves during the day in dark and cool corners. Some rest indoors (endophilic), and some outdoors (exophilic). The indoor resting places are usually the dark corners of houses, upper part of walls, behind pictures and under furniture. The outdoor resting places are usually the vegetation, shrubs, tree holes, cattle sheds and wells. (4) BREEDING HABITS: In general, the ontophilic species prefer clean water for breeding; the culicines prefer dirty and polluted water; the aedes prefer artificial collections of water. The mansoniodes breed in water containing certain types of aquatic vegetation. (5) HIBERNATION: Mosquitoes are known to hibernate in the adult stage when the environmental conditions are not favourable. Severe winters are tolerated by hibernation. (6) DISPERSAL: Mosquitoes do not generally fly far from the place where they breed unless swept by currents of wind. The range of flight varies with the species, and may range up to 11 km. Aircrafts and ships have increased the possibility of the dispersal of mosquitoes from country to country, and have created fresh problems of public health. The danger of introduction of mosquitoes infected with yellow fever into
mosquitoes is to eliminate their breeding places. This is known as "source reduction", and comprises minor engineering methods such as filling, levelling and drainage of breeding places; and water management (such as intermittent irrigation). These are proven methods of larval control. Source reduction also implies rendering the water unsuitable for mosquito breeding, as for example, changing the salinity of water. Source reduction requires an accurate knowledge of the breeding habits of mosquitoes. If Culex mosquitoes are a problem, there should be a programme for the abolition of domestic and peridomestic sources of breeding such as cesspools and open ditches, and arrangements should be made for adequate collection, removal and disposal of sewage and waste water. If Aedes mosquitoes are a problem, the environment should be cleaned up and got rid of water holding containers such as discarded tins, empty pots, broken bottles, coconut shells and similar other artificial collections of water. If Anopheles mosquitoes are a problem, their breeding places should be looked for and abolished by appropriate engineering measures such as filling and drainage. If Mansonia mosquitoes are a problem, the aquatic plants to which the larvae attach themselves should be removed or destroyed by herbicides. Source reduction methods generally produce results that are permanent.

(b) Chemical control
The commonly used larvicides are:
(i) Mineral oils
(ii) Paris green
(iii) Synthetic insecticides.

(i) Mineral oils: The application of oil to water is one of the oldest known mosquito control measure. The oils most widely used are the diesel oil, fuel oil, kerosene and various fractions of crude oils. Special oils (e.g., Mosquito Larvicidal Oil) are also available. Oil kills larvae and pupae within a short time after application. When applied on water, oil spreads and forms a thin film, which cuts off the air supply to the mosquito larva and pupae. Oil probably has also a specific toxic action on these insect stages. The usual application rate for oils is 40 to 90 litres per hectare (9). Since the life cycle of a mosquito occupies about 8 days, it is customary to apply oil once a week on all breeding places. Oil has also certain disadvantages, it renders water unfit for drinking; it kills fish. Nevertheless, oil is eminently suited for the control of mosquito larvae.

(ii) Paris green: Paris green or copper acetatevanadate is an emerald green, micro-crystalline powder practically insoluble in water. A good sample of paris green must contain 50 per cent anhydrous oxide. Paris green is a stomach poison and to be effective it must be ingested by the larvae. Paris green kills mostly the Anopheles larvae because they are surface-feeders. Bottom-feeding larvae are also killed when paris green is applied as a special granular formulation (9). Paris green is applied at 2 per cent dust which is prepared by mixing 2 kg of paris green and 98 kg of a diluent such as soapstone powder or slaked lime in a "rotary mixer". The resulting mixture must be fine with the size of the particles ranging from 20–25 microns. The dusting is accomplished by hand blowers or rotary blowers.

The recommended dose is 1 kg of actual paris green per hectare of water surface (9). In the dosage applied, paris green does not harm fish, man or domestic animals.
(iii) Synthetic insecticides: Fenthion, Chlorpyrifos, and Abate are the most effective larvicides (10). These organophosphorous compounds hydrolyze quickly in water. Abate at a concentration of 1.0 ppm has been found to be a very effective larvicide, and also the least toxic. Dosage of these toxicants are given in Table 6. The organochlorine compounds (e.g., DDT, HCH) are not recommended for larviciding operations because of their long residual effect, water contamination and increased risk of developing resistance in the vector mosquitoes.

Biological control
A wide range of small fish feed readily on mosquito larvae. The best known are the Gambusia affinis and Lebister reticulatus (sometimes known as Barbados Millions). These fish can be used in burrow pits, sewage oxidation ponds, ornamental ponds, cisterns and farm ponds. In recent years, there has been a revival of interest in the biological control of mosquitoes through the use of fish (11). It is however recognized that biological control can be effective only when used in conjunction with other methods.

2. ANTI-ADULT MEASURES

(a) Residual sprays
Adult mosquitoes are most commonly controlled by spraying houses with residual insecticides. DDT is the insecticide of choice and dosages of 1–2 grams of pure DDT per sq. metre are applied 1–3 times a year to walls and other surfaces where mosquitoes rest. In areas where DDT resistance is encountered, malathion and propoxur (OMS–33), and to a lesser extent gamma–HCH (lindane) are recommended (12). Dosages and average duration of effectiveness are as given in Table 7.

Resistance to insecticides has become common among mosquitoes, especially after several years of exposure. Resistance to organophosphorus insecticides is also becoming widespread. It is essential that periodic tests should be made to determine the susceptibility of different species of mosquitoes to the various insecticides so that only potent insecticides can be applied.

(b) Space sprays
Space sprays are those where the insecticidal formulation is sprayed into the atmosphere in the form of a mist or fog to kill insects. The common space sprays are: (i) Pyrethrum extract: An extract of pyrethrum flowers is an excellent space spray. The active principle (pyrethrin) is a nerve poison and kills insects instantly on mere contact. Pyrethrum is sprayed at a dosage of 1 oz of the spray solution (containing 0.1 percent of the active principle, pyrethrin) per 1,000 C. ft. of space. The doors and windows are kept closed for half an hour. For domestic purposes, the hand gun with a fine nozzle is all that is necessary, but for application on a large scale, power sprayers or "aerial" dispensers may be needed. Pyrethrum sprays are effective in reducing the number of mosquitoes but the reduction is only temporary since it has no residual action. Reinfestation from outside sources generally occurs within a short time. (ii) Residual Insecticides: New equipment has been developed for ULV (ultra low volume) space spraying. The most extensively used insecticides are malathion and fenitrothion for ULV fogging (13).

(c) Genetic control (14, 15)
In recent years, control of mosquitoes by genetic methods such as sterile male technique, cytoplasmic incompatibility, chromosomal translocations, sex distortion, and gene replacement have been explored. Their use is still in the "Research Phase". These techniques have great potential in mosquito control (3). They also have certain advantages over chemical methods, being cheaper and potentially more efficient and above all not subject to vector resistance.

3. PROTECTION AGAINST MOSQUITO BITES

(a) Mosquito net
The mosquito net offers protection against mosquito bites during sleep. The material of the net should be white, to allow easy detection of mosquitoes. The top as well as the sides of the net should be of netting. The best pattern is the rectangular net. There should not be a single hole or rent in the net. The size of the openings in the net is of utmost importance – the size should not exceed 0.0475 inch in any diameter. The number of holes in one square inch is usually 150.

(b) Screening
Screening of buildings with copper or bronze gauze having 16 meshes to the inch is recommended. The aperture should not be larger than 0.0475 inch. Screening of buildings is costly, but gives excellent results.

(c) Repellents
Diethyltoluamide (deet) has been found to be an outstanding all-purpose repellent (10). It has been found to remain active against C. fatigans for 18-20 hours. There are others also which are effective: indalone, dimethyl phthalate, dimethyl carinate, ethyl hexanoate, etc. Repellents or culefuges are used mainly for application on the skin, and their chief advantage is the short duration of protection.
HOUSEFLIES

Houseflies are the commonest and most familiar of all insects which live close to man. They occur in abundance all the year round in India. The majority of house–breeding flies in India are non-biting. The most important of these are: Musca domestica, M. vicina, M. nebulo and M. sorbens (16). Houseflies should be regarded as a sign of insanitation, and their number as an index of that insanitation.

General characters

The common housefly (M. domestica) is mouse-grey in colour. The body is divided into head, thorax and abdomen. (1) HEAD: The head bears a pair of antennae, a pair of large compound eyes and a retinaculum proboscis, which is adapted for sucking liquid foods. The eyes of the male are close together; those of the female are set apart widely. (2) THORAX: The thorax is marked with 2 to 4 dark longitudinal stripes, which is characteristic of the genus, musca. The thorax bears a pair of wings and three pairs of legs. Each leg is provided with a pair of pads which enables the fly to walk on highly polished surfaces. The legs and the body are covered with numerous short and stiff hairs, called the setae, which secrete a sticky substance. (3) ABDOMEN: The abdomen is segmented and shows light and dark markings.

Life history

The housefly undergoes a complete metamorphosis with four stages in its life cycle: egg, larva (maggot), pupa and adult (Fig. 3).

(1) EGG: The female lays from about 120 to 150 eggs at one sitting in moist decaying organic matter such as human and animal excreta, manure heaps, garbage and vegetable refuse. The Indian M. domestica and M. vicina breed profusely in human excreta. The eggs are pearly-white in colour and about 1 mm long. They can be readily seen by the naked eye. The fly lays from 600 to 900 eggs during her life time. The eggs hatch in 8 to 24 hours; during summer, in India, they may hatch within 3 hours. (2) LARVA: The larvae or maggots measure 1 to 2 mm in length at birth. They are white, segmented and footless with a narrow anterior end, and a broad posterior end. They eat voraciously and molt twice in the course of development. The full grown larva may measure up to 12 mm in length. The larvae resent light; they bury themselves under manure heaps. When about to pupate, they migrate to dry outer regions. The larval period lasts from 2 to 7 days, but this stage may be prolonged in cold weather. (3) PUPA: The pupae are dark-brown and barrel shaped and measure about quarter of an inch. The pupal stage in the tropics occupies 3 to 6 days. In winter months, the pupal stage may be considerably prolonged. (4) ADULT: The complete life cycle from egg to adult may take 5 to 6 days during summer in India, but at other times it may take 8 to 20 days. Flies do not generally live longer than 15 days in summer and 20 days during winter.

Habits

The habits of houseflies make it eminently suited for the spread of disease. (1) BREEDING HABITS: The most important breeding places of flies in order of importance are: (a) fresh horse manure (b) human excreta (c) manure of other animals (d) garbage (e) decaying fruits and vegetables which contain organic matter and (g) yard where liquid wastes are spilled. (2) FEEDING HABITS: The housefly does not bite. It is attracted to food by its sense of smell. It cannot eat solid foods; it vomits on solid food to make a solution of it and sucks in a liquid state. Adult flies delight in stoup, faeces, discharges from wounds and open sores. (3) RESTLESSNESS: The fly is a restless insect and moves back and forth between food and filth. This helps in the spread of infection mechanically. (4) VOMIT DROP: The fly vomits frequently. The "vomit drop" is a small culture of disease agents. (5) DEFEICATION: The houseflies have the habit of defecating constantly all the day. Thus it deposits countless bacteria on exposed food. (6) RESTING HABITS: Flies have a tendency to rest on vertical surfaces and hanging objects. They have a tendency to fly towards light. (7) DISPERSAL: Normally houseflies remain close to their breeding places, but they disperse frequently up to 4 miles, and sometimes even more from the point of their origin.

Transmission of disease

Flies are potential vectors of many diseases: typhoid and paratyphoid fevers, diarrhoea and dysenteries, cholera, and gastroenteritis, amoebiasis, Leishmaniasis, intestinal infestations, poliomyelitis, conjunctivitis, trachoma, onchocerciasis, trachoma, yaws, in fact, most diseases that can be spread by mechanical transmission.

Flies transmit disease in the following ways: (1) MECHANICAL TRANSMISSION: Houseflies are exceptionally efficient mechanical spreaders of disease. They transport microorganisms on their feet and hairy legs. Pathogenic organisms, ova and cysts have been recovered from the bodies of the common housefly. Houseflies are therefore called "porters of infection". (2) VOMIT DROPPING: The regurgitated stomach contents or "vomit drop" is a rich bacterial culture. By its habit of frequent vomiting, the housefly infects food and thereby transmits disease. (3) DEFEICATION: The excrement of housefly has been found to contain numerous microorganisms as well as ova and ova of intestinal parasites. By its habit of constant defecation, the housefly spreads these diseases.

FLY CONTROL MEASURES

1. Environmental control

The best way to control houseflies is to eliminate their breeding places and to bring about an overall improvement in the environmental sanitation on a community-wide basis. This, in effect, implies the following: (1) storing garbage, kitchen wastes and other refuse in bins with tight lids, pending disposal. (2) Efficient collection, removal and disposal of refuse by incineration, composting or sanitary landfill. (5) Provision of sanitary latrines, e.g., pit privies.
septic tanks, water-seal latrines and sanitary system. (4) stopping open air defecation. (5) sanitary disposal of animal excreta, and (6) growing up general sanitation. A clean house with clean surroundings is the best answer to the fly problem.

2. Insecticidal control (17,18)

(1) RESIDUAL SPRAYS: Since it first showed resistance to DDT in 1948, M. domestica has developed resistance to the other organo-chlorine compounds as well as to organophosphorus and carbamate pesticides. Susceptible flies may be killed by DDT (1%), dieldrin (0.5%), heptachlor (0.3%), and chlordecone (2%). Sprayed at about 5 litres per 100 square metres of surface; for flies resistant to these, diazinon (2%) dimethoate (2.5%), fenitrothion (2.5%), malathion (5%), or rotenone (5%) may be used. The addition of sugar to insecticidal formulations enhances their effectiveness. Special care should be taken to prevent contamination of food or water during spraying operations. (2) BAITS: Baits may be solid or liquid. Poisoned baits containing 1% or 2% insecticide, malathion, dichlorvos, rotenone, and dimethoate have been tried with success. Liquid baits containing 0.1 to 0.2% of the same insecticides and 10% per cent sugar water have given good results. The cheapest bait is one that is made by mixing 3 teaspoons of commercial forzatisf with one pint of water or milk to which is added a little sugar. (3) CORDS AND RIBBONS: Cords and strips impregnated with diazinon, fenithion, or dimethoate have been tried with success. These are hung like feathers from ceilings. The period of effectiveness ranges from 1 to 6 months. (4) SPACE SPRAYS: Space sprays containing pyrethrum and DDT or HCH are available commercially. These may be applied indoors or outdoors using hand or power sprayers. Space sprays in general have little or no residual action. They produce only a temporary effect on adult fly populations; consequently, repeated applications are necessary. (5) LARVICIDES: Insecticides such as 0.5% diazinon, 2% dichlorvos, or 1% rotenone applied at the rate of 28-56 litres per 100 sq. metres have been used for the treatment of fly breeding places. The reason why they cause or accelerate the development of resistance. In summary, it may be stated that insecticides, at best, are only a supplement, but not a substitute for sanitation.

3. Fly papers

 Sticky fly papers are useful adjuncts to other methods of control. These papers can be easily made by mixing 2 lbs of resin and one pint of castor oil which should be heated together until the mixture resembles molasses. This should, while hot, be smeared on paper by using an ordinary paint brush. The adhesive mixture can also be applied to strips of wire and hung up in places where flies abound. Although a slight reduction of flies may occur, no lasting benefits will result from the use of fly papers.

4. Protection against flies

Screening of houses, hospitals, food markets, restaurants and all other similar establishments will give considerable relief from houseflies. Screens with 14 meshes to the inch will keep out houseflies but fine screens will also keep out the other insects. Screening is expensive for general use.

5. Health education

It is difficult to achieve fly control without the willing cooperation of the people. A "fly consciousness" should be created among the people, through health education. Fly control campaigns require organized individual and community efforts to combat the insect. The most successful health programme is it only through health education that people can be motivated with a desire to get rid of flies permanently.

SANDFLIES

Sandflies are small insects, light or dark-brown in colour. They are smaller than mosquitoes, measuring 1.5 to 2.5 mm in length with their bodies and wings densely clothed with hair. Some 30 species of sand-flies have been recorded in India. The important ones are Phlebotomus argentipes, P papatasi, P sergenti, and Sergentomyia punjebicensis. Our knowledge of the Indian sandflies is meagre, and needs more studies (19).

General characters

The body of a sandfly is divided into head, thorax and abdomen. (1) HEAD: The head bears a pair of long, slender and hairy antennae; palpi and a proboscis. Only the females bite, the males live on vegetable juices. (2) THORAX: The thorax bears a pair of wings and three pairs of legs. The wings are upright, lanceolate in shape and densely hairy. The second longitudinal vein on the wing branches twice, the first branching takes place in the middle of the wing. This is a characteristic feature of the genus, Phlebotomus. The legs are long and slender and out of proportion to the size of the body. (3) ABDOMEN: The abdomen has 10 segments and is covered with hair. In the female, the tip of the abdomen is rounded; in the male, there are spines, which are conspicuous and attached to the last abdominal segment.

Sandflies may be distinguished from mosquitoes by the following characteristics: (1) Size: Sandflies are smaller than mosquitoes. (2) Wings: The wings of the sandfly are up-right and lanceolate in shape; the second longitudinal vein branches twice, the first branching taking place in the middle of the wing. (3) Legs: The legs of the sandfly are longer compared with the size of the body. (4) Heads: The heads of sandflies are elongated. Insect. (5) Hopping: Sandflies hop about, and do not fly by choice.

Life history

The life history of the sandfly is characterised by complete metamorphosis, having four stages: egg, larva, pupa and adult (Fig. 4).

(1) EGG: The eggs are laid in damp dark places in the vicinity of cattle sheds and poultry. The eggs are comparatively large, and torpedo-shaped with longitudinal wavy lines on the outside. The eggs hatch within 7 days.

(2) LARVA: The larvae are hairy maggots with a distinct head, thorax, and abdomen. The last abdominal segment carries two pairs of long stout hairs; one pair is remarkably long. The larva feeds on decaying organic matter and becomes pupal about the middle of the third week. (3) PUPA: The pupa stage lasts for about 1 week. (4) ADULT: The average life of a sandfly is about 2 weeks.

Habits

Sandflies are troublesome nocturnal pests. Their bite is irritating and painful, while their presence is scarcely observed. They infest dwellings during night, and take shelter during day in holes and crevices in walls, holes in trees, dark rooms, stables and store rooms. The females...
found in African continent. Regions infested with tsetse flies are called "fly belts." For centuries, the tsetse fly has ravaged vast areas of tropical Africa, and has caused economic and social progress; it continues to be a menace even today.

Life history

The life history of the tsetse fly is somewhat abnormal. The female does not lay eggs, but gives birth to a living larva, one at a time. An adult female produces only a few offspring in its life time. Soon after birth the larva crawls away to a suitable place and buries itself in the earth, usually at a depth of an inch or so beneath the surface. Pupation then takes place, within a few hours. The pupal stage lasts for 20–40 days. At the end of the pupal stage, the adult fly emerges. The tsetse lives less than 100 days.

Species and habits

More than 30 species of the Glossinae have been recognized, but only five species are dangerous to man. They are: G. palpalis, G. tachinoides, G. morsitans, and G. pallidipes. The first two species are sometimes called "rinderpest species" because they inhabit the woodland vegetation near water courses; the latter two are called "savannah species" because they prefer to live and breed in woodland vegetation in savannah country.

Tsetse flies attack man, animals, wild game of all kinds, birds, lizards and snakes. Both the sexes bite, mainly during day. The riverine species (e.g., G. palpalis and G. tachinoides) have a distinct attraction to man; the savannah species prefer to feed on game rather than man. Tsetse flies rarely enter houses, but they are known to follow travellers both by road and rail for considerable distance in order to obtain a blood meal. Tsetse flies are vectors of trypanosomiasis or "sleeping sickness." The disease affects man, domestic animals and wild game – being particularly lethal to man, and his domestic stock.

Control of tsetse flies

There are four main techniques in the control of tsetse flies: (1) INSECTICIDES: Resistance to insecticides has not been reported in Glossina. At present, DDT (25%) and dieldrin (18–20%) are the most commonly used pesticides for tsetse fly control (17). The insecticide is applied from aircraft when large areas are to be covered quickly. (2) CLEARING OF VEGETATION: Clearing of vegetation where tsetse flies live and breed is now the technique most widely adopted for controlling tsetse flies. Used alone, this method gives slow results but in conjunction with the application of residual insecticides, it has given a speedy reduction of flies. (3) GAME DESTRUCTION: Large tracts of Africa have been cleared of the tsetse flies by the destruction of wild game. This method is now given up. (4) GENETIC CONTROL: Currently, research is centred

alone bite, as they require a blood meal every third or fourth day for oviposition. Sandflies are incapable of flying over long distances; they merely hop about from one place to another. Sandflies are generally confined to within 50 yards of their breeding places.

</table>

Control of sandflies

Sandflies are easily controlled because they do not move long distances from the place of their breeding. (1) INSECTICIDES: Resistance to DDT has not been demonstrated. A single application of 1 to 2 g/m² of DDT or 0.25 g/m² of lindane has been found effective in reducing sandflies. DDT residue may remain effective for a period of 1 to 2 years, and lindane only for a period of 8 months (17). Spraying should be done in the human dwellings, cattle sheds and other places. (2) SANITATION: Sanitation measures such as removal of shrubs and vegetation within 50 yards of human dwellings, filling up cracks and crevices in walls and floors, and location of cattle sheds and poultry houses at a fair distance from human habitations should receive attention.

TSETSE FLIES

Tsetse flies or the Glossinae are bloodsucking flies, which present a general resemblance to the common housefly. They are yellow or dark-brown in colour, and measure about half an inch long. Their wings, when folded, overlap each other like the blades of a scissor. They have a proboscis which is rigid and non-retractile and adapted for piercing the skin and sucking blood. Tsetse flies are only
round genetic control of tsetse flies using the "sterile male release" technique (20).

BLACKFLIES

Blackflies or simuliidae are small robust flies with short stout legs, large broad wings and a short proboscis (Fig. 6). They are very often all black. Simulium indicum is the Indian species (21). Blackflies attack domestic animals and man and suck blood. They are vectors of onchocerciasis in Africa, Mexico, and Central and South America. The eggs are laid on submerged stones and water weeds. The larvae are aquatic; they fly themselves to stones or plants, usually at a depth of 1 foot. The larval stage occupies 3 to 4 weeks. They pupate in water; the pupal stage occupies 1 to 3 weeks. In India, simuliiiae breed in hill streams. Control of the adult fly is difficult, because the range of the fly is about 100 miles. Therefore, the attack is levelled at the nai. Nai is used which kills the blackfly/ larvae without causing harmful effects to mammals or other aquatic fauna. It is added to river water in weekly doses of 0.05 to 0.1 mg/litre over a period of 10 minutes (22).

FIG. 6

Simulium

LICE

Lice are small wingless ectoparasites of mammals and birds. They bite severely and are annoying pests. The lice that infest man are of three kinds: head louse (Pediculus capitis), body louse (Pediculus corporis), and pubic or crab louse (Phthirius pubis). Human lice occur in all parts of the world wherever standards of hygiene are low, but people in colder climates are affected more frequently than those in warmer regions. Infestation by lice is called pediculosis.

Head and body lice

The head and body lice differ very little in structure except in their habitat. The head lice inhabit the hairs of the scalp, and the body lice occur mainly in the seams of clothing and on the bodies of the hosts. The body of a louse is flattened dorso-ventrally, and is divided into head, thorax and abdomen. (1) HEAD: The head is pointed in front and bears a pair of 5-pointed antennae. The mouth parts are adapted for sucking blood. (2) THORAX: The thorax is a fleshy mass and is shaped somewhat like a square. Three pairs of legs are attached ventrally to the thorax. The legs are strongly developed and are provided with claws which help the insect to cling to the hair and clothing. (3) ABDOMEN: The abdomen is elongated and consists of 9 segments. The last abdominal segment is pointed in the case of males, and bilobed in the case of females.

Life history

There are three stages in the life history of lice: egg, larva, and adult. Metamorphosis is gradual (Fig. 7).

(1) EGG: The eggs, called "nits" are laid singly or in groups, firmly attached to the hair or seams of clothing by a cementing substance. The eggs are small, white ovoid bodies, pointed at one end and truncated and pit at the other end. A female louse may lay from 300 eggs, at the rate of 4 or 9 eggs a day. Under favourable conditions of temperature, the eggs will hatch in 6 to 9 days. The eggs will not hatch if the temperature is below 22 deg. C (71.6 deg. F.). (2) LARVA OR NYPH. The larva looks very much like an adult, except for its smaller size. It feeds on the host and develops into an adult after passing through 3 molts. The larval stage may take 10 to 15 days. (3) ADULT: The entire life cycle from the laying of an egg to the appearance of the adult louse takes about 15 to 17 days under favourable conditions. Adult lice live from 30 to 50 days.

Dissemination

(1) DIRECT CONTACT: Lice are disseminated by close contacts with lousy or infested persons. overcrowding provides an excellent opportunity, for the direct transference of lice from one person to another. Children get easily infested at school when they heads come together at work or play. (2) INDIRECT CONTACT: Lice may also be acquired from clothing, bedding, combs or brushes used by lousy persons. Lice have been seen to be blown by puffs of wind from heavily infested persons. Lice tends to leave the host whose temperature rises above or falls below the normal.

Lice and disease

Lice are vectors of the following diseases:

<table>

Crab louse

The crab louse or pubic louse (Phthirius pubis) is generally found in the pubic and perineal region, but at times it may occur in the other parts of the body as well. It adheres close to the skin, and its removal is a matter of difficulty. The crab louse has a characteristic body form, and is readily recognized by (1) its small size and square body,
FLEAS

Fleas are small, bilaterally compressed, wingless insects with a hard chitinized exoskeleton and covered with backwardly directed strong bristles. They are blood-sucking ecto-parasites of mammals and birds. The fleas found on one particular kind of animal host will not usually seek the blood of another species of animal, unless compelled by necessity.

Types of fleas

More than a thousand different species of fleas have been described, and 37 species are known to occur in India. The fleas of importance in public health are:

1. Rat fleas
   (Oriental)
   - Xenopsylla cheopis
   - Xenopsylla spinipes

2. Rat fleas
   (Black house)
   - Notoctes maculata

3. Human fleas
   - Pulvillus

4. Dog and cat fleas
   - Ctenocephalus canis
   - Ctenocephalus felis

5. Sand fleas
   (Jigger or chigoe fleas)
   - Tunga penetrans

The rat fleas are of greatest importance because they are vectors of plague and typhus. Xenopsylla cheopis is rare in India; it occurs in temperate zones. The human flea, Pulvillus, has a wide host range; in addition to man, it infests commensal rats, pigs, cats, dogs and foxes. The cat and dog fleas occur almost everywhere. They occur not only on the specific hosts, the cat and dog, but also on other animals. They are prone to attack man. The sand flea, Tunga penetrans occurs in the tropical regions of Africa and America.

Rat fleas

The body of a flea is divided into head, thorax and abdomen. (1) HEAD: The head is conical in shape and is attached to the thorax without a neck. The head bears short, piercing mouth parts which are conspicuous and project downwards from the head. The mouth parts are adapted for piercing and sucking blood. (2) THORAX: The thorax is composed of three segments – the prothorax, mesothorax and metathorax. There are three pairs of strong legs attached to the thorax. (3) ABDOMEN: The abdomen consists of 10 segments. The sexes are easily distinguished. In the male, there is a coiled structure, the penis, in the abdomen. In the female, there is a short, stump-like structure, the spermatheca, in the posterior part of the abdomen. The shape of the spermatheca helps in the identification of the species.

Life history

There are four stages in the life history of fleas: eggs, larvae, pupa and adult. Metamorphosis is complete (Fig. 9).

(1) EGG: The eggs are small (0.5 mm), ovoid and white in colour. They are deposited among the hairs of the animal host or in and near the nests or haunts of its host. A female may lay 300–400 eggs in its life time – 2 to 6 per day more at a time. The eggs hatch in 2 to 7 days, depending upon temperature.

(2) LARVA: The larvae are small, legless caterpillars, whitish in colour, and bear sparse long hair on their bodies. They are found in the dust and debris, in or near nests or lairs of the host. They feed on organic matter and grow in the faeces of the adult flea. There are three larval stages; the last stage spins a cocoon, to which dust particles adhere. The duration of the larval stage is about 2 weeks.

(3) PUPA: The

Phiphus subis

Control of lice (17.18)

(1) INSECTICidal CONTROL: Insecticides appear to be the only means at present for the control of lice. There are reports that lice have become resistant to many areas to DDT and HCH, and there are some reports of resistance to malathion. It is of utmost importance to monitor periodically louse susceptibility to insecticides to assess which insecticide should be used (15). (a) Heat and crab lice: The present recommended treatment is a lotion containing 0.5% permethrin. The lotion should be left on for 12 to 24 hours when the hair can be washed. Malathion, if correctly used, will kill lice and nits. Dust containing carbaryl is also effective as louse powder. (b) Body Lice: Since lice have become resistant to DDT and HCH, a powder containing 1% permethrin will obviously be the treatment of choice. Dust containing carbaryl may also be used. The powder is applied to the inner surface of the clothing as well as under the body of the persons. "Mass delousing" of large numbers of people is carried out with hand operated dusters. The powder is blown down the neck of the shirt, up the sleeves, and into the loosened trousers from several angles at the front and back. With this type of treatment, the clothing is not removed and about 50 g. (2 ozs.) of the insecticidal powder are required for one person. Normally a single application will eradicate an infestation, but a second application may be made in 7 days to kill louse-bating lice.

(2) PERSONAL HYGIENE: Delousing procedures should be accompanied by improvements in personal hygiene. Lice require very close contact with humans, frequent blood meals and a relatively constant temperature. They cannot survive in communities where people regularly bathe, change and launder their clothes. A daily bath with soap and water is essential in a country like India to prevent lice infestation. Women with long hair should wash and clean their hair frequently. Clothing, towels and sheets should be washed in hot water and soap and pressed with hot iron. Accumulating of clothes and bedding in steam sterilizers may be required for body louse control. The long-term control policy should be based on improvement of personal hygiene, partly by simple health education and also by improving living standards.
pupa develops inside the cocoon. The pupal stage lasts for 1 to 2 weeks, depending upon temperature and other environmental influences. (4) ADULT: The life cycle of a flea may be completed within 3 weeks, under favourable conditions. The fleas live normally for a month or so under tropical conditions. Infected fleas may live for one year, and certain species may survive in the burrow microclimate for as long as 4 years (17).

![Life cycle of rat flea](image)

**FIG. 9** Life cycle of rat flea

**Habits**

Fleas are found on their normal hosts and in the nests, burrows and lairs of their hosts. They are also found in the dwellings, on the ground, in crates and crevices, and under carpets. Both the sexes bite and suck blood. They feed at frequent intervals, usually once a day and sometimes more often. Fleas cannot fly, but they are capable of making vertical jumps of about 4 inches when startled, and about 3 inches when gorged. The distance they can cover by horizontal jumps is less than 6 inches. Fleas are passively transported by (a) their hosts (b) transport vehicles (c) humans — on the person or in the luggage, and (d) the movement of goods like grain, raw cotton, gunny bags, rugs and tiles.

**Flea indices**

The following indices are used in flea surveys:

1. **GENERAL FLEA INDEX**: It is the average number of fleas of all species per rodent.
2. **SPECIFIC FLEA INDEX**: (X cheopis index; X. c. index, etc.) It is the average number of fleas of each species, found per rodent.
3. **PERCENTAGE INCIDENCE OF FLEA SPECIES**: It is the percentage of fleas of each species, found per rodent.
4. **RODENT INFESTATION RATE**: It is the percentage of rodents infested with the various flea species.

Flea indices do not in themselves indicate an imminent plague epidemic. But flea indices serve as useful indicators of the potential explosiveness of the situation, should a plague outbreak occur in an endemic area (23). Specific flea indices are more significant than are overall flea indices.

**Fleas and human disease**

Fleas are known to transmit the following diseases:

**MODE OF TRANSMISSION**: Fleas convey disease by:

1. Biting: The chief method of transmission, in the case of plague, is by the bite of hungry 'blocked' fleas. Some fleas which ingest plague bacilli become blocked due to the multiplication of plague bacilli in their prevermiculums or stomach. Fleas affected in this way are called 'blocked' fleas. The blockage of the food passage renders the flea unable to obtain further blood feeds. Because of hunger, the flea begins to bite more ferociously and makes frantic efforts to suck blood. Each time it bites, instead of sucking blood, it injects plague bacilli into the wound. Such 'blocked' fleas play a great role in the spread of plague.
2. Mechanical transmission: Mechanical transmission takes place from the proboscis of the flea, which had recently fed on an infected rodent. (3) Feces: The fleas are apt to defecate while feeding. The fecal drop of infected fleas may contain numerous bacilli. When the host scratches over the flea-infested area, there is direct inoculation of the infective agent into the angry spot.

**Control of fleas**

1. **INSECTICIDAL CONTROL**: The cheapest and most widely used formulation has been 10 per cent DDT dust. As the rodents pass over the dust, they pick it up on their fur where it kills the fleas. In a number of plague areas, the rat fleas have developed resistance to DDT and/or to gamma-HCH and dieldrin. In such areas, carbaryl or diazinon (2%) or malathion (5%) should prove effective (9). The sprays should be applied to floors and walls up to a height of about 1 ft. Patch dusting with insecticides has also been found to be an effective method of controlling fleas. The insecticidal powder is dusted over rat runs, under gunny bags, and other harbourage areas. The insecticidal dust should also be blown into the rodent burrows with the help of dust blowers at about 30 g. per burrow. Animal hosts like cats and dogs and their quarters and premises should also be treated with insecticidal dusts, sprays or dips.
2. **REPELLENTS**: Diethyltoluamide is an efficient flea repellent. Clogging impregnated with diethyltoluamide repels fleas for more than a week. Benzyl benzoate is also a good flea repellent. (3) RODENT CONTROL: This control should be followed by rodent control. This subject is treated elsewhere in this chapter.

**SAND FLEA**

Sand fleas occur in the tropical regions of Africa and America. They are also known as Jigger or Chigoe fleas. Of particular importance is the sand flea, Tunga penetrans. The fertilized female burrows into the skin of the foot, often beneath the nail and causes ulcers. Tetanus and gas gangrene frequently occur because of secondary infection. *T. penetrans* has been recorded in the western parts of India; it has not yet been able to gain foothold in India. It flourishes best in sandy soil. Its hosts are usually domestic animals (Fig. 10).

![Sand Flea](image)

**FIG. 10** Sand Flea
REDUVID BUGS

Reduvid bugs, also known as cone-nose bugs, are vectors of Chagas' disease in Mexico and Central and South America. All are of large size, about an inch or more in length. Adults have wings. These bugs live exclusively on the blood of animals including man and transmit Trypanosoma cruzi, the causative agent of Chagas' disease. These bugs occur in India (21), but are not incriminated in the transmission of any disease. These bugs frequently attack man and their bites may cause intense itching, nausea, flushed face, palpitation of the heart, etc. (Fig. 11).

FIG. 11  Reduvid bug

These bugs live in cracks, fissures and other hiding places in walls and ceilings of human dwellings and in animal habitations and nests. They emerge only to feed and then retreat into their hiding places. Where housing is primitive, conditions may be ideal for these bugs. Residual spraying with HCH (0.5 gm/m² or dieldrin (1 gm/m²) is commonly used for control of these bugs (17).

TICKS AND MITES

Ticks and mites comprise one of the largest and most important orders (Acari) of the phylum Arthropod. They are ectoparasites of vertebrate animals, and they all suck blood.

Ticks

Ticks are of two kinds: hard ticks (Ixodidae) and soft ticks (Argasidae).

The body of a tick is oval in shape and is not distinctly separated into head, thorax and abdomen. They have four pairs of legs, and no antennae. The hard ticks are covered on their dorsal surface by a chitinous shield, called scutum, this in the male covers the entire back, and in the female only a small part in front. The scutum or dorsal shield is absent in soft ticks. Hard ticks have a "head" or capitulum at anterior end; soft ticks have a head on underside, which is entirely invisible from above (Fig. 12 & 13). The males are generally smaller than females. The hard ticks feed both night and day and cannot withstand starvation; the soft ticks, on the other hand, feed at night and can withstand starvation for several months. The hard ticks are always found on their hosts; the soft ticks hide in cracks and crevices during the day and emerge at night to feed on the host. The common hard ticks which infest domestic animals such as dogs and cattle in India are: Dermacentor, Haemaphysalis, Hyalomma, Rhizophalus and Boophilus. From the medical standpoint, the soft tick of importance is Ornithodorus moubata, which transmits relapsing fever.

Life history

There are four stages in the life history of ticks: egg, larva, nymph and adult. (1) EGG: Hard ticks lay eggs in a few hundreds or even thousands, all at one time, after which the female is exhausted and dies. The soft ticks lay eggs in batches of 20 to 100 over a long period. The eggs are deposited on the ground and hatch in 1 to 3 weeks. (2) LARVA: The larva of the tick possesses 3 pairs of legs, it lies in wait among grass and herbage till a suitable host appears to which it attaches itself. After a blood meal, it drops off, and in course of time it molts to become a nymph. The duration of the larval stage may vary from 3 to 13 days. (3) NYMPH: The nymph resembles the adult in having 4 pairs of legs, but it has no genital pore. The nymphs are all blood suckers, and they attach themselves to suitable hosts for a blood meal. There are 5 nymphal stages in the life history of soft ticks. (4) ADULT: The duration of the life cycle from egg to adult is about 2 months in the case of hard ticks, and from 9 to 10 months in the case of soft ticks. Adult ticks may live for a year or more. Soft ticks live longer than hard ticks.

Public health importance

Hard ticks transmit the following diseases:

(a) Tick typhus (Rocky mountain spotted fever)
(b) Viral encephalitis (e.g., Russian spring-summer encephalitis)
(c) Viral fever (e.g., Colorado tick fever)
(d) Viral haemorrhagic fevers (e.g., KFD in India)
(e) Tularemia
(f) Tick paralysis, and
(g) Huenan babesiosis.

Soft ticks transmit:

(a) Q fever
(b) Relapsing fever, and
(c) KFD.
The tick attaches itself to its host by means of its mouth parts. The orostium is burrowed into skin to enable it to suck blood. At the same time saliva is secreted, which contains a neurotoxin. Mature females, especially gravid female ticks, may remain attached for a comparatively long time but the male usually drops off the body after a few days. As the tick feeds, it gradually becomes engorged with blood.

Ticks transmit disease by biting. The larvae and nymphs are also capable of transmitting disease by biting (i.e., infection is maintained trans-stadially). Experiments have also shown transovarian transmission of infection through successive generations.

**Hard and soft ticks compared**

Hard and soft ticks are compared as shown in Table 8.

**Control of ticks and mites**

(1) INSECTICIDAL CONTROL: Great success has been obtained in destroying ticks and mites by the use of modern insecticides. DDT, chlordane, dieldrin, lindane, malathion, and toxaphene at rates of 1 to 2 lbs per acre give effective control. Either dusting or spray formulations can be employed. A thorough knowledge of the habits of a given species of tick must be obtained before planning a control programme. Animals like dogs may be freed of ticks by treating them with insecticidal sprays or dusts. Not only the animals, but also the premises which they frequent should be treated with insecticides (2) ENVIRONMENTAL CONTROL: Cracks and crevices in ground particularly near buildings and paths should be filled up. Animal hosts such as wild rodents and dogs should be reduced. (3) PROTECTION OF WORKERS: Exposed workers should be encouraged to wear protective clothing impregnated with an insect repellent. The best repellents against ticks and mites are indalone, diethyltoluamide and benzyl benzoate. Further, persons working in tick-infested areas should be trained to examine themselves for ticks both during the lunchhour and at the end of work and to remove promptly any ticks found on their person. This is achieved by painting the tick with petrol paraffin or a camel's hair brush with which the dead tick can be brushed off the skin. (25) It may be necessary to extract the head gently with forceps and in that event care should be taken not to break the mouth parts.

**Mites (Chiggers)**

Mites (chiggers) resemble ticks in their general appearance, having 4 pairs of legs and a body not well demarcated into head, thorax and abdomen. From the public health standpoint, two mites are important: (3) the trombiculid mite, and (2) the itch mite (Acarus scabiei).

**TROMBICULID MITES**

These are spider-like arthropods. The important species are *Leptotrombidium deliense* and *L. akamushi* which are vectors of scrub typhus in Asia and South Pacific.

**Life History**

The *life history* of a mite consists of 4 stages (Fig. 14):

- Egg, larva nymph and adult. (1) EGG: Eggs are laid singly; they hatch in about a week. (2) LARVA: The larva is very small, pale orange in colour, and has 3 pairs of legs. It attacks vertebrate hosts (rodsent or man). When gorged with blood, it drops down to the ground for moulting. The larval stage lasts for 1 to 2 weeks. (3) NYMPH: The nymph is brick-red in colour and has 4 pairs of legs. It lives on vegetable juices. The nymphal stage lasts for 1 to 3 weeks. (4) ADULT: The adult male lives in soil. It has 4 pairs of legs, the first pair being the largest. The mite lives for about 6 months.

**Fig. 14**

Life cycle of a mite

**ITCH MITE**

The discovery in 1667 of the itch mite marks scabies as the first disease of man with known cause (20). The itch mite (Sarcopes scabiei or *Acarus scabiei*) is an extremely small, globular arthropod just visible to the naked eye. The female parasite burrows into the epidermis where it breeds and causes the condition known as scabies or itch. Species of the genus sarcoptes also infest animals such as dog, cattle and horse. The human acarus is morphologically indistinguishable from the animal variety but it is quite distinct physiologically. Therefore, animal scabies cannot flourish on the human skin.
General description

The itch mite is just visible to the naked eye, measuring 0.4 mm in size and has a body shaped like a tortoise, rounded above and flattened below. The body surface is thrown into folds and is covered with short bristles. The parasite has two pairs of legs in front, and two pairs behind. The front legs end in long tubular processes known as suckers and the hind legs end in long bristles. The female has suckers on all the legs except the third pair, which distinguishes it from female (Fig. 15).

Fig. 15
Itch mite

Life history

There are four stages in the life history of an itch mite: egg, larva, nymph and adult. (1) EGG: The female burrows within the stratum corneum, and lays eggs in the burrow. A single female may lay up to 30 eggs at the rate of 2 to 3 per day, and ultimately dies at the end of the burrow. The eggs hatch into larvae in 3 to 4 days. (2) LARVA: The larvae are three-legged. They leave the burrows, come to the surface and bore into the hair follicles where they mature. The larvae mature into nymphs in about 3 days. (3) NYMPH: The nymphs develop into adults in 6 to 8 days. (4) ADULT: The life cycle from egg to adult may take 10 to 15 days. The adult mites live for 1 to 2 months.

Mode of spread

(1) CLOSE CONTACT: Scabies is usually transmitted by close contact with an infected person. This is often due to sleeping in the same bed or by children playing with each other or nursing an infected person. Because of close contact, the disease tends to spread through families. Scabies is therefore called a familial or household infection. (2) CONTAMINATED CLOTHES: The disease may be acquired sometimes from contaminated clothes and bed linens.

Site of lesions

The disease classically affects the hands and wrist (63%), the exterior aspect of elbows being next (10.9%). The axillae, buttock, lower abdomen, feet and ankles, palms in infants are all common sites of infestation. The disease also affects the breasts in women and the genitals in men.

Diagnosis of scabies

The main diagnostic features of scabies are: (1) the patient complains of itching which is worse at night, (2) examination reveals follicular lesions at the affected site, (3) secondary infection leads to crusty pustules and papules, (4) the diagnosis is probable if the other members of the household are affected, (5) confirmation of the diagnosis may be made by searching for the parasite in the skin debris under microscope.

Control of scabies

In the control of scabies, it is essential to treat all members of the affected household simultaneously whether or not they appear to be infested. Before commencing the treatment the patient is given a good scrub with soap and hot water. (1) BENZYL BENZOATE: Benzyl benzoate (25 per cent) is an effective scabicicide. It should be applied with a soft brush or shaving brush to every inch of the body below the chin including the soles of the feet and allowed to dry. In the case of babies, the head must also be treated. The application should be repeated after 12 hours, and after a further 12 hours a bath given and all underclothes, clothes and sheets changed and washed. Not more than two applications of benzyl benzoate should be given per week as excessive use can cause an irritant dermatitis (27). (2) HCH: 0.5 to 1.0 per cent strength of gamma-HCH (lindane) in coconut oil or any vegetable oil or vanishing cream is an efficient scabicicide. The preparation should be rubbed on the affected parts of the skin on one or two occasions separated by an interval of 2 to 3 days. (3) TETROMOSOL: A 5 per cent solution of tetromosol is also an efficient scabicicide, three daily applications are recommended (4) SULPHUR OINTMENT: 2.5 to 10 per cent daily for 4 days is a cheap remedy.

CYCLOPS

Cyclops or water flea is a crustacean present in most collections of fresh water. It is a tiny arthropod, not more than 1 mm in length and just visible to the trained eye. It has a pear-shaped semi-transparent body, a forked tail, 2 pairs of antennae, 5 pairs of legs and a small pigmented eye (Fig. 16). It swims in water with characteristic jerky movements. The average life of a cyclops is about 3 months.

Public health importance

(1) Cyclops is the intermediate host of Dracunculiasis or guinea-worm disease. Man acquires infestation by drinking water containing infected cyclops. (2) Cyclops mediates also as one of the intermediate hosts of Chilodonella sp., Diphyllolothrium latum infestation. The disease is rare in India.

Control of cyclops

Cyclops may be controlled by the use of physical, chemical or biological methods (29). (1) PHYSICAL: - (a) Straining: Straining of water through a piece of fine cloth is sufficient to remove cyclops. (b) Boiling: Cyclops is readily killed by heat at 60°C. The physical methods are useful for individual prophylaxis. (2) CHEMICAL: (a) Chlorine. Chlorine destroys
cycloids and larvae of guinea worm in a strength of 5 ppm. This high concentration of chlorine gives an objectionable smell and taste to drinking water. The excess chlorine needs to be removed by dechlorinating agents (21). (b) Lime: Lime at a dosage of 4 gram per gallon of water is found to be very efficient for killing cycloids. (c) Abate: The organophosphorous insecticide, Abate (OMS–786) has been found effective in killing cycloids at a concentration of 1 mg/litre (30). This indicates that Abate is potentially useful in the chemical control of the guinea-worm infection. (3) BIOLOGICAL: Certain kinds of small fish, e.g., barbel fish and gambusia fish have been found to feed on cycloids. These fish were used successfully in eradicating guinea-worm in parts of Karnataka State (31). The most satisfactory and permanent method of controlling cycloids in drinking water is to provide piped water supply or tube wells. Abolition of step wells and provision of sanitary wells should receive attention in rural areas.

INSECTICIDES

Insecticides are substances which are used to kill insects. The word pesticide is a general term that includes insecticides, fungicides, rodenticides, herbicides, disinfectants, repellents, and other chemicals used for the control of pests. The control of arthropod borne diseases by insecticides is one of the greatest triumphs of public health during the 20th century. Insecticides have not only controlled malaria, plague, typhus and other diseases transmitted by insects, but also brought vast economic and social benefits through better health and increased food production.

Insecticides are classified into three groups: contact poisons, stomach poisons and fumigants. CONTACT POISONS are those which kill insects primarily by contact e.g., pyrethrum, DDT, HCH, diafuril, STOMACH POISONS are those which when ingested cause the death of the insects, e.g., paris green, ‘sodium fluoride. FUMIGANTS are those which give off vapours which have a lethal effect on the insects, e.g., sulphur dioxide. This classification is by no means a rigid one, because a contact poison can also be a stomach poison.

Most of the present-day insecticides available for vector control (excluding inorganic chemicals and tervaldial oils) may be classified conveniently into 3 groups (16):

- Group I: Organochlorine compounds: DDT, HCH, dichlor, chlordane, methoxychlor, etc.
- Group II: Organophosphorous compounds: malathion, fenitrothion, chlorpyrifos, abate, etc.
- Group III: Carbamates: Propoxur, carbaryl.

A detailed list of insecticides in public health use is given in Fig. 17. The problem of insecticide resistance and environmental contamination has restricted the use of many insecticides. A brief description of the insecticides in current use is given below:

1. DDT

DDT (Dichlorodiphenyltrichloroethane) was first synthesized in 1874, by a German chemist, Ziedler. It was in 1939, its insecticidal properties were discovered by the Swiss scientist, Paul Muller. (a) PROPERTIES: DDT is a white

![Chemical control of arthropods of public health importance](FIG. 17)
anorphous powder with a mild, but not unpleasant smell. It is insoluble in water but dissolves in most organic solvents. The technical product contains 80-85% of the para isomer, which is the most active fraction of DDT. (b) ACTION : DDT is primarily a contact poison. It acts on the nervous system of insects. It permeates into the insect body through the cuticle, after dissolving in the waxy covering of the feet, and causes paralysis of legs and wings, convulsions and finally death. DDT does not cause immediate death, but it takes several hours to kill. The residual action of DDT may last as long as 18 months, depending upon the treated surface. On mud walls, the prolonged action however, is decreased by absorption. DDT has no repellent action on insects. (c) APPLICATION : As a residual spray, DDT is applied at a dosage of 100-200 mg per square foot area. The formulation of choice is 5% suspension of DDT, which when sprayed at a rate of 1 gallon over an area of 1,000 sq. feet, gives a dosage of 200 mg per sq. ft. As a dust, DDT is used in 5 to 10 per cent strength for the control of lice, fleas, ticks and bugs. In aerial or space sprays, DDT is one of the main constituents. DDT is still one of the most widely used insecticides.

In recent years DDT has earned the reputation of being an "environmental pollutant," its persistence in the living organisms and plants and also its adverse effects on certain species of wild animals has led to the controversy on its use. Many developed countries (e.g., U.K., Sweden, Norway) have restricted the use of DDT because of its potential danger to ecosystems of wild life in the environment. But the benefits from the application of DDT in health programmes far outweigh the hazards. It has been responsible for saving millions of lives throughout the world. No toxic effects have been reported in the past 20 years among 200,000 spraymen employed in malaria campaigns nor among the 600,000 people living in repeatedly sprayed houses. A WHO Expert Committee pointed out that "there is no valid reason to discontinue the use of DDT, for application in houses, against malaria or other diseases because its safety for human use still remains unchallenged despite the tremendous amount of research." (32).

2. HCH (BHC)
Benzeno hexachloride or hexachlorocyclo-hexane or gammexane or hexadecol was synthesized much earlier than DDT by Michael Fasaday in 1825. Even its insecticidal activity was discovered before that of DDT in the USA in 1933. (a) PROPERTIES : HCH is a white or chocolate coloured powder with a musty smell. It is irritating to the eyes, nose and skin. In its crude form, it is composed of a number of isomers of which the gamma isomer is the most active constituent. The technical HCH contains 13 to 16 per cent of the gamma isomer. Pure HCH containing 99 per cent of the gamma isomer is called Indane or gamma HCH. Indane is slightly volatile. It is more insecticidal than DDT, although its insecticidal action is not as prolonged as that of DDT. (b) ACTION : HCH kills insects by direct contact, but its residual action is of a shorter duration, up to 3 months or so as compared with the longer residual action of DDT. HCH kills insects by its vapour effect also. (c) APPLICATION : HCH is used like DDT. A dose of 25 to 50 mg of gamma- HCH per sq. ft. is recommended for residual treatment.

3. Malathion
Malathion has the least toxicity of all organophosphorous compounds. The technical product is a yellow or clear brown liquid with an unpleasant smell. Commercially, water-dispersible powders are available. Malathion is used in doses of 100-200 mg per sq. ft., every 3 months. Because of its low toxicity, malathion has been recommended as an alternative insecticide to DDT. As a low volume (ULV) spray, malathion has been widely used for killing adult mosquitoes to prevent or interrupt dengue–haemorrhagic fever, and mosquito-borne encephalitis epidemics (9).

4. Abate
Abate (Temephos) is an organophosphorous compound. It is a brown viscous liquid, soluble in petroleum solvents. Because of its low toxicity, it has been extensively used in India for the control of A. stephensi in wells and in domestic water containers with good results at a dosage not greater than 1.0 ppm. Abate is less effective as adulticide (9).

5. Diazinon
Diazinon is a liquid product. Being volatile, it kills insects not only by direct contact, but also by fumigant action. It has proved effective in the control of DDT-resistant insects. At a dosage of 60 to 100 mg per sq. foot, it has given satisfactory control of fleas and mosquitoes. Diazinon is more toxic to man than malathion or fenithion.

6. Fenthion
Fenthion or butaxes is a brown liquid smelling slightly of garlic. It is practically insoluble in water. Water dispersible powders are available containing 20 to 40 per cent fenithion. Fenthion is found to be as effective as DDT. The usual dosage for residual sprays is 100 mg/sec ft. As a larvicidal, fenithion is reported to be very powerful. Granules and dust formulations have been used in anti-larval work. The WHO Filaria Research Unit in Banga found fenithion, applied at the rate of 1 ppm, highly effective in controlling the larvae of C. falciparum.

7. Dichlorvos or DDVP
Dichlorvos or DDVP is highly volatile liquid insecticide, which kills insects by fumigant action. It has been successfully used for disinfecting aircraft. A special advantage of DDVP is that it can be combined with solid substances such as wax, which can be fashioned into tablets or bricks from which it slowly evaporates.

8. Propoxur
The new carbamate insecticide, propoxur has been recommended as a substitute for DDT in areas where the anophelines have developed resistance to both DDT and dieldrin.

9. Pyrethrum
Pyrethrum is an insecticide of vegetable origin. It is extracted from the flowers of Chrysanthemum cinerarifolium, a plant which is cultivated in Kashmir, Simla and Nilgiris in India. The flowers contain 4 active principles : Pyrethrins I and II, cinerins I and II — all nerve poisons. Pyrethrum extract is prepared by soaking 1/2 to 1 lb of dried, powdered flowers in 1 gallon of kerosene oil for 72 hours, when the active principles are extracted. The ready-to-spray solution contains up to 0.1 per cent of pyrethrum. Pyrethrum extract is an excellent space spray. It has been used extensively in the past for killing adult mosquitoes, and other insects. It kills instantly on mere contact. It is sprayed at the rate of 1/2 to 1 oz. of the spray solution per 1,000 sq. ft. of space. As a space spray, fine atomization of the spray solution is necessary and the doors and windows should be
kept closed for 1/2 hour after spraying. Pyrethrum suffers from the disadvantage that it does not possess the residual action of DDT and other synthetic insecticides.

10 Pyrethrin and DDT

Most space sprays contain pyrethrum and DDT or other synthetic insecticides, which are added for synergistic action. The standard reference aerosols recommended by the WHO consists of (a) pyrethrum extract (25% pyrethrins) - 1.6 per cent, and (b) DDT technical - 3 per cent to be dispersed at the rate of 10 g. per 1,000 cu. ft. of space in the treatment of aircraft. About one-third of the WHO's 5,333 per 1,000 cu. ft. may be used for routine treatment of dwellings.

11. Synthetic pyrethroids

Synthetic pyrethroids are now being developed to replace natural pyrethrins. Some of the newly developed synthetic pyrethroids have been found to be as much as 10 times as effective as naturally occurring pyrethrins. Among the synthetic pyrethroids developed so far, tetramethrin, resmethrin, propethrin and propoxur seem to be the most promising ones (39).

12. Rotenone

Rotenone is obtained from the roots of a plant, Derris elliptica. The roots are dried and powdered and then are blended to give a rotenone content between 4 to 5 per cent and used as insecticidal dust. An extract of rotenone may be made in organic solvents such as chloroform. Rotenone was once widely used in the control of lice, fleas, mites and ticks.

13. Mineral oils

Gason, so-called kerosene, crude oil, mineral oil have been extensively used to kill mosquito larvae and pupae. Oils suffocate and poison the aquatic stages of the mosquito. The killing power of oil is increased greatly by the addition of DDT, HCH and other chemicals. Oils are injurious to vegetation and fish when improperly used.

14. Paris green

Paris green, copper aceto-arsenite is an emerald green microcrystalline powder, practically insoluble in water but soluble in ammonia and concentrated acids. A good sample of paris green contains over 50 per cent of arsenious oxide. Paris green is a stomach poison. Till the advent of DDT, paris green was extensively used in the control of anopheline larvae, by spraying as a 2 per cent dust over breeding places once a week. The use of paris green was largely responsible for the eradication of A. gambiense from Brazil in 1940, and the near-eradication of the same species in Egypt in 1944.

INSECTICIDE RESISTANCE

The widespread use of synthetic insecticides has given rise to the serious problem of insecticide resistance practically all over the world. The magnitude of the problem can be appreciated from the fact that, whereas in 1946 resistance to insecticides was reported in only 2 species of insects of public health importance, in 1962, the number rose to 81 species and in 1980 to 134. Evidence has accumulated to show that resistance in many vectors has been caused as a side effect of agricultural pesticide usage.

Resistance has been defined by VRIO (1957) as "the development of an ability in strain of insects to tolerate doses of toxicants which would prove lethal to the majority of individuals in normal population of the same species" (34). Resistance is due to biochemical and genetic factors. In the former, the toxicant is converted into a non-toxicant form in the body of the insect by various enzymes. In the latter, resistance is transmitted through genes, single or multiple.

A knowledge of insecticide resistance is important from the point of view of proper selection of insecticides. Organochlorine insecticides are divided into two groups: resistance to DDT and its analogues, and the other to HCH-dieldrin group of insecticides. Resistance to DDT amounts to resistance to a number of DDT analogues such as methoxychlor, but not to HCH-dieldrin group. Similarly resistance to HCH amounts to resistance to Dieldrin, but not to DDT. Many insects now have developed "double resistance", that is, resistance to the two groups of organochlorine insecticides. When an insect develops resistance to DDT and HCH, the only effective action that can be taken is to change over to organophosphorus and carbamate insecticides. The change to organophosphorus and carbamate compounds involves substantial increase in cost, as these are all costly insecticides. Furthermore, cases of resistance towards them have already appeared. There is cross resistance between most carbamates and most organophosphorus compounds. To sum up, the problem of insecticide resistance which is growing in magnitude, is no doubt, steadily diminishing the choice of effective insecticides for vector control.

TOXICITY OF INSECTICIDES

1. Organochlorine compounds

DDT and its chemical relations are all nerve poisons. They increase the nervous excitability, and cause tremor and convulsions. Some of the chlorinated hydrocarbon compounds namely DDT, HCH and dieldrin, DDT's the least toxic. The median lethal dose for the humans is about 250 mg per kg. of body weight. Gamma-HCH is about twice as toxic as DDT, and dieldrin is about 5 to 8 times as toxic as DDT. Dieldrin poisoning is met with more frequently than DDT or PCH poisoning. The oil is absorbed through the skin whereas DDT and PCH are not absorbed through the skin in the solid state. TREATMENT: Poisoning with chlorinated hydrocarbon compounds is treated with barbiturates specifically phenobarbitone. Stomach washouts are generally necessary, purgative may be useful but no oils or fats should be given.

2. Organophosphorus compounds and carbamates

These insecticides interfere with the mechanism of transmission of nerve impulses. They act by inhibiting cholinesterase, the enzyme which catalyses the dephosphorylation of acetyl choline in the synapse of striated muscle. Consequently there is accumulation of acetyl choline. The effects of poisoning are headache, giddiness, apprehension, restlessness, cold sweating, salivation, uncontrolled urination and defecation, unconsciousness and in extreme cases, ataxia and paralysis of respiratory centre. TREATMENT: Atropine is the specific antidote for poisoning by organophosphorus insecticides. It should be injected in doses of 1 to 2 mg intramuscularly and repeated if necessary at 30 minutes interval. Three very specific drugs are available at present - 2 PAM iodine, 2 PAM chloride, and 925 (35). Atropine should be combined with one of these compounds. It is necessary that drugs be supplemented by other measures such as removal of the contaminated clothes, and washing of the exposed skin with soaps and water.

Cases of poisoning due to organophosphorus compounds are on the increase in India. Those who are called upon to
render First Aid and/or treat cases of pesticide poisoning would do well to refer to "Instructions for Safe use of Pesticides" issued by the Plant Protection Advisor to Government of India, Faridabad, Haryana wherein specific antidotes for groups of pesticides are given. The passing of "Indian Insecticide Act" by Parliament with a view regulating the manufacture, transport, distribution, sale and use of pesticides is a step in the right direction.

A summary of treatment of poisoning with insecticides may be found in the WHO Publication "Safe Use of Pesticides" Technical Report Series No. 513 on page 52.

**RODENTS**

Rats and mice are part of man's environment. Often their numbers exceed human population. A female rat can have 100 offspring each year. By living in close proximity to man, they not only cause substantial economic loss by damaging buildings, consuming and contaminating foodstuffs (30/6) and other commodities, but also act as reservoir or reservoirs of some important communicable diseases such as plague and typhus fever. It implies therefore, that destruction of rats and elimination of their habitat is an important environmental health measure.

Rodents may be classified into two distinct groups: domestic and wild. (1) DOMESTIC RODENTS: The rodents of chief public health concern are those that live in close association with man, namely the black rat (Rattus rattus) and the Norway rat (R. norvegicus) and the house mouse (Mus musculus). Rattus rattus is a domestic animal whose area of movement is usually restricted. It readily enters ships, and therefore its public health importance is considerable. Rattus rattus is also a good climber and infestation generally occurs in the roofs of houses, though in some places it does burrow. R. norvegicus, on the other hand is a semi-domestic animal which frequents sewers, drains as well as houses. Characteristics which are easily distinguishable of R. rattus and R. norvegicus are illustrated in Fig. 1.

(2) WILD RODENTS: The common wild rodents in India are Tatera indica, Bandicota bengalensis varius (Gunyamys kori), B.indica, Millodon melodio, M. gladouisi and Mus booduga. In India, Tatera indica has been found to be the natural reservoir of plague.

**Rodents and disease (36)**

A number of diseases are associated with rodents. Broadly these are: (1) Bacterial: plague, tularemia, salmonellosis; (2) Viral: Lassa fever, haemorrhagic fever, encephalitis; (3) Rickettsial: scrub typhus, murine typhus, rickettsial pox; (4) Parasitic: yemenolepsis diminuta, leishmaniasis, amoebiasis, trichinosis, Chagas disease; and (5) Others: rat bite fever, leptospirosis, histoplasmosis, ring worm etc.

The mode of transmission may be directly through rat bite (e.g., rat bite fever); some through contamination of food or water (e.g., salmonellosis, leptospirosis) and some through rat fleas (e.g., plague and typhus).

**Antirodent measures**

1. Sanitation measures: Sound environmental sanitation is the most effective weapon in deratization campaign. Rats require three things: food, water and shelter. If these are denied, rats will naturally decrease in density. The environmental sanitation measures comprise: (1) proper storage, collection and disposal of garbage, (2) proper storage of food-stuff, (3) construction of rat-proof buildings, godowns and warehouses, and (4) elimination of rat burrows by blocking them with concrete. Sanitation is therefore essential to the permanent control of rats and mice, and all measures should be regarded as supplementary to sanitation.

2. Trapping: Trapping of rats is a simple operation, but it causes temporary reduction in the number of commercial rodents. It is recommended that the number of traps laid should be at least 5 per cent of the human population. The 'wonder trap' developed by the Hoffline Institute, Mumbai is credited to trap as many as 25 rats at a time. The traps are

usually baited with indigenous foods of the locality. The captured rats must be destroyed which may be done by drowning them in water. Rats by nature are suspicious animals, and will soon become "trap-wise" and avoid baited traps. Trapping therefore should be considered supplementary to other methods of rodent control.

3. Rodenticides: Rodenticides are of two main types - single-dose (acute) and multiple-dose (cumulative). The former are lethal to the rat after a single feeding, while the latter require repeated feedings over a period of 3 more days (17).

An Expert Committee of the WHO (37) grouped the "acute" rodenticides as below:

1. Those requiring ordinary care
   Red squill
   Norbromide
   Zinc phosphide

2. Those requiring maximal precaution
   Sodium fluoroacetate
   Fluoroacetamide
   Strychnine

3. Too dangerous for use
   Arsenic trioxide
   Phosphorus
   Thallium sulphate
   ANTU
   Gophicide.

The commonly used poisons in this country are:
(i) Barium carbonate: This is a white tasteless powder, and is very cheap. It is mixed with wheat or rice flour in the ratio of 1 part to 4 parts of flour. The mixed material is moistened with water and made into small round marbles. The poisoned baits are placed near the rat burrows and in dark, secluded places. On eating the pills, rats are killed in 2 to 24 hours. Barium carbonate is a weak rodenticide of uneven performance, and probably easily detected by rats in many baits. In the opinion of many workers, in view of the availability of more efficient rodenticides, barium carbonate should not be used any more (38).
(ii) Zinc phosphide: Zinc phosphide is an efficient rodenticide. When moist, the chemical slowly gives off phosphine whose garlic odour is repellant to man and domestic animals, but seems to have no adverse effect on rats. Zinc phosphide is now extensively used in India. It is used in the ratio of 1 part to 10 parts of wheat or rice flour and mixed with a few drops of edible oil in order to render it more attractive to rats. Rats are killed in about three hours. The use of rubber gloves is recommended in handling zinc phosphide as it is highly poisonous. Special bait boxes have been designed for the administration of very toxic compounds such as zinc phosphide to eliminate the risk to man and domestic animals. Because of its good safety record, low cost and reasonably high attractiveness, Zinc phosphide is recommended for large scale use against rats (38).

The multiple-dose (cumulative) poisons are: warfarin, diphacinone, coumatryptol and pindone (17). As anticoagulants, they cause internal haemorrhage and slow death in 4 to 10 days. The continued use of anticoagulant rodenticides has led to the appearance of resistant Norwegian rat populations in several European countries. In some countries, the use of chronic rodenticides has been given up. All rodent poisons are toxic to mammals including man and call for the utmost care in their use.

(4) Fumigation: Fumigation is an effective method of destroying, both rats and rat fleas. The fumigants used in anti-rat campaigns are calcium cyanide (often called cyanoagas or cyanag), carbon disulphide, methods of a number of diseases. The WHO records more than 150 diseases and infections of animals communicable to man (40) - these are termed "infectious diseases" by WHO. The WHO Expert Committee (1967) defined zoonoses as "those diseases and infections which are naturally transmitted between vertebrate animals and man."

Zoonotic diseases may be due to viruses, bacteria, rickettsiae, fungi, helminths, protozoa, arthropods or insects. The WHO (1967) classified zoonoses into different groups (40). Some of the important zoonoses are as given in Table 1.

India has the largest animal population in the world which is nearly 11 per cent of the total world animal population. Being an agricultural country the relationship between man and animals is the closest in this country. It is not uncommon to see animals and human beings living under the same roof. The available information indicates that a large number of zoonotic infections (e.g., brucellosis, rashes, tuberculosis, leptospirosis, typhus fever) occur in different parts of the country. Except for rabies, the prevalence of other diseases in human being is not well mapped out. The National Institute of Communicable Diseases, Delhi is making efforts to organize systematic and collaborative studies with other Institutions on different zoonotic infections. The WHO has a section of Veterinary Public Health in its Division of Communicable Diseases. The control of zoonoses is a challenge facing the veterinary public health today.

### Control of zoonoses

The principal components of control are: (a) Control in animals: The measure comprises diagnosis of the zoonotic condition, treatment, destruction, quarantine and immunization. (b) Control of vehicles of transmission: These include establishment of food hygiene practices, ensuring safety of animal products such as wool, hides, horn, bones, fat, etc.; proper disposal of animal carcasses and wastes, and disinfection procedures. (c) Prevention and treatment in man: This involves protection of high risk groups, by immunization, chemotherapy, monitoring of health status including occupational health programmes, prevention of spread by man, early diagnosis and treatment of the condition in man, health education, prevention of environmental contamination, prevention of food contamination, and improvement of diagnostic facilities (42).

During the past 50 years, the concept of environment has become broad-based. Modern ecologists use the term in its widest sense. The concept of environment covers first the general environment, for instance water and air pollution, to which an individual is exposed. Secondly, it refers to the personal environment created by the individual himself—including such cultural habits as cigarette smoking, alcohol, drug addiction. This has been described as "chemical environment". The concept that the general everyday chemical environment could also be dangerous to human health is not always. Environment is accumulating that environmental factors, especially factors in the chemical environment, play a major role in carcinogenesis, and that many cancer by is theoretically preventable (42).

It is now current jargon to advocate an "integrated" approach to the environmental problems where all aspects of a given problem are looked at from all angles. It implies an unprecedented cooperation between different services and disciplines. The United Nations Environmental Programme (UNEP), UNESCO's Man and Biosphere (MAB) Programme, WHO's Environmental Health Criteria Programme, and the UN's International Drinking Water Supply and Sanitation Decade 1981-1990 are efforts in the direction to promote health in the human environment.

### References
Let the wastes of "the sick" not contaminate the lives of "the healthy"

The waste produced in the course of health-care activities carries a higher potential for infection and injury than any other type of waste. Therefore, it is essential to have safe and reliable method for its handling. Inadequate and inappropriate handling of health-care waste may have serious public health consequences and a significant impact on the environment. Appropriate management of health-care waste is thus a crucial component of environmental health protection, and it should become an integral feature of health-care services.

**Definition**

According to Bio-Medical Waste (Management and Handling) Rules, 1998 of India, "Bio-medical waste" means any waste, which is generated during the diagnosis, treatment or immunization of human-beings or animals, or in research activities pertaining thereto or in the production or testing of biologicals, and including categories as mentioned in schedule I in Table 4 (2).

Between 75 to 90 per cent of the waste produced by the health-care providers is non-risk or "general" health-care waste, comparable to domestic waste. It comes mostly from administrative and house keeping functions of the health-care establishments, and may also include waste generated during maintenance of health-care premises. The remaining 10–25 per cent health-care waste is regarded as hazardous and may create a variety of health risk (2). The classification of health-care waste is summarised in Table 1.

**Sources of health-care waste**

The institutions involved in generation of bio-medical waste are:

- Government hospitals.
- Private hospitals.
- Nursing homes.
- Physician's office/clinics.
- Dentist's office/clinics.
- Dispensaries.
- Primary health centres.
- Medical research and training establishments.
- Mortuaries.
- Blood banks and collection centres.
- Animal houses.
- Slaughter houses.
- Laboratories.
- Research organizations.
- Vaccinating centres, and
- Bio-technology institutions/production units.

All these health-care establishments generate waste and are therefore, covered under Bio-Medical Waste (BMW) Rules (1).

**Health-care waste generation**

Several surveys have provided an indication of typical health-care waste generation, and it shows that this differs not only from country to country but also within the country. Waste generation depends on numerous factors such as established waste management methods, type of health-care establishment, hospital specializations, proportion of reusable items employed in health-care, and proportion of patients treated on a day-care basis.

In middle and low income countries, health-care waste generated is lower than in high-income countries. Developing countries that have not performed their own

Classification of health-care waste
surveys of health-care waste, find the following estimates for an average distribution of health-care wastes useful for preliminary planning of waste management (2):
- 80 per cent general health-care waste, which may be dealt with by the normal domestic, and urban waste management system;
- 10 per cent pathological and infectious waste;
- 1 per cent sharps waste;
- 3 per cent chemical and pharmacological waste;
- Less than 1 per cent special waste, such as radio-active or cytotoxic waste, pressurized containers, or broken thermometers and used batteries.

Table 2 shows average composition of waste obtained from 10 large hospitals in Mumbai, Kolkata, Delhi, and Nagpur during the period 1993-1996.

Source: (National Environmental Engineering Research Institute 1997)

A survey done in Bangalore revealed that the quantity of solid wastes generated in hospitals and nursing homes generally varies from 1/2 to 4 kg per bed per day in Govt. hospitals, 1/2 to 2 kg per bed per day in private hospitals, and 1/2 to 1 kg per bed per day in nursing homes. The total quantity of hospital wastes generated in Bangalore is about 40 tonnes per day. Out of these nearly 45 to 50 per cent is infectious. Segregation of infectious wastes from non-infectious wastes is done only in about 30 per cent of hospital (3).

Health hazards of health-care waste

Exposure to hazardous health-care waste can result in disease or injury due to one or more of the following characteristics:
- It contains infectious agents;
- It contains toxic or hazardous chemicals or pharmaceuticals;
- It contains sharps;
- It is genotoxic; and
- It is radio-active.

All individuals exposed to such hazardous health-care waste are potentially at risk, including those who generate the waste or those who either handle such waste or are exposed to it as a consequence of careless management. The main groups at risk are:
- Medical doctors, nurses, health-care auxiliaries, and hospital maintenance personnel;
- Patients in health-care establishments;
- Visitors to health-care establishments;
- Workers in support service allied to health-care establishments such as laundries, waste handling and transportation; and
- Workers in waste disposal facilities such as land-fills or incinerators including scavengers.

1. Hazards from infectious waste and sharps

Pathogens in infectious waste may enter the human body through a puncture, abrasion or cut in the skin, through mucous membranes by inhalation or by ingestion. There is particular concern about infection with HIV and hepatitis virus B and C, for which there is a strong evidence of transmission through health-care waste. Bacteria resistant to antibiotics and chemical disinfectants, may also contribute to the hazards created by poorly managed waste.

2. Hazards from chemical and pharmaceutical waste

Many of the chemicals and pharmaceuticals used in health-care establishments are toxic, genotoxic, corrosive, flammable, reactive, explosive or shock-sensitive. Although present in small quantity they may cause intoxication, either by acute or chronic exposure, and injuries, including burns. Disinfectants are particularly important members of this group. They are used in large quantities and are often corrosive, reactive chemicals may form highly toxic secondary compounds.

3. Hazards from genotoxic waste

The severity of the hazards for health-care worker responsible for handling or disposal of genotoxic waste is governed by a combination of the substance toxicity itself and the extent and duration of exposure. Exposure may also occur during the preparation or treatment with particular drug or chemical. The main pathway of exposure is inhalation of dust or aerosols, absorption through the skin, ingestion of food accidentally contaminated with cytotoxic drugs, chemicals or waste etc.

4. Hazards from radio-active waste

The type of disease caused by radio-active waste is determined by the type and extent of exposure. It can range from headache, dizziness and vomiting to much more serious problems. Because it is genotoxic, it may also affect genetic material.

5. Public sensitivity

Apart from health hazards, the general public is very sensitive to visual impact of health-care waste particularly anatomical waste.

Treatment and disposal technologies for health-care waste

Incineration, used to be the method of choice for most hazardous health-care wastes, and is still widely used. However, recently developed alternative treatment methods are becoming increasingly popular. The final choice of treatment should be made on the basis of factors, many of which depend on local conditions.

I. Incineration

Incineration is a high temperature dry oxidation process, that reduces organic and combustible waste to inorganic incinerable matter and results in a very significant reduction of waste-volume and weight. The process is usually selected to treat wastes that cannot be recycled, reused or disposed off in a land fill site.

The flow diagram of incinerator is as shown in Fig. 1.
Incineration requires no pre-treatment, provided that certain waste types are not included in the matter to be incinerated. Characteristics of the waste suitable for incineration are: (a) low heating value - above 2,000 kcal/kg for single-chamber incinerators, and above 3,500 kcal/kg for pyrolytic double-chamber incinerators; (b) content of combustible matter above 60 per cent; (c) content of non-combustible solids below 5 per cent; (d) content of non-combustible lines below 20 per cent; and (e) moisture content below 30 per cent [2].

Waste types not to be incinerated are: (a) pressurized gas containers; (b) large amount of reactive chemical wastes; (c) silver salts and photographic or radiographic wastes; (d) Halogenated plastics such as PVC; (e) waste with high mercury or cadmium content, such as broken thermometers, used batteries, and lead-lined wooden panels; and (f) sealed ampules or ampules containing heavy metals [2].

**TYPES OF INCINERATORS**

Incinerators can range from very basic combustion units that operate at much lower temperature to extremely sophisticated, high temperature operating plants. It should be carefully chosen on the basis of the available resources, the local situation, and the risk-benefit consideration.

Three basic kinds of incineration technology are of interest for treating health-care waste: (a) Double-chamber pyrolytic incinerators which may be especially designed to burn infectious health-care waste; (b) Single-chamber furnaces with static grate, which should be used only if pyrolytic incinerators are not affordable; and (c) Rotary kilns operating at high temperatures, capable of causing decomposition of genotoxic substances and heat-resistant chemicals.

**II. Chemical disinfection**

Chemicals are added to waste to kill or inactivate the pathogens it contains, this treatment usually results in disinfection rather than sterilization. Chemical disinfection is most suitable for treating liquid waste such as blood, urine, stools or hospital sewage. However, solid wastes including microbiological cultures, sharps etc. may also be disinfected chemically with certain limitations.

**III. Wet and dry thermal treatment**

WET THERMAL TREATMENT: Wet thermal treatment or steam disinfection is based on the exposure of shredded infectious waste to high temperature, high pressure steam, and is similar to the autoclave sterilization process. The process is inappropiate for the treatment of anatomical waste and animal carcasses, and will not efficiently treat chemical and pharmaceutical waste.

SCREW-FEED TECHNOLOGY: Screw-feed technology is the basis of a non-burn, dry thermal disinfection process in which waste is shredded and heated in a rotating auger. The waste is reduced by 80 per cent in volume and by 20–35 per cent in weight. This process is suitable for treating infectious waste and sharps, but it should not be used to process pathological, cytotoxic or radio-active waste.

**IV. Microwave irradiation**

Most microorganisms are destroyed by the action of
microwave of a frequency of about 2450 MHz and a wave length of 12.24 µm. The water contained within the waste is rapidly heated by the microwaves and the infectious components are destroyed by heat conduction. The efficiency of the microwave disinfection should be checked routinely through bacteriological and virological tests.

V. Land disposal

MUNICIPAL DISPOSAL SITES: If a municipality or medical authority genuinely lacks the means to treat waste before disposal, the use of a landfill has to be regarded as an acceptable disposal route. There are two types of disposal land–open dumps and sanitary landfills. Health-care waste should not be deposited on or around open dumps. The risk of either people or animals coming into contact with infectious pathogens is obvious. Sanitary landfills are designed to have at least four advantages over open dumps: geological isolation of waste from the environment, appropriate engineering preparation before the site is ready to accept waste, staff present on site to control operations, and organized deposit and daily coverage of waste.

VI. Inertization

The process of "inertization" involves mixing waste with cement and other substances before disposal, in order to minimize the risk of toxic substances contained in the wastes migrating into the surface water or ground water. A typical proportion of the mixture is: 65 per cent pharmaceutical waste, 15 per cent lime, 15 per cent cement and 5 per cent water. A homogeneous mass is formed and cubes or pellets are produced on site and then transported to suitable storage sites.

The main advantages and disadvantages of various treatment and disposal options are listed in Table 3.

NATIONAL legislation is the basis for improving health-care waste disposal practices in any country. It establishes legal

Source: (2)
control, and permits the national agency responsible for the disposal of health-care waste, usually the Ministry of Health, to apply pressure for their implementation. The Ministry of Environment may also be involved. There should be a clear designation of responsibilities before the law is enacted.

The United Nations Conference on the Environment and Development (UNCED) in 1992 recommended the following measures:

(a) Prevent and minimize waste production
(b) Recycle or re-use the waste to the extent possible
(c) Treat waste by safe and environmentally sound methods, and
(d) Dispose of the final residue by landfill in confined and carefully designed sites.

Bio-Medical Waste Management in India (1, 4, 5)

The bio-medical waste should be segregated into containers/bags at the point of generation of the waste. The colour coding and the type of containers used for disposal of waste are as shown in Table 5. Fig. 2 shows the label for bio-hazards symbol and cytotoxic hazard symbol which should be prominently visible and non-washable.

**References**

A "disaster" can be defined as "any occurrence that causes damage, ecological disruption, loss of human life or deterioration of health and health services on a scale sufficient to warrant an extraordinary response from outside the affected community or area" (1).

A "hazard" can be defined as any phenomenon that has the potential to cause disruption or damage to people and their environment (2).

Emergencies and disasters do not only affect health and well-being of people; frequently, large number of people are displaced, killed or injured, or subjected to greater risk of epidemics. Considerable economic harm is also common. Disasters cause great harm to the existing infrastructure and threaten the future of sustainable development.

Disasters are not confined to a particular part of the world; they can occur anywhere and at any time. Major emergencies and disasters have occurred throughout history and as the world's population grows and resources become more limited, communities are increasingly becoming vulnerable to the hazards that cause disasters. Statistics gathered since 1969 show a rise in the number of people affected by disasters. Since there is little evidence that the actual events causing disasters are increasing in either intensity or frequency, it can only be concluded that vulnerability to disaster is growing. For each disaster listed in officially recognized disaster database, there are some 20 other smaller emergencies with destructive impact on local communities that go unacknowledged.

There are many types of disasters such as earthquakes, cyclones, floods, tidal waves, land-slides, volcanic eruptions, tornadoes, fires, hurricanes, snow storms, severe air pollution (smog), heat waves, famines, epidemics, building collapse, toxicologic accidents (e.g., release of hazardous substances), nuclear accidents and warfare etc. Warfare is a special category, because damage is the intended goal of action. Every catastrophic event has its own special features. Some can be predicted several hours or days before-hand, as in the case of cyclones or floods, others such as earthquakes occur without warning.

The relative number of injuries and deaths differ, depending on a number of factors such as the type of disaster, the density and distribution of the population, condition of the environment, degree of the preparedness and opportunity of the warning. Injuries usually exceed death in explosions, earthquakes, typhoons, hurricanes, fires, tornadoes etc. Death frequently exceeds injuries in landslides, avalanches, volcanic eruptions, tidal waves, floods etc. (3).

The types of emergency vary according to the kind of disaster, and how and when it strikes. In earthquakes, there is a high level of mortality, as a result of people being crushed by falling objects. The risk is greater inside or near dwellings but is very small in the open. Consequently earthquakes at night are more deadly. During the night, fractures of pelvis, thorax and spine are common, because earthquake strikes while people are lying in bed. In daytime injuries to the arms and skull are common. In volcanic eruptions, mortality is high in the case of mudslides (e.g., 23,000 deaths in Colombia in 1985) and glowing clouds (e.g., 30,000 deaths at Saint Pierre in Martinique). There may be injuries, burns and suffocation. In floods, mortality is high only in case of sudden flooding e.g., flash floods, collapse of dams or tidal waves. Fractures, Injuries and bruises may occur. If weather is cold, cases of accidental hypothermia may occur. In cyclones and hurricanes, mortality is not high unless tidal waves occur. The combined, effect of wind and rain may cause houses to collapse. A large number of objects may be lifted in the air and carried along by the wind. This may give rise to injuries. In droughts, mortality may increase considerably in areas where drought cause famines, in which case there may be protein-calorie malnutrition and vitamin deficiencies particularly vitamin A deficiency, leading to xerophthalmia and blindness. In famine conditions, measles, respiratory infections, diarrhoea accompanied by dehydration may bring about a massive increase in infant mortality. When people migrate and settle down on the outskirts of famine hit areas, poor hygiene and overcrowding may facilitate the spread of endemic communicable diseases e.g., tuberculosis, parasitic diseases and malaria (4).

On the whole, morbidity which results from a disaster situation can be classified into four types:

a. Injuries,

b. Emotional stress;

c. Epidemic of disease; and

d. Increase in indigenous diseases.

The short-term effects of major disasters are summarised in Table 1.

**DISASTER MANAGEMENT**

There are three fundamental aspects of disaster management:

a. disaster response;

b. disaster preparedness; and
c. disaster mitigation.

These three aspects of disaster management correspond to different phases in the so-called "disaster cycle" as shown in Fig. 1.

**Risk reduction phase before a disaster**

Preparedness

Disaster Impacts

Response

Mitigation

Recovery phase after a disaster

Reconstruction

Rehabilitation

**Disaster impact and response**

Medical treatment for large number of casualties is likely to be needed only after certain types of disaster. Most injuries are sustained during the impact, and thus, the greatest need for emergency care occurs in the first few hours. The management of mass casualties can be further divided into search and rescue, first aid, triage and stabilization of victims, hospital treatment and redistribution of patients to other hospitals if necessary.

Search, rescue and first aid

After a major disaster, the need for search, rescue and first aid is likely to be so great that organized relief services will be able to meet only a small fraction of the demand. Most immediate help comes from the uninjured survivors.

**Field care**

Most injured persons converge spontaneously to health facilities, using whatever transport is available, regardless of the facilities, operating status. Providing proper care to casualties requires, that the health service resources be redirected to this new priority. Bed availability and surgical services should be maximized. Provisions should be made for food and shelter. A centre should be established to respond to inquiries from patients' relatives and friends. Priority should be given to victims' identification and adequate mortuary space should be provided.

**Triage (5)**

When the quantity and severity of injuries overwhelm the operative capacity of health facilities, a different approach to medical treatment must be adopted. The principle of "first come, first treated", is not followed in mass emergencies. Triage consists of rapidly classifying the injured on the basis of the severity of their injuries and the likelihood of their survival with prompt medical intervention. It must be adopted to locally available skills. Higher priority is granted to victims whose immediate or long term prognosis can be dramatically affected by simple intensive care. Mortally patients who require a great deal of attention with questionable benefit, have the lowest priority. Triage is the only approach that can provide maximum benefit to the greatest number of injured in a major disaster situation.

Although different triage systems have been adopted and are still in use in some countries, the most common classification uses the International accepted four colour code system. Red indicates high priority treatment or transfer, yellow signals medium priority, green indicates ambulatory patients and black for dead or moribund patients.

Triage should be carried out at the site of disaster, in order to determine transportation priority, and admission to the hospital or treatment centre, where the patient's needs and priority of medical care will be reassessed. Ideally, local health workers should be taught the principles of triage as part of disaster training.

Persons with minor or moderate injuries should be treated at their own homes to avoid social dislocation and
the added drain on resources of transporting them to central facilities. The seriously injured should be transported to hospitals with specialised treatment facilities.

**Tagging**

All patients should be identified with tags stating their name, age, place of origin, triage category, diagnosis, and initial treatment.

**Identification of dead**

Taking care of the dead is an essential part of the disaster management plan. The dead should be transported promptly. Care of the dead includes: (1) removal of the dead from the disaster site; (2) disposal of the body; (3) identification; (4) reception of bereaved relatives. Proper respect for the dead is of great importance.

The health hazards associated with cadavers are minimal if death results from trauma, and corpses are quite unlikely to cause outbreaks of disease such as typhoid fever, cholera or plague. If human bodies contaminate streams, wells, or other water sources as in floods etc., they may transmit gastroenteritis or food poisoning to survivors. The dead bodies represent a delicate social problem.

**Relief phase**

This phase begins when assistance from outside starts to reach the disaster area. The type and quantity of humanitarian relief supplies are usually determined by two main factors: (1) the type of disaster, since distinct events have different effects on the population, and (2) the type and quantity of supplies available locally.

Immediately following a disaster, the most critical health supplies are those needed for treating casualties, and preventing the spread of communicable diseases. Following the initial emergency phase, needed supplies will include food, blankets, clothing, shelter, sanitation, engineering equipment and construction materials. A rapid damage assessment must be carried out in order to identify needs and resources. The duration of relief should be calculated to receive large quantities of donations. There are four principal components in managing humanitarian supplies: (a) acquisition of supplies; (b) transportation; (c) storage; and (d) distribution.

**Epidemiologic surveillance and disease control**

Disasters can increase the transmission of communicable diseases through following mechanisms:

1. Overcrowding and poor sanitation in temporary resettlements. This accounts in part, for the reported increase in acute respiratory infections etc. following the disasters.

2. Population displacement may lead to introduction of communicable diseases to which either the migrant or indigenous populations are susceptible.

3. Disruption and the contamination of water supply, damage to sewerage system and power systems are common in natural disasters.

4. Disruption of routine control programmes as funds and personnel are usually diverted to relief work.

5. Ecological changes may favour breeding of vectors and increase the vector population density.

6. Displacement of domestic and wild animals, who carry with them zoonoses that can be transmitted to humans as well as to other animals. Leptospirosis cases have been reported following large floods (as in Orissa, India, after super cyclone in 1999). Anthrax has been reported occasionally.

**Outbreak of gastroenteritis**

Outbreak of gastroenteritis, which is the most commonly reported disease in the post-disaster period, is closely related to first three factors mentioned above. Increased incidence of acute respiratory infections is also common in displaced population. Vector-borne diseases will not appear immediately, but may take several weeks to reach epidemic levels.

Displacement of domesticated and wild animals increases the risk of transmission of zoonoses. Veterinary services may be needed to evaluate such health risks. Dogs, cats and other domestic animals are taken by their owners to or near temporary shelters. Some of these animals may be reservoirs of infections such as leptospirosis, rickettsiosis etc. Wild animals are reservoirs of infections which can be fatal to man such as equine encephalitis, rabies, and infections still unknown in humans.

The principals of preventing and controlling communicable diseases after a disaster are to (a) implement as soon as possible all public health measures, to reduce the risk of disease transmission; (b) organise a reliable disease reporting system to identify outbreaks and to promptly initiate control measures; and (c) investigate all reports of disease outbreaks rapidly (5).

**Vaccination**

Health authorities are often under considerable public and political pressure to begin mass vaccination programmes, usually against typhoid, cholera and tetanus. The pressure may be increased by the press media and offer of vaccines from abroad.

The WHO does not recommend typhoid and cholera vaccines in routine use in endemic areas. The newer typhoid and cholera vaccines have increased efficiency, but because they are multidose vaccines, compliance is likely to be poor. They have not yet been proven effective, as a large-scale public health measure. Vaccination programme requires large number of workers who could be better employed elsewhere. Supervision of sterilization and reinsertion techniques may be impossible, resulting in more harm than good. And above all, mass vaccination may lead to false sense of security about the risk of the disease and to neglect of effective control measures. However, these vaccinations are recommended for health workers. Supplying safe drinking water and proper disposal of excreta continue to be the most practical and effective strategy.

Significant increase in tetanus incidence have not occurred after natural disasters. Mass vaccination of population against tetanus is usually unnecessary. Better protection is maintenance of a high level of immunity in the general population by routine vaccination before the disaster occurs, and adequate wound cleaning and treatment. If tetanus immunization was received more than 5 years ago in a patient who has sustained an open wound, a tetanus toxoid booster is an effective preventive measure. In previously unimmunized injured patients, tetanus toxoid should be given only at the discretion of a physician.
routine vaccination programmes are being conducted in camps with large number of children, it is prudent to include vaccination against tetanus. Natural disasters may negatively affect the maintenance of national or regional eradication programmes against polo and smallpox. Disruption of these programmes should be monitored closely. If cold-chain facilities are inadequate, they should be requested at the same time as vaccines. The vaccination programme to be adopted should be decided at senior level only.

**Nutrition**

A natural disaster may affect the nutritional status of the population by affecting one or more components of food chain depending on the type, duration and extent of the disaster, as well as the food and nutritional conditions existing in the area before the catastrophe. Infants, children, pregnant women, nursing mothers and sick persons are more prone to nutritional problems after protracted drought or after certain types of disasters like hurricanes, floods, land or mudslides, volcanic eruptions and sea surges involving damage to crops, to stocks or to food distribution systems.

The immediate steps for ensuring that the food relief programme will be effective include: (a) assessing the food supplies after the disaster; (b) prioritizing the nutritional needs of the affected population; (c) calculating daily food rations and need for large population groups and (d) monitoring the nutritional status of the affected population.

**Rehabilitation**

The final phase in a disaster should lead to restoration of the pre-disaster conditions. Rehabilitation starts from the very first moment of a disaster too often, measures decided in a hurray, tend to obstruct re-establishment of normal conditions of life. Provisions by external agencies of sophisticated medical care for a temporary period has negative effects. On the withdrawal of such care, the population is left with a new level of expectation which simply cannot be fulfilled. In first weeks after disaster, the pattern of health needs, will change rapidly; moving from casualty treatment to more routine primary health care. Services should be reorganized and restructured. Priorities also will shift from health care towards environmental health measures. Some of them are as follows:

**Water supply**

A survey of all public water supplies should be made. This includes distribution system and water source. It is essential to determine physical integrity of system components, the remaining capacities, and bacteriological and chemical quality of water supplied.

The main public safety aspect of water quality is microbial contamination. The first priority of ensuring water quality in emergency situations is chlorination. It is the best way of disinfecting water. It is advisable to increase residual chlorine level to about 0.2-0.5 mg/litre. Low water pressure increases the risk of infiltration of pollutants into water mains. Reservoirs, mains, reservoirs and other units require cleaning and disinfection.

Chemical contamination and toxicity are a second concern in water quality and potential chemical contaminants have to be identified and analyzed.

The existing and new water sources require the following protection measures: (1) restrict access to people and animals; (2) filter away silt; (3) provide safe disposal of water after purification; (4) store water in a wide variety of safe places; (5) ensure that the maximum yield of wells and tanks is not exceeded.

In many emergency situations, water has to be trucked to disasters sites or camps. All water tanks should be inspected to determine fitness, and should be cleaned and disinfected before transporting water.

**Food safety**

Poor hygiene is the major cause of food-borne diseases in disaster situations. Where feeding programmes are used (as in shelter or camps) kitchen sanitation is of utmost importance. Personal hygiene should be monitored in individuals involved in food preparation.

**Basic sanitation and personal hygiene**

Many communicable diseases are spread through faecal contamination of drinking water and food. Hence, every effort should be made to ensure the sanitary disposal of excreta. Emergency latrines should be made available to the displaced, where toilet facilities have been destroyed. Washing, cleaning and bathing facilities should be provided to the displaced persons.

**Vector control**

Control programmes for vector-borne diseases should be intensified in the emergency and rehabilitation period, especially in areas where diseases are known to be endemic. Of special concern are dengue fever and malaria (mosquitoes), leptospirosis and tetra bleed fever (rats), typhus (lice, fleas), and plague (lice). Flood water provides ample breeding opportunities for mosquitoes. A major disaster with high mortality leaves a substantial displaced population, among whom are those requiring medical treatment and orphaned children. When it is not possible to locate the relatives who can provide care, orphans may become the responsibility of health and social agencies. Efforts should be made to reintegrate disaster survivors into society, as quickly as possible through institutional programmes coordinated by ministries of health and family welfare, social welfare, education, and NGOs.

**Disaster mitigation in health sector**

Emergency prevention and mitigation involves measures designed either to prevent hazards from causing emergency or to lessen the likely effects of emergencies. These measures include flood mitigation works, appropriate land-use planning, improved building codes, and reduction or protection of vulnerable population and structures.

In most cases, mitigation measures aim to reduce the vulnerability of the system. Medical casualties can be drastically reduced by improving the structural quality of houses, schools and other public and private buildings. Although mitigation in these sectors has clear health implications, the direct responsibility of the health sector is limited to ensuring the safety of health facilities and public health services, including water supply and sewerage systems. When water supplies are contaminated or
Policy development (2)

The policy development is "the formal statement of a course of action". Policy is strategic in nature and performs the following functions:

(a) establish long-term goals;
(b) assign responsibilities for achieving goals;
(c) establish recommended work practice; and
(d) determine criteria for decisions making.

While policies tend to be "top-down" that is authorized by higher levels, implementation of the strategies that arise from policies tends to be "bottom-up", with the higher levels assisting lower levels. The form of emergency preparedness policy varies from country to country. Six sectors are required for response and recovery strategies. These sectors are: communication, health, social welfare, police and security, search and rescue, and transport.

Personal protection in different types of emergencies (2)

In addition to considering action by rescuers, thought must be given to personal protection measures in different types of emergencies. Making people aware of what is expected of them in case of an emergency can make a large difference to the organized management efforts. By taking precautions, the individual assists the collective effort to reduce the effects of an emergency.

A number of measures must be observed by all persons in all types of emergency:
- Do not use the telephone, except to call for help, so as to leave telephone lines free for the organization of response.
- Listen to the messages broadcast by radio and the various media so as to be informed of development.
- Carry out the official instructions given over the radio or by loudspeaker.
- Keep a family emergency kit ready.

In all the different types of emergency, it is better:
- to be prepared than to get hurt;
- to get information so as to get organized;
- to wait rather than act too hastily.

FLOODS

What to do before-hand

While town planning is a government responsibility, individuals should find out about risks in the area where they live. For example, people who live in areas downstream from a dam should know the special signals (such as foghorns) used when a dam threatens to break. Small floods can be foreseen by watching the water level after heavy rains and regularly listening to the weather forecasts.

Forecasting of floods or tidal waves is very difficult, but hurricanes and cyclones often occur at the same time of year, when particular vigilance must be exercised. They are often announced several hours or days before they arrive.

During a flood
- Turn off the electricity to reduce the risk of electrocution.
- Protect people and property:
  - as soon as the flood begins, take any vulnerable people (children, the old, the sick, and the disabled) to an upper floor.
- Whenever possible, move personal belongings upstairs or to go to raised shelters provided for use in floods.
- Beware of water contamination - if the taste, colour, or smell of water is suspicious, it is vital to use some means of purification.
- Evacuate danger zones as ordered by the local authorities. It is essential to comply strictly with the evacuation advice given. Authorities will recommend that families take with them the emergency supplies they have prepared.

After a flood
When a flood is over, it is important that people do not return home until told to do so by the local authorities, who will have ensured that buildings have not been undermined by water. From then on it is essential to:
- Wait until the water is declared safe before drinking any that is untreated;
- Clean and disinfect any room that has been flooded;
- Sterilize or wash with boiling water all dishes and kitchen utensils;
- Get rid of any food that has been in or near the water, including canned foods and any food kept in refrigerators and freezers;
- Get rid of all consumables (drinks, medicines, cosmetics, etc.).

STORMS, HURRICANES AND TORNADOES

What to do before-hand
Above all it is vital that people find out about the kinds of storm liable to strike their region so that they can take optimum preventive measures, and:
- Choose a shelter in advance, before the emergency occurs - a cellar, a basement, or an alcove may be perfectly safe;
- Minimize the effects of the storm - fell dead trees, prune tree branches, regularly check the state of roofs, the state of the ground, and the drainage around houses;
- Take measures against flooding;
- Prepare a family emergency kit.

During an emergency
- Listen to the information and advice provided by the authorities.
- Do not go out in a car or a boat once the storm has been announced.
- Evacuate houses if the authorities request this, taking the family emergency package.
- If possible, tie down any object liable to be blown away by the wind; if there is time, nail planks to the doors and shutters, open the windows and doors slightly on the side opposite to the direction from which the wind is coming so as to reduce wind pressure on the house.
- If caught outside in a storm, take refuge as quickly as possible in a shelter; if there is no shelter, lie down flat in a ditch.
- In a thunderstorm keep away from doors, windows, and electrical conductors, unplug electrical appliances and television aerials. Do not use any electrical appliances or the telephone.
- Anyone who is outside should
  - Look for shelter in a building (never under a tree);
  - Keep away from fences and electric cables;
  - Kneel down rather than remain standing.

After an emergency
After the storm has subsided
- Follow the instructions given by the authorities;
- Stay indoors and do not go to the stricken areas;
- Give the alert as quickly as possible;
- Give first aid to the injured;
- Make sure the water is safe to drink and check the contents of refrigerators and freezers;
- Check the exterior of dwellings and call for assistance if there is a risk of falling objects (tiles, guttering, etc.).

EARTHQUAKES

What to do before-hand
The movement of the ground in an earthquake is rarely the direct cause of injuries; most are caused by falling objects or collapsing buildings. Many earthquakes are followed (several hours or even days later) by further tremors, usually of progressively decreasing intensity. To reduce the destructive effects of earthquakes a number of precautions are essential for people living in risk areas:
- Build in accordance with urban planning regulations for risk areas.
- Ensure that all electrical and gas appliances in houses, together with all pipes connected to them, are firmly fixed.
- Avoid storing heavy objects and materials in high positions.
- Hold family evacuation drills and ensure that the whole family knows what to do in case of an earthquake.
- Prepare a family emergency kit.

During an earthquake
- Keep calm, do no panic.
- People who are indoors should stay there but move to the central part of the building.
- Keep away from the stairs, which might collapse suddenly.
- People who are outside should stay there, keeping away from buildings to avoid collapsing walls and away from electric cables.
- Anyone in a vehicle should park it, keeping away from bridges and buildings.

After an earthquake
- Obey the authorities' instructions.
- Do not go back into damaged buildings since tremors may start again at any moment.
- Give first-aid to the injured and alert the emergency services in case of fire, burst pipes, etc.
- Do not go simply to look at the stricken areas; this will hamper rescue work.
- Keep emergency packages and a radio near at hand.
- Make sure that water is safe to drink and food stored at home is fit to eat (in case of electricity cuts affecting refrigerators and freezers).
CLOUDS OF TOXIC FUMES

What to do before-hand
People in a risk area should:
- find out about evacuation plans and facilities;
- familiarize themselves with the alarm signals used in case of emergency;
- equip doors and windows with the tightest possible fastenings;
- prepare family emergency kits.

During an emergency
- Do not use the telephone; leave lines free for rescue services.
- Listen to the messages given by radio and other media.
- Carry out the instructions transmitted by radio or other media.
- Close doors and windows.
- Stop up air intakes.
- Seal any cracks or gaps around windows and doors with adhesive tape.
- Organize a reserve of water (by filling wash basins, baths, etc.).
- Turn off ventilators and air conditioners.

After an emergency
- Comply with the authorities' instructions and do not go out until there is no longer any risk.
- Carry out necessary decontamination measures.

MAN-MADE DISASTERS

There are many disasters which have large elements of human causation either accidental or intended. These can also be divided into three categories. (a) Sudden disasters such as Bhopal Gas Tragedy in India on 3rd December 1984 in which a leakage in the storage tank of Union Carbide Pesticide Plant released tons of methyl isocyanate into the air. Wind conditions and an atmospheric inversion, along with delayed warning and a population that had not been taught the nature of risks and the appropriate response increased the impact. About 2 million people were exposed to the gas leaving about 3,000 dead. People are still suffering from the adverse effects of the gas. The second example is the accident at reactor 4 of the Chernobyl nuclear power station in the Soviet Union on April 26, 1986, which resulted in the largest reported accidental release of radioactive material in the history of nuclear power. It deposited more than 7 million curies of iodine 131, cesium 134 and 137, strontium 90 and other isotopes throughout the northern hemisphere. (b) Insidious disasters, such as insidious chemical exposure and insidious radiation exposure, as in nuclear weapons production factories, research laboratories resulting in release of radioactive substances into the air, soil and underground water. Chemical plants releasing their toxic by-products into rivers and other water sources is another example. Other form of long term and continuing human-made disaster include global warming (the "green house effect") caused by the heat-trapping gases in the atmosphere released by burning of fossil fuels, and depletion of ozone layer due to the use of the aerosolized chlorofluorocarbons etc.; and (c) Wars and civil conflicts. The latest example is the attack on twin buildings of World Trade Centre in New York in which about 6000 people lost their lives and thousands were injured. Since World War II, there have been about 127 wars and 21.8 million war-related deaths involving more than 30 per cent of civilians (3). Recently the proportion of civilians among dead has been increasing. Air-born power and wide-ranging nature of modern war puts an entire population at risk, disrupting food production and supply routes, impoverishing fragile ecosystems and forcing refugees by hundreds of thousands to flee. More than half of civilian deaths in current hostilities resulted from war-related famines. As for causes of most wars, most frequent objectives were gain of land and territories, and independence. However, civil wars, representing power conflicts within nations, have increased sharply in the twelfth century, and are now, by far the major form of warfare.

The public health response to man-made disaster is the primary prevention. I.e., prevention of occurrence of the disaster. Much can be done to prevent not only the consequences but also the occurrences of fires, explosions, crashes, and sudden chemical and radiation exposures. This includes tighter regulations of chemical plants and other hazardous facilities and insistence that the chemical plants be built away from dense populous areas. Other measures include appropriate engineering and technological measures (like building codes, dam designs, containment of toxic materials), early warning, if possible, and protection against human errors.

During the first half of the twentieth century, two world wars and many regional conflicts provided the experience for governments, to develop civil defence programmes. They were rehearsed after the introduction of nuclear weapons and massive air attacks occurring with little warning. Weapons of mass destruction are indiscriminate, killing and injuring civilians as well as military personnel, and destroying and contaminating ecosystem, over wide areas. People around the world have turned towards effort to stop the arms race and prevent nuclear war.

Disasters in India

With a wide range of topographic and climatic conditions, India is the highly disaster-prone country in Asia-Pacific region with an average of 6 major natural calamities a year. While floods, cyclones, droughts, earthquakes and epidemics are frequent from time to time, major accidents happen to railways, mines and factories causing extensive damage to human life and property.

Northern mountain regions, including the foot hills are prone to snow-storms, landslides and earthquakes. The eastern coastal areas are prone to severe floods and cyclones (Andhra Pradesh, West Bengal, Orissa, etc.). Bihar, Assam and Uttar Pradesh get major floods almost every year. Western desert areas are prone to draughts. There is hardly a year when some or the other part of the country does not face the spectre of drought, floods or cyclone. Orissa had super cyclone on 29th October 1999, when thousands lost their lives and many more became homeless. Gujarat had a severe earthquake in which about 16,480 people died and 12,000 became homeless. Indian ocean tsunami killed more than 206,000 persons in India in Dec. 2004 and major earthquake in Jammu & Kashmir (7.4 ES) left 1,500 dead and 30,000 injured, more recently, in June 2013 is Uttarakhand, cloudburst causing floods that killed about 5,748 people in Rudraprayag, and the floods in Kashmir valley in 2014. India also saw world's worst man-made disaster in 1984, when methyl isocyanate gas leaked at
Union Carbide Pesticide Plant in Bhopal killing about 3,000 people. People are still suffering from variety of diseases, as an after effect of this tragedy.

In the federal structure of India, the state governments are responsible for the execution of relief work in wake of natural disasters. Government of India plays a supportive role, in terms of supplementation of local resources to the states. An administrative system has been developed to combat and minimize the adverse impact of the natural disasters. At the centre, the Ministry of Agriculture is the nodal ministry for coordination of all activities during a natural disaster. Since health is an important part of disaster management, in the DGHS under the ministry of Health and Family Welfare there is a special wing called the Emergency Medical Relief Wing which coordinates all activities related to health.

In a vast country like India, it is not practicable for the government machinery alone, to undertake disaster reduction programmes without involvement of NGOs. Public education and community involvement plays a vital role here. As part of the International Decade for Natural Disaster Reduction, every year, the second Wednesday of October has been designated as World Disaster Reduction Day.

Indian Meteorological Department (IMD) plays a key role in warning the disaster. It has five centres in Kolkata, Bhubaneswar, Vishakhapatnam, Chennai and Mumbai for detection and tracking of cyclone storms. Satellite imagery facilities and cyclone warning radars are provided to various Cyclone Warning Centres. In addition, it has 31 special observation posts set up along east coast of India. For all ships out at sea, warnings are issued six times a day. Insat Disaster Warning System (DWS) receivers have been installed primarily in the coastal areas of Tanjil Nadu and Andhra Pradesh. This has proved very reliable form of communication system. The Snow and Avalanche Study Establishment (SASE) in Manali has been issuing warning to people about avalanches 24 to 48 hours in advance.

INTERNATIONAL AGENCIES PROVIDING HEALTH HUMANITARIAN ASSISTANCE

Every country is a potential source of health humanitarian assistance for some other disaster-sticken nation. Bilateral assistance, whether personnel, supplies or cash is probably the most important source of external aid. Several international or regional agencies have established special funds, procedures and offices to provide humanitarian assistance. United Nation’s Agencies are United Nations Office for the Coordination of Humanitarian Affairs (OCHA), World Health Organization (WHO), UNICEF, World Food Programme (WFP), Food and Agriculture Organization (FAO). Inter-governmental organizations are European Community Humanitarian Office (ECHO), Organization of American States (OAS), Centre of Coordination for Prevention of Natural Disasters in Central America, Caribbean Disaster Emergency Response Agency. Some Non-Governmental Organizations are CARE, International Committee of Red Cross, International Council of Voluntary Agencies (ICVA), International Federation of Red Cross and Red Crescent Societies (IFRC) etc.

References
Occupational health is essentially preventive medicine. The Joint ILO/WHO Committee on Occupational Health, in the course of its first session, held in 1950, gave the following definition: “Occupational health should aim at the promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations; the prevention among workers of departures from health caused by their working conditions; the protection of workers in their employment from risks resulting from factors adverse to health; the placing and maintenance of the worker in an occupational environment adapted to his physiological and psychological equipment, and, to summarize, the adaptation of work to man and of each man to his job (1).

Preventive medicine and occupational health have the same aim – the prevention of disease and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations; the levels of application of preventive measures are the same – health promotion, specific protection, early diagnosis and treatment, disability limitation and rehabilitation; the tools are the same – epidemiologic approach, statistics, health screening, health education etc. (2). Occupational health, therefore, is the application of preventive medicine in all places of employment.

In the past, it was customary to think of occupational health entirely in relation to factories and mines; hence the terms “industrial hygiene” or “industrial health” were in vogue. Modern concepts of occupational health now embrace all types of employment including mercantile and commercial enterprises, service trades, forestry and agriculture and includes the subjects of industrial hygiene, industrial diseases, industrial accidents, toxicology in relation to industrial hazards, industrial rehabilitation and occupational psychology. Occupational health in agriculture and ergonomics (human engineering) are relatively new concepts (3,4).

ERGONOMICS is now a well recognized discipline and constitutes an integral part of any advanced occupational health service. The term “ergonomics” is derived from the Greek ergon, meaning work and nomos, meaning law. It simply means: “fitting the job to the worker”. Training in ergonomics involves designing of machines, tools, equipment and manufacturing processes, lay-out of the places of work, methods of work and environment in order to achieve greater efficiency of both man and machine (5). The object of ergonomics is “to achieve the best mutual adjustment of man and his work, for the improvement of human efficiency and well-being”. The application of ergonomics has made a significant contribution to reducing industrial accidents and to the overall health and efficiency of the workers (5).

HEALTH OF THE WORKER

Industrial workers constitute only a segment of the general population, and the factors that influence the health of the population also apply equally to industrial workers, i.e., housing, water, sewage and waste disposal, nutrition, and education. A detailed consideration of these factors can be found in Chapter 2. In addition to these factors, the health of the industrial workers, in a large measure, will also be influenced by conditions prevailing in their work place. One of the declared aims of occupational health is to provide a safe ‘occupational environment’ in order to safeguard the health of the workers and to stop industrial production.

Occupational environment

By “occupational environment” is meant the sum of external conditions that influences which prevail at the place of work and which have a bearing on the health of the working population. The industrial worker today is placed in a highly complicated environment which is getting more complicated as man is becoming more ingenious. Basically, there are three types of interaction in a working environment:

(a) Man and physical, chemical and biological agents
(b) Man and machine
(c) Man and man.

MAN AND PHYSICAL, CHEMICAL AND BIOLOGICAL AGENTS

(1) Physical agents: The physical factors in the working environment which may be adverse to health are heat, cold, humidity, air movement, heat radiation, light, noise, vibrations and ionizing radiation. The factors act in different ways on the health and efficiency of the workers, singly or in different combinations. The amount of working and breathing space, toilet, washing and bathing facilities are also important factors in an occupational environment.

(2) Chemical agents: These comprise a large number of chemicals, radii dusts and gases which are potential hazards to the health of the workers. Some chemical agents cause disabling respiratory illnesses, some cause injury to skin and some may have a deleterious effect on the blood and other organs of the body. (3) Biological agents: The workers may be exposed to viral, rickettial, bacterial and parasitic agents which may result from close contact with animals or their products, contaminated water, soil or food.

MAN AND MACHINE

As Industry or factory implies the use of machines driven by power with emphasis on mass production. The
unguarded machines, protruding and moving parts, poor installation of the plant, lack of safety measures are the causes of accidents which is a major problem in industries. Working for long hours in unpleasant conditions is the cause of fatigue, backache, diseases of joints and muscles and impairment of the worker's health and efficiency.

MAN AND MAN
There are numerous psychosocial factors which operate at the place of work. These are the human relationships amongst workers themselves on the one hand, and those in authority over them on the other. Examples of psychosocial factors include the type and rhythm of work, work stability, service conditions, job satisfaction, leadership style, security, workers' participation, communication, system of payment, welfare conditions, degree of responsibility, trade union activities, incentives and a host of similar other factors, all entering the field of human relationships. In modern occupational health, the emphasis is upon the people, the conditions in which they live and work, the conditions and fears and their attitudes towards their job, their fellow-workers and employers (2).

The occupational environment of the worker cannot be considered apart from his domestic environment. Both are complementary to each other. The worker takes his worries home, and brings to his work disturbances which arise in his domestic environment. Stress at work may disturb his sleep, just as stress at home may affect his work. Severe prolonged stress, no matter where it has been aroused, may produce serious physical or mental symptoms which do not allow man to work efficiently. According to ecological approach, occupational health represents a dynamic equilibrium or adjustment between the industrial worker and his occupational environment.

OCCUPATIONAL HAZARDS
An industrial worker may be exposed to five types of hazards, depending upon his occupation:

(a) Physical hazards
(b) Chemical hazards
(c) Biological hazards
(d) Mechanical hazards
(e) Psychosocial hazards.

a. Physical hazards
(1) HEAT AND COLD: The common physical hazard in milder climates is heat. The direct effects of heat exposure are burns, heat exhaustion, heat stroke and heat cramps; the indirect effects are decreased efficiency, increased fatigue and enhanced accident rates. Many industries have local "hot spots" - ovens and furnaces, which radiate heat. Radiant heat is the main problem in foundry, glass and steel industries, while heat stagnation is the principal problem in jute and cotton textile industry (7). High temperatures are also found in mines for instance in the Kolar Gold Mines of Mysore which is hotter than the surface of the hotest part of the world (11,000 feet), temperatures as high as 65 deg. C are recorded (8). Physical work under such conditions is very stressful and impairs the health and efficiency of the workers. For gainful work involving sustained and repeated effort, a reasonable temperature must be maintained in each work room. The Indian Factories Act has not laid down any specific temperature standard. However, the work of Rao (1956, 1959) and Monkejee et al. (1953) indicate that a corrected effective temperature of 69 to 80 deg. F (20°C to 27°C) is the comfort zone in this country and temperatures above 80 deg. F (27°C) cause discomfort (7).

(b) Chemical hazards
(2) LIGHT: The workers may be exposed to the risk of poor illumination or excessive brightness. The acute effects of poor illumination are eye strain, headache, eye pain, lacrimation, congestion around the cornea and eye fatigue. The chronic effects on health include "miner's myopia". Exposure to excessive brightness or glare is associated with discomfort, annoyance and visual fatigue. Intense direct glare may also result in blurring of vision and lead to accidents. There should be sufficient and suitable lighting, natural or artificial, wherever persons are working.

(3) NOISE: Noise is a health hazard in many industries. The effects of noise are of two types: (i) Auditory effects (e.g., tinnitus, hearing loss) and (ii) Non-auditory effects which consist of nervousness, fatigue, interference with communication by speech, decreased efficiency and annoyance. The degree of injury from exposure to noise depends upon a number of factors such as intensity and frequency range, duration of exposure and individual susceptibility.

(4) VIBRATION: Vibration, especially in the frequency range 10 to 500 Hz, may be encountered in work with pneumatic tools such as drills and hammers. Vibration usually affects the hands and arms. After some months or years of exposure, the fine blood vessels of the fingers may become increasingly sensitized to cold (white fingers). Exposure to vibration may also produce injuries of the joints of the hands, elbows and shoulders (9).

(5) ULTRAVIOLET RADIATION: Occupational exposure to ultraviolet radiation occurs mainly in arc welding. Such radiation mainly affects the eyes, causing intense conjunctivitis and keratitis (welder's flash). Symptoms are redness of the eyes and pain, these usually disappear in a few days with no permanent effect on the vision or on the deeper structures of the eye (9).

(6) IONIZING RADIATION: Ionizing radiation is finding increasing application in medicine and industry, e.g., X-rays and radio-active isotopes. Important radio-isotopes are cobalt 60 and phosphorus 32. Certain tissues such as bone marrow are more sensitive than others and from a genetic standpoint, there are special hazards when the gonads are exposed. The radiation hazard is dependent on the dose, the time of exposure, the radiation energy, changes, malformation, cancer, leukaemia, depletion, ulceration, sterility and in extreme cases death. The International Commission of Radiological Protection has set the maximum permissible level of occupational exposure at 5 rem per year to the whole body (10).

b. Chemical hazards
There is hardly any industry which does not make use of chemicals. The chemical hazards are on the increase with the introduction of newer and complex chemicals. Chemical agents act in three ways: local action, inhalation and ingestion. The ill-effects produced depend upon the duration of exposure, the quantum of exposure and individual susceptibility.

(1) LOCAL ACTION: Some chemicals cause dermatitis, eczema, ulcers and even cancer by primary irritant action: some cause dermatitis by an allergic action. Some
chemicals, particularly the aromatic nitro and amino compounds such as TNT and nitrobenzene are absorbed through the skin and cause systemic effects. Occupational dermatitis is a big problem in industry. Rao and Banerji (1952) were the first to draw attention in India to the prevalence of occupational dermatitis due to machine oil, rubber, X-rays, caustic alkalis and lime (7).

(2) INHALATION: (i) DUSTS: Dusts are finely divided solid particles with size ranging from 0.1 to 150 microns. They are released into the atmosphere during crushing, grinding, abrading, loading and unloading operations. Dusts are produced in a number of industries – mines, foundry, quarry, pottery, textile, wood or stone working industries. Dust particles larger than 10 microns settle down from the air rapidly, while the smaller ones remain suspended indefinitely. Particles smaller than 5 microns are directly inhaled into the lungs and are retained there. This fraction of the dust is called "respirable dust", and is mainly responsible for pneumoconioses. Dusts have been classified into inorganic and organic dusts; soluble and insoluble dusts. The inorganic dusts are silica, mica, coal, asbestos dust, etc.; the organic dusts are cotton, jute and the like. The soluble dusts dissolve slowly, enter the systemic circulation and are eventually eliminated by body metabolism. The insoluble dusts remain, more or less, permanently in the lungs. They are mainly the cause of pneumoconiosis. The most common dust diseases in this country are silicosis and asbestosis.

(ii) GASES: Exposure to gases is a common hazard in industries. Gases are sometimes classified as simple gases (e.g., oxygen, hydrogen), asphyxiating gases (e.g. carbon monoxide), cyanide gas, sulphur dioxide, chlorine) and aromatic gases (e.g., chloroform, ether, trichlorethylene). Carbon monoxide is frequently reported in coal-gas manufacturing plants and steel industry. (iii) METALS AND THEIR COMPOUNDS: A large number of metals, and their compounds are used throughout the industry. The chief mode of entry of some of them is by inhalation as dust or fumes. The industrial physician should be aware of the toxic effects of lead, antimony, arsenic, beryllium, cadmium, cobalt, manganese, mercury, phosphorus, chromium, zinc and others. The ill-effects depend upon the duration of exposure and the dose or concentration of exposure. Unlike the pneumoconioses, most chemical intoxications respond favourably to cessation, exposure and medical treatment.

(3) INGESTION: Occupational diseases may also result from ingestion of chemical substances such as lead, mercury, arsenic, zinc, chromium, cadmium, phosphorus etc. Usually these substances are swallowed in minute amounts through contaminated hands, food or cigarettes. Much of the ingested material is excreted through faeces and only a small proportion may reach the general blood circulation.

c. Biological hazards

Workers may be exposed to infective and parasitic agents at the place of work. The occupational diseases in this category are brucellosis, leptospirosis, anthrax, hydratosis, psittacosis, tetanus, encephalitis, fungal infections, schistosomiasis and a host of others. Persons working among animal products (e.g., hair, wool, h(i)os) and agricultural workers are specially exposed to biological hazards.

d. Mechanical hazards

The mechanical hazards in industry centre round machinery, preceding and moving parts and the like. About 10 per cent of accidents in industry are said to be due to mechanical causes.

e. Psychosocial hazards

The psychosocial hazards arise from the workers' failure to adapt to an alien psychosocial environment. Frustation, lack of job satisfaction, insecurity, poor human relationships, emotional tension are some of the psychosocial factors which may undermine both physical and mental health of the workers. The capacity to adapt to different working environments is influenced by many factors such as education, cultural background, family life, social habits, and what the worker expects from employment.

The health effects can be classified in two main categories: (a) Psychological and behavioural changes: including hostility, aggressiveness, anxiety, depression, tardiness, alcoholism, drug abuse, sickness, absenteeism; (b) Psychosomatic (ill-health: including fatigue, headache, pain in the shoulders, neck and back; propensity to peptic ulcer, hypertension, heart disease and rapid aging.

Reports from various parts of the world indicate that physical factors (heat, noise, poor lighting) also play a major role in adding to or precipitating mental disorders among workers. The increasing stress on automation, electronic operations and nuclear energy may introduce newer psychosocial health problems in industry. Psychosocial hazards are therefore, assuming more importance than physical or chemical hazards.

OCCUPATIONAL DISEASES

There is no internationally accepted definition for the term "occupational disease" (3). However, occupational diseases are usually defined as diseases arising out of or in the course of employment. For convenience, they may be grouped as under:

I. Diseases due to physical agents

(1) Heat : Heat hyperpyrexia, heat exhaustion, heat syncope, heat cramps, burns and local effects
(2) Cold : Trench foot, frost bite, chilblains
(3) Light : Occupational cataract, miner's nystagmus
(4) Pressure : Caisson disease, air embolism, blast (explosion)
(5) Noise : Occupational deafness
(6) Radiation : Cancer, leukemias, aplastic anaemia, pancytopenia
(7) Mechanical : Injuries, accidents, factors
(8) Electricity : Burns.

II. Diseases due to chemical agents

(1) Gases: CO2, CO, HCN, CS2, NH3, P2O5, H2S, HCl, SO2 – these cause gas poisoning
(2) Dusts (Pneumoconiosis)

(i) Inorganic dusts:
(a) Coal dust .. Anthracosis
(b) Silica .. Silicosis
(c) Asbestos .. Asbestosis, cancer lung
(d) Iron .. siderosis
(ii) Organic (vegetable) dusts
(a) Cane fibre .. Bagassosis
(b) Cotton dust ... Byssinosis
(c) Tobacco ... Tuberculosis (11)
(d) Hay or ... Farmers' lung
grain dust

(3) Metals and their compounds
Toxic hazards from lead, mercury, cadmium, manganese, beryllium, arsenic, chromium etc.

(4) Chemicals: Acids, alkalies, pesticides

(5) Solvents: Carbon bisulphide, benzene, trichloroethylene, etc.

III. Diseases due to biological agents
Brucellosis, leptospirosis, anthrax, actinomycosis, hydatidosis, psittacosis, tetanus, encephalitis, fungal infections, etc.

IV. Occupational cancers
Cancer of skin, lungs, bladder.

V. Occupational dermatosis
Dermatitis, eczema.

VI. Diseases of psychological origin
Industrial neuritis, hypertension, peptic ulcer, etc.

PNEUMOCONIOSIS
Dust within the size range of 0.5 to 3 microns, is a health hazard producing, after a variable period of exposure, a lung disease known as pneumoconiosis, which may gradually cripple a man by reducing his working capacity due to lung fibrosis and other complications. The hazardous effects of dusts on the lungs depend upon a number of factors such as (a) chemical composition (b) fineness (c) concentration of dust in the air (d) period of exposure and (e) health status of the person exposed. Therefore, the threshold limit values for different dusts are different. In addition to the toxic effect of the dust on the lung tissues, the super-imposition of infections like tuberculosis may also influence the pattern of pneumoconiosis. The important dust diseases are silicosis, anthracosis,byssinosis, asbestosis, and farmer's lung. As no cure for the pneumoconiosis is known, it is essential to prevent these diseases from arising. A brief account of these conditions is given below:

1. Silicosis
Among the occupational diseases, silicosis is the major cause of permanent disability and mortality. It is caused by inhalation of dust containing free silica or silicon dioxide (SiO₂). It was first reported in India from the Kolar Gold Mines (Mysore) in 1947. Ever since, its occurrence has been uncovered in various other industries, e.g. mining industry (coal, mica, gold, silver, lead, zinc, manganese and other metals), pottery and ceramic industry, sand blasting, metal grinding, building and construction work, rock mining, iron and steel industry and several others. In the mines of Bihar, out of 329 miners examined, 34.1 per cent were found suffering from silicosis. In a ceramic and pottery industry, the incidence of silicosis was found to be 15.7 per cent (12). The incidence of silicosis depends upon the chemical composition of the dust, size of the particles, duration of exposure and individual susceptibility. The higher the concentration of free silica in the dust, the greater the hazard. Particles between 0.5 to 3 micron are the most dangerous because they reach the interior of the lungs with ease. The longer the duration of exposure, the greater the risk of developing silicosis. It is found that the incubation period may vary from a few months up to 6 years of exposure, depending upon the above factors.

The particles are ingested by the phagocytes which accumulate and block the lymph channels. Pathologically, silicosis is characterized by a dense "nodular" fibrosis, the nodules ranging from 3 to 4 mm in diameter. Clinically the onset of the disease is insidious. Some of the early manifestations are irritant cough, dyspnea on exertion and pain in the chest. With more advanced disease, impairment of total lung capacity (TLC) is commonly present. An X-ray of the chest shows "snowstorm" appearance in the lung fields. Silicosis is progressive and what is more important is that silicotics are prone to pulmonary tuberculosis, a condition called "silico-tuberculosis." In recent years doubts have been raised, whether silica-tuberculosis are really tubercular or purely silicotic. It is because, sputum in silico-tuberculosis rarely shows tubercle bacilli; children and women of silica-tuberculosics do not develop tuberculosis; post-mortems on silica-tuberculosics failed to prove the existence of tuberculosis disease, but showed them to be cases of pure silicosis. The pathological evidence in the two conditions is so similar that one is apt to mistake a case of silicotic to be a case of tuberculosis of lungs (13). The final answer to this question is still awaited.

There is no effective treatment for silicosis. Fibrotic changes that have already taken place cannot be reversed. The only way that silicosis can be controlled (if not altogether eliminated) is by (1) substitution, complete enclosure, isolation, hydrolasting, good house-keeping, personal protective measures and (2) regular physical examination of workers (14).

Silicosis was made a notifiable disease under the Factories Act 1948 and the Mines Act 1952.

2. Anthracosis
Previously it was thought that pulmonary "anthracosis" was inert. Studies (15) indicate that there are two general phases of anthracosis, i.e., (1) an initial stage which is labelled simple pneumoconiosis which is associated with little ventilatory impairment. This phase may require about 12 years of work exposure for its development (2) the second phase is characterised by progressive massive fibrosis (PMF); this causes severe respiratory disability and frequently results in premature death. Once a background of simple pneumoconiosis has been attained in the coal worker, a progressive massive fibrosis may develop out of it without further exposure to it. From the point of view of epidemiology, the risk of death among coal miners has been nearly twice that of the general population (15). Coal-miners' pneumoconiosis has been declared a notifiable disease in the Indian Mines Act of 1952, and also compensatable in the Workmen's Compensation (Amendment) Act of 1959.

3. Byssinosis
Byssinosis is due to inhalation of cotton fibre dust over long periods of time. The symptoms are chronic cough and progressive dyspnea, ending in chronic bronchitis and emphysema. India has a large textile industry employing nearly 35 per cent of the factory workers. Incidence of byssinosis is reported to be 7 to 8 per cent in three independent surveys carried out in Mumbai, Ahmedabad and Delhi (12).
4. Bagassosis

Bagassosis is the name given to an occupational disease of the lungs caused by inhalation of bagasse or sugarcane dust. It was first reported in India by Ganguli and Pal in 1955 in a cardboard manufacturing firm near Kolata. India has a large cane-sugar industry. The sugarcane fibre which earlier went to waste is now utilized in the manufacturing of paper, cardboard and rayon.

Bagassosis has been shown to be due to a thermophilic actinomycete for which the name Thermobifida sacchari was suggested (18). The symptoms consist of breathlessness, cough, haemoptysis and slight fever. Initially there is acute diffuse bronchialitis. Spirogram may show mottling in lungs or shadow. There is impairment of pulmonary function (17). If treated early, there is resolution of the acute inflammatory condition of the lungs. If left untreated, there is diffuse fibrosis, emphysema and bronchiectasis.

PREVENTIVE MEASURES: (1) DUST CONTROL: Measures for the prevention and suppression of dust such as wet process, enclosed apparatus, exhaust ventilation etc., should be used. (2) PERSONAL PROTECTION: Personal protective equipment (mask or respirators with mechanical filters or with oxygen or air supply) may be necessary. (3) MEDICAL CONTROL: Initial medical examination and periodic medical check-ups of the workers are indicated. (4) BAGASSE CONTROL: By keeping the moisture content above 60% per cent and spraying the bagasse with 2 per cent potassic acid, a widely used fungicide, bagasse can be rendered safe for manufacturing use (18).

5. Asbestosis

Asbestosis is the commercial name given to certain types of fibrous materials. They are silicates of varying composition; the silicates contain the oxides such as magnesium, iron, calcium, sodium and aluminium. Asbestosis is of two types - serpentine or chrysotile variety and the amphibole type. Ninety per cent of the world's production of asbestos is of the serpentine variety, which is hydrated magnesium silicate, the amphibole type contains little magnesium. The amphibole variety includes three different types: e.g., crocidolite (blue), amosite (brown), and anthophyllite (white) (9).

Asbestos fibres are usually from 20 to 100 μ in length and 0.5 μ to 6 μ in width. Asbestos fibres in the manufacture of asbestos cement, fire-proof textiles, roof tiling, brake lining, gaskets and several other items. Asbestos is mined in Andhra Pradesh (Cuddapah), Bihar, Jharkhand, Karnata, and Rajasthan - but most of it is imported from USSR, Canada, USA and South Africa.

Asbestos enters the body by inhalation, and fine dust may be deposited in the alveoli. The fibres are insoluble. The dust deposited in the lungs causes pulmonary fibrosis leading to respiratory insufficiency and death; carcinoma of the bronchus; mesothelioma of the pleura or peritoneum; and cancer of the gastro-intestinal tract. In Great Britain, an association was reported between mesothelioma and living within 1 km of an asbestos factory (19). The risk of bronchial cancer is reported to be high if occupational exposure to asbestos is combined with cigarette smoking. Mesothelioma, a rare form of cancer of the pleura and peritoneum, has been shown to have a strong association with the crocidolite variety of asbestos (9). The disease does not usually appear until after 5 to 10 years of exposure (20). The fibrosis in asbestosis is due to mechanical irritation, and is peri-bronchial, diffuse in character, and basal in location in contrast to silicosis in which the fibrosis is nodular in character and present in the upper part of the lungs. Clinically the disease is characterised by dyspnoea which is frequently out of proportion to the clinical signs in the lungs. In advanced cases, there may be clubbing of fingers, cardiac distress and cyanosis. The sputum shows "asbestos bodies" which are asbestos fibres coated with fibrin. An X-ray of the chest shows a ground-glass appearance in the lower two-thirds of the lung fields. Once established, the disease is progressive even after removal of the worker from contact (20).

The preventive measures consists of: (1) use of safer types of asbestos (chrysotile and amosite); (2) substitution of other insulators: glass fibre, mineral wool, calcium silicate, plastic foams, etc.; (3) rigorous dust control; (4) periodic examination of workers; biological monitoring (clinical, X-ray, lung function), and (5) continuing research.

6. Farmer's lung

Farmer's lung is due to the inhalation of mouldy hay or grain dust (22). In grain dust or hay with a moisture content of over 30 per cent bacteria and fungi grow rapidly, causing a rise of 'temperature to 40 to 50 deg. C. This heat encourages the growth of thermophilic actinomycetes, of which M. aperta is the main cause of farmer's lung (23). The acute illness is characterized by general and respiratory symptoms and physical signs. Repeated attacks cause pulmonary fibrosis and inevitable pulmonary damage and cor pulmonale. It is quite possible that this condition might be widespread in India considering the bulk of the population engaged in agricultural work.

LEAD POISONING

More industrial workers are exposed to lead than to any other toxic metal. Lead is used widely in a variety of industries because of its properties: (1) low boiling point (2) mixes with other metals easily to form alloys (3) easily oxidised and (4) anticorrosive. All lead compounds are toxic - lead arsenate, lead oxide and lead carbonate are the most dangerous; lead sulphide is the least toxic.

INDUSTRIAL USES: Over 200 industries are counted where lead is used - manufacture of storage batteries; glass manufacture; ship building; printing and pottery; rubber industry and several others.

NON-OCCUPATIONAL SOURCES: The greatest source of environmental (non-occupational) lead is gasoline. Thousands of tons of lead every year is exhausted from automobiles. Lead is one of the few trace metals that is abundantly present in the environment. Lead exposure may also occur through drinking water from lead pipes; chewing lead paint on window sill or toys in case of children.

MODE OF ABSORPTION: Lead poisoning may occur in three ways: (1) INHALATION: Most cases of industrial lead poisoning are due to aspiration of lead fumes or dust of lead or its compounds. (2) INGESTION: Poisoning by ingestion is of less common occurrence. Small quantities of lead trapped in the upper respiratory tract may be ingested. Lead may also be ingested in food or drink through contaminated hands. (3) SKIN: Absorption through skin occurs only in respect of the organic compounds of lead, especially tetraethyl lead. Inorganic compounds are not absorbed through the skin.

BODY STORES: The body store of lead in the average adult population is about 150 to 500 mg and blood levels
OCCUPATIONAL HEALTH

average about 25ug/100 ml. An increase to 70ug/100 ml
blood is generally associated with clinical symptoms. Normal
adults ingest about 0.2 to 0.3 mg of lead per day largely from
food and beverages (24).

DISTRIBUTION IN THE BODY: Ninety per cent of the
ingested lead is excreted in the feces. Lead absorbed from
the gut enters the circulation, and 95 per cent enters the
erythrocytes. It is then transported to the liver and kidneys
and finally transported to the bones where it is laid down
with other minerals. Although bone lead is thought to be
‘metabolically inactive’, it may be released to the soft tissues
again under conditions of bone resorption. Lead probably
exerts its toxic action by combining with essential SH-groups of
certain enzymes, for example some of those involved in
prophyrin synthesis and carbohydrate metabolism. Lead has
an effect on membrane permeability and potassium
leakage has been demonstrated from erythrocytes exposed to
lead (25).

CLINICAL PICTURE: The clinical picture of lead
poisoning or plumbism is different in the inorganic and
organic lead exposures. The toxic effects of inorganic lead
exposure are abdominal colic, colic constipation, loss of
appetite, blue-line on gums, stippling of red cells,
aema, wrist drop and foot drop. The toxic effects of
organic lead compounds are mostly on the central
nervous system - insomnia, headache, mental confusion,
lethargy, etc.

DIAGNOSIS (26, 27)
Diagnosis of lead poisoning is based on: (1) HISTORY: a
history of lead exposure (2) CLINICAL FEATURES: such
as loss of appetite, intestinal colic, persistent headache,
weakness, abdominal cramps and constipation, joint and
muscular pains, blue line on gums, anaemia, etc. (3)
LABORATORY TESTS: a) Ceproporphyrin in urine
(CPU) : Measurement of CPU is a useful screening test. In
non-exposed persons, it is less than 150 microgram/ltre.
(b) Amino leucullic acid in urine (ALA): If it exceeds 5 mg/
ltre, it indicates clearly lead absorption. (c) Lead in blood
and urine: Measurement of lead in blood or urine requires
refined laboratory techniques. They provide quantitative
indicators of exposure. Lead in urine of over 0.8 mg/ltre
(normal is 0.2 to 0.6 mg) indicates lead exposure and lead
absorption. A blood level of 70ug/100 ml is associated with
clinical symptoms. (d) Basophilic stipping of RBC: is a
sensitive parameter of the haematological response.

PREVENTIVE MEASURES
(1) Substitution: That is, where possible lead compounds
should be substituted by less toxic materials. (2) Isolation:
All processes which give rise to harmful concentration of
lead dust or fumes should be enclosed and segregated.
(3) Local exhaust ventilation: There should be adequate
local exhaust ventilation system to remove fumes and dust
promptly (4) Personal protection: Workers should be
protected by approved respirators. (5) Good house-keeping:
Good house-keeping is essential where lead dust is present.
Floors, benches, machines should be kept clean by wet
sweeping. (6) Workmg atmosphere: Lead concentration in
the working atmosphere should be kept below 2.0 mg per
10 cu. metres of air, which is usually the permissible limit or
threshold value. (7) Periodic examination of workers: All
workers must be given periodic medical examination.
Laboratory determination of urinary lead, blood lead, red
cell count, haemoglobin estimation and co-Optoporphyrrin test
of urine should be done periodically. Estimation of
basophilic stipping may also be done. An expert committee
of the WHO states that in the case of exposure to lead, it is
not only the average level of lead in the blood that is
important, but also the number of subjects whose blood
level exceeds a certain value (e.g., 70ug/ml or those ALA in
the urine exceeds 10/mg/litre) (8) Personal hygiene: Hand-
washing before eating is an important measure of personal
hygiene. There should be adequate washing facilities in
industry. Prohibition on taking food in work places is
essential. (9) Health education: Workers should be educated
on the risks involved and personal protection measures.

MANAGEMENT: The major objectives in management
of lead poisoning are the prevention of further absorption,
the removal of lead from soft tissues and prevention of
recurrence. Early recognition of cases will help in removing
them from further exposure. A saline purge will remove
unabsorbed lead from the gut. The use of d-penicillamine has
been reported to be effective. Like Ca-EDTA, it is a
chelating agent and works by promoting lead excretion
in urine. Lead poisoning is a notifiable and compensatable
disease in India since 1924.

OCCUPATIONAL CANCER
Occupational cancer is a serious problem in industry. The
sites of the body most commonly affected are skin, lungs,
bladder, and blood-forming organs.

1. Skin cancer
Pericral Pott was first to draw attention to cancer of
scrotum in chimney sweeps in 1775. It was subsequently
found that cancer of the scrotum and of the skin in other
parts of the body was caused by coal tar, X-rays, certain oils
and dyes. Statistics now show that nearly 75 per cent of
occupational cancers are skin cancer (28). Skin cancers are
an occupational hazard among gas workers, coke oven
workers, tar distillers, oil refiners, dye-stuff makers, rose
makers and in industries associated with the use of mineral
oil, pitch, tar and related compounds.

2. Lung cancer
Lung cancer is a hazard in gas industry, asbestos industry,
nickel and chromium work, arsenic roasting plants and in
the mining of radio-active substances (e.g., uranium).
Nickel, chromium, asbestos, coal tar (presumably 3-4
benzyrene), radio-active substances and cigarette-smoking
are proved carcinogens for the lungs. Arsenic, beryllium and
isopropyl oil are suspected carcinogens. More than nine-
tenths of lung cancer are attributed to tobacco smoking, air
pollution and occupational exposure.

3. Cancer bladder
Cancer bladder was first noted in man in aniline industry
in 1895. In more recent years, it was noted in the rubber
industry. It is now known that cancer bladder is caused by
aromatic amines, which are metabolized in the body and
excreted in the urine. The industries associated with cancer
bladder are the dye-stuffs and dyeing industry, rubber, gas
and the electric cable industries. The following have been
mentioned as possible bladder carcinogens: Beta-
naphthylamines, benzidine, para-amino-diphenyl, auramine
and magenta (29).

4. Leukaemia
Exposure to benzol, roentgen rays and radio-active
RADIATION HAZARDS

A number of industries use radium and other radio-active substances, e.g., painting of luminous dials for watches and other instruments, manufacture of radio-active paints. Exposure to radium also occurs in mining of radio-active ores, mine shaft workers and handling of their products. X-rays are used both in medicine and industry. Exposure to ultraviolet light occurs in arc and other electric welding processes. Infra-red rays are produced in welding, glass blowing, foundry work and other processes where metal and glass are heated to the molten state, and in heating and drying of painted and lacquered objects.

Effects of radiation

Occupational hazards due to ionizing radiation may be acute burns, dermatitis and blood dyscrasias; chronic exposure may cause malignancies and genetic effects. Lung cancer may develop in miners working in uranium mines due to inhalation of radio-active dust.

Preventive measures

(1) Inhalation, swallowing or direct contact with the skin should be avoided. Use of the X-ray badge or pocket electrometer devices.
(2) Protective clothing to prevent contact with harmful material should be used. Adequate ventilation of work-place is necessary to prevent inhalation of harmful gases and dusts. Replacement and periodic examination of workers should be done every 2 months. If harmful effects are found, the employee should be transferred to work not involving any exposure to radiation, and (7) Pregnant women should not be allowed to work in places where there is continuous exposure.

OCCUPATIONAL HAZARDS OF AGRICULTURAL WORKERS

Occupational health in agriculture sector is a new concept. From the standpoint of capital investment and number of persons employed, agriculture may be termed as “big industry”. Agricultural workers have a multitude of health problems—a fact which is often forgotten because of the widespread misconception that occupational health is mainly concerned with industry and industrialized countries. The health problems of workers in agriculture may be enumerated as below (8, 21).

(1) ZOONOTIC DISEASES: The close contact of the agricultural worker with animals or their products increases the likelihood of contracting certain zoonotic diseases such as brucellosis, anthrax, leptospirosis, tetanus, tuberculosis (bovine) and Q fever. The extent of the occupational occurrence of these diseases in most parts of the world is not known.

(2) ACCIDENTS: Agricultural accidents are becoming more frequent, even in developing countries, as a result of the increasing use of agricultural machinery. Insect and snake bites are an additional health problem in India.

(3) TOXIC HAZARDS: Chemicals are being used increasingly in agriculture either as fertilizers, insecticides or pesticides. Agricultural workers are exposed to toxic hazards from these chemicals. Associated factors such as malnutrition and parasitic infestation may increase
susceptibility to poisoning at relatively low levels of exposure.

(4) PHYSICAL HAZARDS: The agricultural worker may be exposed to extremes of climatic conditions such as temperature, humidity, solar radiation, which may impose additional stresses upon him. He may also have to tolerate excessive noise levels, inadequate ventilation and the necessity of working in uncomfortable positions for long periods of time.

(5) RESPIRATORY DISEASES: Exposure to dusts of grains, rice husks, coconut fibres, tea, tobacco, cotton, hay and wood are common where these products are grown. The resulting diseases – e.g., byssinosis, bagoassist, farmer's lung and occupational asthma, appear to be widespread.

ACCIDENTS IN INDUSTRY

Accidents are a common feature in most industries. In fact, some industries are known for accidents, e.g., coal and other mining industries, quarries, construction work. It was estimated that nearly 3 million man-days are lost yearly in India because of accidents. The worker, the loss is in terms of his wages, apart from human suffering, to the industry. It is in terms of compensation costs, provision of medical care, lowered morale, lowered production and damage to machinery and goods to the nation in terms of lost production.

CAUSES

The causes of accidents are several and may be grouped under two headings: human and environmental (33).

(a) HUMAN FACTORS: Most authorities consider human factors much more important than environmental factors in accident causation, the former being responsible for 85 per cent of all accidents (34). These factors are: (1) PHYSICAL: The physical capabilities of the worker may not meet the job requirements; his visual acuity may be inadequate; his hearing may be inadequate. (2) PSYCHOLOGICAL FACTORS: (a) Sex: Studies have shown that women are known to have less accidents than men, doing comparative jobs. In a study from the Psychological and Industrial Hygiene Section of the AI Institute of Hygiene and Public Health, Kolkata the ratio was 5:24 reportable accidents in Bengal (b) Age: Younger ages are known to be involved more in accidents than older age groups. The very old again are more prone to accidents. (c) Time: Accidents are minimum at the beginning of the day and increase gradually as fatigue sets in. (d) Experience: Approximately 50 per cent of the employees had accidents in their first 6 months of employment, 25 per cent in the 6th month and only 3 per cent subsequently in certain industrial undertakings. Thus experience is an important factor in the occurrence of accidents. (e) Working hours: An increase in accidents is found whenever the daily or weekly working hours increase. (3) PSYCHOLOGICAL: These are mental factors that might involve a person in accidents - carelessness, irritativeness, overconscientiousness, lack of experience, slow cerebration, ignorance, inexperience, emotional stress and accident proneness. Psychological factors appear to be more important factors than physical factors.

(b) ENVIRONMENTAL FACTORS: Amongst the environmental factors known to influence the incidence of accidents are the temperature, poor illumination, humidity, noise and unsafe machines. Causes directly attributable to unsafe machines account for 10-20 per cent of all accidents.

Prevention

Accident prevention is a fascinating problem. Studies have shown that 98 per cent of the accidents are preventable. The principles of accident prevention are: (1) adequate replacement examinations. (2) Inadequate job training. (3) continuing education. (4) ensuring safe working environment. (5) establishing a safety department in the organization under a competent safety engineer. (6) periodic surveys for finding out hazards. (7) careful reporting, maintenance of records and publicity.

SICKNESS ABSENTEEISM

Sickness absence is an important health problem in industry. It may seriously impede production with serious cost repercussions, both direct as well as indirect. At the production level, techniques become more sophisticated, absenteeism tends to increase the adverse repercussions. Absenteeism is a useful index in industry to assess the state of health of workers, and their physical, mental and social well-being.

INCIDENCE: India has a working force of 5 million in registered factories. Research undertaken by the National Productivity Council (N.P.C.) into absenteeism indicated a marked increase from around 8 to 13 per cent in the early 1950s to around 15 to 20 per cent or even more in recent years (35). The rate of absenteeism was reported to be 8 to 10 days per head per year (36).

CAUSES: The causes of sickness-absenteeism may not be entirely due to sickness. (a) Economic causes: Studies have shown that if the worker is entitled to sick leave with pay, he tends to avoid this privilege by reporting sick. It is so well remarked that in industry the workers declare themselves fit or unfit for work, at their choice (37). (b) Social causes: Certain social factors appear to influence sickness absenteeism in India. These are the social and family obligations such as weddings, festivals, repair and maintenance of ancestral house and similar other causes. Some of the workers who come from rural areas go back to their villages, for short or long periods, during farming and harvest seasons. (c) Medical causes: About 10 per cent of the days lost were found to be due to occupational accidents. Respiratory and alimentary illnesses have also been found to be important causes. (d) Non-occupational causes: Certain non-occupational causes such as nutritional disorders, alcoholism and drug addiction have also been found to be responsible for sickness-absenteeism.

PREVENTION: The prevention/reduction of sickness absenteeism would result in better utilization of resources and maximising the production. The methods for reducing sickness absenteeism include (1) good factory management and practices (2) adequate replacement examination and (3) good human relations and (4) application of ergonomics.

HEALTH PROBLEMS DUE TO INDUSTRIALIZATION

Industrialization implies the transformation of a peasant society into a community dependent upon the industries. It involves individual and collective technical skills for the manufacture of particular goods through highly specialised processes. There is division of work under the same roof with emphasis on mass production and community profit. In short, industrialisation means a social and economic evolution in the culture of a nation. Any such revolution is bound to carry with it some associated hazards.
The community health problems arising out of industrialisation may be enumerated as follows. (1) ENVIRONMENTAL SANITATION PROBLEMS (a) HOUSING: A rise in the number of slums and insanitary dwellings is one of the chief problems in all industrial areas due to migration of people from the countryside for employment. The effect of sub-standard housing on the health of the population is discussed elsewhere in detail. (b) WATER POLLUTION: Water pollution is one of the tragic aftermath of rapid industrialisation due to discharge of industrial wastes without treatment, into water courses. Industrial wastes may contain acids, alkalis, oils and other organic and inorganic chemicals, some of which may be toxic; synthetic detergents and radioactive substances. It requires legal, administrative and technical measures to deal with the situation. Pollution control measures should be instated in the planning stage itself in the process of industrialisation. (c) AIR POLLUTION: This is an important problem in industrial areas which may have an adverse effect on the health of the population. Air pollution is due to the discharge of toxic fumes, gases, smoke and dusts into the atmosphere. It requires proper town planning and zoning to eliminate this hazard. (d) SEWAGE DISPOSAL: There is bound to be pressure on the existing sanitation services if proper planning is not undertaken before locating industries. Lack of facilities for the disposal of sewage leads to pollution of water supply, contamination of soil with parasites and their ova. (2) COMMUNICABLE DISEASES: The main problems in industrial areas are tuberculosis, venereal diseases, and food and water borne infections. These are in addition to the specific diseases associated with specific industries. Industrial areas without proper sewage disposal have become hot-beds for filariasis owing to the breeding of the mosquito vectors in contaminated water. (3) FOOD SANITATION: The standards of food sanitation are bound to be lowered due to industrialisation, if proper precautions are not taken. Food-borne infections such as typhoid fever and viral hepatitis are all too common in India. (4) MENTAL HEALTH: Mental health problems are due to altered living conditions. People are removed from the warmth of village community life and are transplanted in an alien environment which calls for certain adjustments. Failure of adjustment leads to mental illness, psychoneurosis, behaviour disorders, delinquency, etc. (5) ACCIDENTS: Accidents are a public health problem in industrial areas due to congestion, vehicular traffic and the increased tempo of life. These accidents are in addition to those that occur in the factories. (6) SOCIAL PROBLEMS: Alcoholism, drug addiction, gambling, prostitution, increased divorces, breaking up of home, juvenile delinquency, higher incidence of crime are some of the social problems due to industrialization. (7) MORTALITY AND MORTALITY: Vital statistical rates indicate that industrial areas are characterized by high morbidity and mortality from certain diseases. For example the incidence of chronic bronchitis and lung cancer is higher in industrialized areas than in rural areas. The crude death rate and infant mortality rates tend to be high in industrial areas. India has special problems due to industrialization. It is because the level of public health is generally low, the average expectation of life is less than that in industrially advanced countries.

MEASURES FOR HEALTH PROTECTION OF WORKERS

The aim of occupational health is "the promotion and maintenance of the highest degree of physical, mental and social well-being of workers in all occupations". The measures for the general health protection of workers was the subject of discussion by an ILO/WHO Committee on Occupational Health in 1957. The Committee recommended the following (38).

1. Nutrition

In many developing countries, malnutrition is an important factor contributing to poor health among workers and low work output. Malnutrition may also affect the metabolism of toxic agents and also the tolerance mechanisms. Under the Indian Factories Act, it is obligatory on the part of the industrial establishments to provide a canteen when the number of employees exceed 250. The aim is to provide balanced diets or snacks at reasonable cost under sanitary control. It is important to combine this action with the education of the workers on the value of a balanced diet. If the worker carries his own lunch to work, provision should be made for a safe and uncentaminated place to store the food before it is eaten to avoid spoilage or contamination. Likewise, some place separate from the workroom should be provided so that the meal may be eaten in sanitary surroundings.

2. Communicable disease control

The industry provides an excellent opportunity for early diagnosis, treatment, prevention and rehabilitation. It is a general objective everywhere, to detect cases of communicable disease and to render them non-infectious to others by treatment or removal from the working environment, or both. The communicable diseases of special importance in India are tuberculosis, typhoid fever, viral hepatitis, amoebiasis, intestinal parasites, malaria and venereal diseases. There should be an adequate immunization programme against preventable communicable diseases. Anthrax, rabies fever, and Q fever are examples of communicable diseases which may be of occupational origin. Their control calls for special sanitary measures in the handling of working materials and substances.

3. Environmental sanitation

Within the industrial establishment, the following needs attention for the prevention of the spread of communicable diseases by water, food or other means: (1) WATEP SUPPLY: A sufficient supply of wholesome drinking water is one of the basic requirements in all industrial establishments. The common glass tumbler for drinking water should be abandoned as it spreads infection. Installation of drinking water fountains, at convenient points should be encouraged. (2) FOOD: If food is sold, its sanitary preparation, storage and handling are essential. Education of food handlers and other measures may be necessary to prevent outbreaks of gastro-intestinal disease. (3) TOILET: There should be sufficient number of latrines and urinals of the sanitary type, separate for males and females, conveniently situated. It is recommended that there should be at least one sanitary convenience for every 25 employees (males and females separate) for the first 100 employees, and thereafter one for every 50. Garbage and waste disposal should be such as to avoid the breeding of flies and vermin. (4) GENERAL PLANT CLEANSINESS: The walls, ceilings and passages should be painted with water washable paint and repainted at least once in 3 years and washed at least once in every 6 months. The dust which settles down on the floor and machinery should be promptly
removed by vacuum cleaners or by wetting agents before it is redistributed into the atmosphere by the vibration of the machinery. A high standard of general cleanliness is one of the fundamentals of accident prevention. It also contributes to the efficiency and high morale of the workers. Every floor space and public space are essential to prevent not only respiratory infections but also to ensure a comfortable working environment. In a factory, the floor space is a minimum of 500 cu. ft. of space for every worker; space more than 14 feet above the floor level is not to be taken into consideration. Lighting: The results of poor industrial illumination are workers' eye fatigue, increased accidents, decreased production and more rejections of finished products. Furthermore, defective illumination over a long period of time may result in permanent impairment of vision. There should be sufficient and suitable lighting, natural or artificial, in every part of a factory where workers are working or passing through. The standards of illumination for different kinds of work have been set out. Precision work for a high degree of accuracy may require 50-75 foot candles; where people work regularly, 6 to 12 foot candles may be sufficient. Illumination in corridors and passages should be at least 0.5 foot candles.

4. Mental health

The objective of an occupational health service is not only to keep the workers physically healthy, but mentally and psychologically stable. Industrial workers are susceptible to the effects of low, recognition, rejection, job satisfaction, rewards and discipline. The many-hourly era is now disappearing from industry. The workers, individually or collectively, like to be recognized, to have a measure of control over their own affairs, like the opportunity to develop skills appropriate to their individual capacity. The goals of mental health in industry are: (1) to promote the health and happiness of the workers, (2) to detect signs of emotional stress and strain and to secure relief of stress and strain where possible, (3) the treatment of employees suffering from mental illness, and (4) the rehabilitation of those who become ill.

5. Measures for women and children

Women workers receive special protection because (1) the developing embryo may be more susceptible to noxious agents than the exposed mother (e.g., in the case of methylbenzene poisoning), (2) females may be less suited for some work tasks than men; pregnancy may decrease the capacity to cope with many work factors, (3) women tend to be more sensitive to the effects of industrial hazards and men also restrict their nourishment in difficult economic circumstances, (4) the infant mortality is higher amongst children of women employed in industrial work.

The following types of protection are available for women workers in India: (1) Expectant mothers are given maternity leave for 12 weeks, of which 6 weeks precede the expected date of confinement; during this period they are allowed 'maternity benefit', which is a cash payment, under the Employee's State Insurance Act, 1948. (2) Provision of free antenatal, natal and postnatal services. (3) The Factories Act (Section 66) prohibits night work between 7 p.m. and 6 a.m.: Section 34 prohibits carrying of excessive weights beyond a certain schedule which has been laid down. (4) The Indian Mines Act (1923) prohibits work underground. (5) The Factories Act 1976 provides for creches in factories where more than 30 women workers are employed, and also prohibits the employment of women and children in certain dangerous occupations. Regarding protection of children, the Constitution of India declared: "No child below the age of fourteen shall be employed to work in any factory or mine or engaged in any other hazardous employment." (Chapter III, Fundamental Rights — Article 24).

6. Health education

Health education is a basic health need. It is an important health promotional measure. Health education in the industrial setting should be envisaged at all levels — the management, the supervisors, the workers, the trade union leaders and the community. The content varies from matters of personal hygiene and protection to participation of the workers in the planning and operation of the total health service programme in industry.

7. Family planning

Family planning is now recognized as a decisive factor for the quality of life, and this applies to industrial workers also. The workers must adopt the small family norm.

PREVENTION OF OCCUPATIONAL DISEASES

The various measures for the prevention of occupational diseases may be grouped under three heads: medical, engineering and statutory or legislative.

1. MEDICAL MEASURES

1. Pre-placement examination

Pre-placement examination is the foundation of an efficient occupational health service. It is done at the time of employment and includes the worker's medical, family, occupational and social history, a thorough physical examination and a battery of biological and radiological examinations, e.g., chest X-ray, electro-cardiogram, vision testing, urine and blood examination, special tests for endemic disease. A fresh recruit may either be totally rejected or given a job suited to his physical and mental abilities. The purpose of preplacement examination is to place the right man in the right job, so that the worker can perform his duties efficiently without detriment to his health. This is ergonomics. The following is a list of some occupations in which it is risky to employ men suffering from certain diseases (39).
5. Supervision of working environment

Periodic inspection of working environment provides information of primary importance in the prevention of occupational diseases. The physician should pay frequent visits to the factory in order to acquaint himself with the various aspects of the working environment such as temperature, lighting, ventilation, humidity, noise, cubic space, air pollution and sanitation which have an important bearing on the health and welfare of the workers. He should be acquainted with the raw materials, processes and products manufactured. He should also study the various aspects of occupational physiology such as occurrence of fatigue, night-work, shift-work, weight carried by the workers and render advice to the factory management on all matters connected with the health and welfare of the workers. For studies of this kind the physician should enlist the cooperation of safety engineers, industrial hygienists and psychologists.

6. Maintenance and analysis of records

Proper records are essential for the planning, development and efficient operation of an occupational health service. The worker's health record and occupational disability record must be maintained. Their compilation and review should enable the service to watch over the health of the workers, to assess the hazards inherent in certain types of work and to devise or improve preventive measures.

7. Health education and counselling

Ideally, health education should start before the worker enters the factory. All the risks involved in the industry in which he is employed and the measures to be taken for personal protection should be explained to him. The correct use of protective devices like masks and gloves should also be explained. Simple rules of hygiene – hand-washing, paring the nails, body cleanliness and cleanliness of clothes, should be impressed upon him. He should be frequently reminded about the dangers in industry through the media of health education such as charts, posters and handbills. The purpose of health education is to assist the worker in his process of adjustment to the working, social and community environment.

2. ENGINEERING MEASURES

1. Design of building

Measures for the prevention of occupational diseases should commence in the blue-print stage. The type of floor, walls, height, ceiling, roof, doors and windows, cubic space are all matters which should receive attention in the original plan of the building which is put up by the industrial architect. Once the building is constructed, it would be difficult to introduce alterations without much trouble and expense.

2. Good house-keeping

Good house-keeping is a term often applied to industry, and means much the same as when used domestically. It covers general cleanliness, ventilation, lighting, washing, food arrangements and general maintenance. Good housekeeping is a fundamental requirement for the control or elimination of occupational hazards. It also contributes to efficiency and morale in industry. The walls, ceilings, and passages should be white-washed at least once a year. The
dust which settles down on the floor, ledges, beams, machinery and other stationary objects should be promptly removed by vacuum cleaners or by wetting agents. Masks, gloves, aprons and other protective equipment should be kept clean and in a state of good repair. To prevent accidents, the right type of mask be in use to the type of dust. Not only the inside, but the outside of the plant should also be kept clean and tidy.

3. General ventilation

There should be good general ventilation in factories. It has been recommended that in every room of a factory, ventilating openings shall be provided in the proportion of 5 sq. feet for each worker employed in such room, and the openings shall be such as to admit a continued supply of fresh air. In rooms where dust is generated there should be an efficient exhaust ventilation system. Good general ventilation decreases the air born hazard to the workers, especially hazards from dusts and gases. The Indian Factories Act has prescribed a minimum of 500 cu. ft. of air space for each worker.

4. Mechanization

The plant should be mechanized to the fullest possible extent to reduce the hazard of contact with harmful substances. Dermatitis can be prevented if hand-mixing is replaced by mechanical devices. Acids can be conveyed from one place to another through pipes. There may be other similar situations where mechanization can be substituted for hand-operation.

5. Substitution

By substitution is meant the replacement of a harmful material by a less harmful one, or one of lesser toxicity. A classical example is the substitution of white phosphorus by phosphorus sesquisulfide in the match industry, which resulted in the elimination of needle jaw (Phosy Jaw). Zinc or iron paints can be used in place of harmful lead paints; silver salts can be used in place of mercury salts; acetone can be used in place of benzene. But substitution is not always possible in industry. Where possible, it should be used to the fullest possible extent.

6. Dusts

Dusts can be controlled at the point of origin by water sprays, e.g., wet drilling of rock. Inclusion of a little moisture in the materials will make the processes of grinding, slaking and mixing competitively dust-free. Wet methods should be tried to control dust before more elaborate and expensive methods are adopted.

7. Enclosure

Enclosing the harmful materials and processes will prevent the escape of dust and fumes into the factory atmosphere. Fume and dust exhausting grinding machinery can be completely enclosed. Such enclosed units are generally combined with exhaust ventilation.

8. Isolation

Sometimes it may be necessary to isolate the offensive process in a separate building so that workers not directly connected with the operation are saved from exposure. Isolation may not be only in space, but also in the fourth dimension of time. Certain operations can be done at night in the absence of the usual staff.

9. Local exhaust ventilation

By providing local exhaust ventilation dusts, fumes and other injurious substances can be trapped and extracted "at source" before they escape into the factory atmosphere. The heart of the local exhaust ventilation is the hood which is placed as near as possible to the point of origin of the dust or fume or other impurity. Dusts, gases and fumes are drawn into the hood by suction and are conveyed through ducts into collecting units. In this way, the breathing zone of workers may be kept free of dangerous dust and poisonous fumes.

10. Protective devices

Respirators and gas masks are among the oldest devices used to protect workers against air-borne contaminants and they are still used for that purpose. There are two classes of respirators: (i) those which remove contaminants from air, and (ii) those which fresh air is supplied. The wearers should know what kind to use, and when and how to use. Respiratory devices should not be used as substitute for other control methods. The other protective devices comprise ear plugs, ear muffs, helmets, safety shoes, aprons, gloves, gum boots, barrier crease, screens and goggles. The worker should be instructed in the correct use of protective devices.

11. Environmental monitoring

An important aspect of occupational health programme is environmental monitoring. It is concerned with periodical environmental surveys, especially sampling the factory atmosphere to determine whether the dusts and gases escaping into the atmosphere are within the limits of permissible concentration. The use of "permissible limits" has played an important part in reducing occupational exposure to toxic substances. Thermal environment, ventilation, lighting would also have to be monitored. Such monitoring should be done by joint collaboration of doctors and engineers.

12. Statistical monitoring

Statistical monitoring comprises review at regular intervals of collected data on health and environmental exposure of occupational groups. The main objective of these reviews is to evaluate the adequacy of preventive measures and occupational health criteria, including permissible exposure levels.

13. Research

Research in occupational health offers fertile ground for study which can provide a better understanding of the industrial health problems. There are two kinds of research — pure research and research for the improvement of, or in connection with a manufactured product. Both are important. Study of the permissible limits of exposure to dusts and toxic fumes, occupational cancer, accident prevention, industrial fatigue and vocational psychology are some aspects of research in occupational health.

3. LEGISLATION

Society has an obligation to protect the health of the worker engaged in diverse occupations. It has grown out of the realisation that the worker is more important than the machine which he operates. The worker cannot be permitted to endanger his life and limb in an occupation,
while the employer makes a fortune. Factory laws, therefore, have been framed in every country to govern the conditions in industry and to safeguard the health and welfare of the worker. The most important factory laws in India today are:

1. The Factories Act, 1948
2. The Employees’ State Insurance Act, 1948

There are other specialized Acts adapted to the particular circumstances of the industry, e.g., the Mines Act, the Plantation Act, the Minimum Wages Act, the Maternity Benefit Act, etc. All these Acts lay down certain standards to which the employer must comply to ensure health and safety to workers.

The Factories Act, 1948

The first Indian Factories Act dates as far back as 1881. The Act was revised and amended several times, the latest being the Factories (Amendment) Act, 1987. A brief description of the Act is given below:

1. SCOPE: The Act defines factory as an establishment employing 10 or more workers where power is used, and 20 or more workers where power is not used. There is no distinction between perennial and seasonal factories. The 1976 amendment modifies the definition of the term ‘worker’ so as to include within its meaning contract labour employed in the manufacturing process. The Act applies to the whole of India except the State of Jammu and Kashmir. The State Governments are authorized to appoint the Chief Inspector of Factories as many Additional Chief Inspectors, Joint Chief Inspectors, Deputy Chief Inspectors and Inspectors as they think fit to enforce the provisions of the law.

2. HEALTH, SAFETY AND WELFARE: (Chapter III, IV, IVA, & V). Elaborate provisions have been made in the Act with regard to health, safety and welfare of the workers. In addition to such matters as cleanliness, lighting and ventilation, the Act provides for the treatment of wastes and effluents so as to render them innocuous, and for their disposal, the elimination of dusts and fumes, the provision of spigots, control of temperature, supply of cool drinking water during summer and for the employment of cleaners to keep the water closets clean. A minimum of 500 Cu.ft of space for each worker has been prescribed (not taking into account space more than 14 feet above the ground level). For factories installed before the 1948 Act, a minimum of 350 Cu.ft of space has been prescribed.

The Act also prescribes in detail the precautions which should be taken for ensuring the safety of workers. Some of the safety provisions relate to the casing of new machinery, devices for cutting off the power, hoists and lifts, cranes and other lifting devices, protection of the eye and precautions against dangerous fumes, explosive and inflammable material. The Act provides that no worker shall be required to lift or carry loads which are likely to cause him injury. The State Governments are empowered to prescribe maximum weights which may be lifted or carried by men, women and children. The 1976 amendment (Section 40 B) provides for the appointment of ‘Safety Officers’ in every factory wherein 1,000 or more workers are ordinarily employed.

The Act contains a separate Chapter (Chapter V) relating to specific welfare measures, e.g., washing facilities, facilities for storing and drying clothes, facilities for sitting, first-aid appliances, shelters, rest-rooms and lunch rooms, canteens and creches. The Act specifies that wherein more than 250 workers are ordinarily employed, a canteen shall be provided. The 1976 amendment provides for creches in every factory wherein more than 30 women workers are ordinarily employed. In every factory wherein 500 or more workers are ordinarily employed, there should be a Welfare Officer.

3. EMPLOYMENT OF YOUNG PERSONS: The Act prohibits employment of children below the age of 14 years and declares persons between the ages 15 and 18 to be adolescents. Adolescents should be duly certified by the “Certifying Surgeons” regarding their fitness for work. Restrictions have been laid down on employment of women and children in certain dangerous occupations. Child who has not completed his fourteenth year of age has been restricted from employment in any factory. Adolescent employee is allowed to work only between 6 A.M. & 7 P.M.

4. HOURS OF WORK: The Act has prescribed a maximum of 48 working hours per week, not exceeding 9 hours per day with rest for at least 1½ hour after 5 hours of continuous work. For adolescents, the hours of work have been reduced from 5 to 4½ per day. The 1976 amendment makes a provision to increase the spread-over period of work (including rest intervals) of an employee in a factory upto 12 hours from the existing 10½ hours. The total number of hours of work in a week including overtime shall not exceed 60.

5. LEAVE WITH WAGES: The Act lays down that besides weekly holidays, every worker will be entitled to leave with wages after 12 month’s continuous service at the following rate: adult – one day for every 20 days of work; children – one day for every 15 days of work. The leave can be accumulated up to 30 days in case of adults and 40 days in case of children.

6. OCCUPATIONAL DISEASES: It is obligatory on the part of the factory management to give information regarding specified accidents which cause death, serious bodily injury or regarding occupational diseases contracted by employees. The Act gives a schedule of notifiable diseases. The 1976 amendment includes Byssinosis, Asbestosis, occupational dermatitis and noise-induced hearing loss among the list of notifiable diseases and provides for enquiry in every case of a fatal accident. Provision has also been made in the 1976 amendment for safety and occupational health surveys in factories and industries.

7. EMPLOYMENT IN HAZARDOUS PROCESSES: The Central Govt. has incorporated a new Chapter IVA by the Factories (Amendment) Act, 1987, relating to hazardous processes. Site Appraisal Committee consisting of Chief Inspector and other members, not more than 14 in number, for examination of service conditions of employees is a factory, involving hazardous processes, is to be constituted for recommendation. Specific responsibility of the occupier in relation to hazardous processes were also made with workers’ participation in safety management. List of industries involving hazardous processes is prescribed in 1st schedule of the Act.

The Employees State Insurance Act, 1948 (40)

The ESI Act passed in 1948 (amended in 1975, 1984, 1989 and 2010) is an important measure of social security and health insurance in this country. It provides for certain cash and medical benefits to industrial employees in cases of sickness, maternity and employment injury.
SCOPE:
The Act extends to the whole of India. The ESI Act of 1948 covers power -using factories other than seasonal factories wherein 10 or more persons were employed (excluding mines, railways and defence establishments). The provisions of the ESI Corporation, Act 25 of 1948 were extended to the following new classes of establishments:

a) Small factories employing 10 or more persons, whether power is used in the process of manufacturing or not.

b) Shops;

c) Hotels and restaurants;

d) Cinemas and theatres;

e) Road motor transport establishments; and

f) Newspaper establishments.

g) The scheme has been extended to private medical and educational institutions employing 20 or more persons in some states.

With effect from 1.5.2010 the Act covers all employees – manual, clerical, supervisory and technical getting upto Rs. 15,000 per month. The provisions of the Act can be extended to any other agricultural or commercial establishment.

ADMINISTRATION
The administration of the ESI Scheme under the Act is entrusted to an autonomous body called the ESI Corporation. The Union Minister for Labour is the Chairman and the Secretary to Govt. of India Ministry of Labour is the Vice-Chairman of this corporation. It consists of members representing Central and State Governments, employers and employees’ organisations, medical profession and Parliament. There is a Standing Committee, constituted from the members of the Corporation, which acts as an executive body for the administration of the Scheme. The chief executive officer of the Corporation is the Director General who is assisted by four Principal Officers –

(1) Insurance Commissioner (2) Medical Commissioner
(3) Financial Commissioner (4) Actuary.

There is a Medical Benefit Council which is headed by the Director General of Health Services, Government of India who is assisted by the Medical Commissioner in all matters relating to medical relief. Besides the head office in New Delhi, the corporation has 23 regional offices and 26 sub-regional offices at 2 divisional offices and 624 branch offices, 197 cash offices and 400 pharmacies all over the country for the administration of the scheme.

Given the huge number of beneficiaries – about 720 lakhs by 31.3.13 – the corporation has set up a wide spread network of service outlakes for prompt delivery of benefits in cash and kind that includes full medical care. ESI gives coverage to about 185 lakh family units of about 165 lakh employees including about 26.79 lakh females, as on 31.3.13.

Medical facilities are provided through a network of 1384 ESI dispensaries, over 2100 panel clinics, 307 diagnostic centres, besides 151 ESI hospitals and 42 hospital annexes with over 27,000 beds. For providing super-speciality medical care the corporation has tie up arrangements with advanced medical institutions in the country, both in public and private sector. The medical benefit is administered with the active co-operation of state governments.

The payment of cash benefits is made at the grass root level through as many as 624 branch offices, 197 cash offices that function under the direct control of the corporation.

There are 406 inspection offices throughout the country to inspect factories and for checking insurability of employees and correct payment of contributions (41).

FINANCE
The scheme is run by contributions by employees and employers and grants from Central and State Governments. The employer contributes 4.75 per cent of total wage bill; the employee contributes 1.75 per cent of wages (revised rates w.e.f. 1.1.97). Employees getting daily wages of below Rs.70 are exempted from contribution of payment. The State Government’s share of expenditure on medical care is 1/8 of total cost of medical care; the ESI Corporation’s share of expenditure on medical care is 7/8 of total cost of medical care.

BENEFITS TO EMPLOYEES
The Act has made provision for the following benefits to insured persons or, to other dependants as the case may be:

(1) Medical benefit
(2) Sickness benefit
(3) Maternity benefit
(4) Disability benefit
(5) Dependant’s benefit
(6) Funeral expenses
(7) Rehabilitation allowance.

1. Medical benefit
Medical benefit consists of “full medical care” including hospitalisation, free of cost, to the insured persons in case of sickness, employment injury and maternity. The services comprise :- (1) out-patient care (2) supply of drugs and dressings (3) specialist services in all branches of medicine (4) pathological and radiological investigations (5) domiciliary services (6) antenatal, natal and postnatal services (7) immunisation services (8) family planning services (9) eye, ear, nose, throat services (10) ambulance services (11) health – education and (12) in-patient treatment. In complicated cases where specialized treatment is necessary, patients are sent for institutional treatment even outside their State at the expense of the ESI Corporation.

Medical care is provided either directly through the agency of ESI hospitals and dispensaries, or indirectly through a panel of private medical practitioners (panel system) appointed as “insurance medical practitioners”. DIRECT PATTERN : (1) In areas having a concentration of 1,000 or more employees’ family units, service dispensaries are established with full-time medical and para-medical personnel. On an average, a doctor will attend to about 80 cases in the out-patient department per day, and makes one home visit a day. (2) In areas where the employees are less than 750, part-time ESI dispensaries are established. (3) If the residential concentration of employees is scattered over a long distance, mobile dispensaries are established. INDIRECT PATTERN: This is known as “panel system”. Registered medical practitioners designated as Insurance Medical Practitioners are appointed to provide medical care.

Medical care is also extended to families of workers where requisite arrangements could be made. A start has been made by providing “restricted medical care”, i.e., only out-patient care. Where facilities are available “expanded medical care” i.e., full medical care short of hospitalization is given.
OTHER MEDICAL FACILITIES: (1) Dentures, spectacles and hearing aids are provided free to patients who are incapacitated due to employment injury (2) Artificial limbs are provided free to insured persons who lose their limbs in an employment injury or otherwise (3) Special appliances such as hernia belts, walking canes, surgical boots, spinal braces and jackets are provided as prescribed by specialists.

COST OF MEDICAL BENEFIT: The per capita cost of medical benefit under the ESI Scheme has been steadily increasing. It was Rs. 23.79 in 1961–62, Rs. 58.91 in 1969–70, Rs. 67.53 in 1973–74, Rs. 406.78 in 1992–93 and Rs. 905 in 2000–01, and has been rising further since then. Expenditure on medical benefit was Rs. 4058 crores in 2012–13.

2. Sickness benefit

It consists of periodic cash payment to an insured person in case of sickness, if his sickness is duly certified by an Insurance Medical Officer or Insuree Medical Practitioners. The benefit is payable for a maximum period of 91 days, in any continuous period of 365 days, the daily rate being about 50% of the average daily wages. A person receiving the sickness benefit is required to remain under medical treatment provided under the Act.

EXTENDED SICKNESS BENEFIT: In addition to 91 days of sickness benefit, insured persons suffering from certain long-term diseases are entitled to Extended Sickness Benefit as shown below, for a maximum period of two years.

3. Diseases for which Extended Sickness Benefit with effect from 1.1.2000 is payable, in case where the insured person has been in continuous employment for 2 years:

I. Infectious Diseases
   1. Tuberculosis.
   2. Leprosy.
   3. Chronic empyema.
   4. AIDS.

II. Neoplasms
   5. Malignant diseases.

III. Endocrine, Nutritional and Metabolic Disorders

IV. Disorders of Nervous Systems
   7. Monoplegia.
   8. Hernioplegia.
   11. Intracranial space occupying lesion.
   13. Parkinson’s disease.
   15. Immature cataract with vision 6/60 or less.
   17. Glaucoma.

V. Diseases of Cardiovascular System
   18. Coronary Artery Disease
      a. Unstable angina.
      b. Myocardial infarction with ejection less than 45%.
   19. Congestive Heart Failure – Left, Right.
   20. Cardiac Valvular diseases with failure/complications.
   22. Heart disease with surgical intervention, alongwith complications.

VI. Chest Diseases
   23. Bronchiectasis.
   24. Interstitial Lung Disease.
   25. Chronic Obstructive Lung Diseases (COPD) with congestive heart failure (Cor Pulmonale).

VII. Diseases of the Digestive System

VIII. Orthopaedic Diseases
   27. Dislocation of vertebra/prolapse of intervertebral disk.
   28. Non-union or delayed union of fracture.
   29. Post Traumatic Surgical amputation of lower extremity.
   30. Compound fracture with chronic osteomyelitis.

IX. Psychosis
   31. Sub-group under this head are listed for clarification:
      a. Schizophrenia.
      b. Endogenous depression.
      c. Manic Depressive Psychosis (MDP).
      d. Dementia.

X. Others
   32. More than 20% burns with infection/complication.
   33. Chronic renal failure.
   34. Reynold’s disease/Burger’s disease.

The insured person is protected from dismissal or discharge from service by the employer during the period of sickness.

Cash benefit is also payable to insured persons in the productive age group for undergoing sterilisation operation, viz, vasectomy/tubectomy.

- Enhanced sickness benefit is payable to insured women for 14 days for tubectomy and for 7 days in case of vasectomy in respect of male IPs.
- The amount payable is double the standard sickness benefit rate, that is, equal to full wages.

3. Maternity benefit

The benefit is payable in cash to an insured woman for confinement/miscarriage or sickness arising out of pregnancy/confinement or premature birth of child or miscarriage. For confinement, the duration of benefit is 12 weeks (84 days), for miscarriage 6 weeks and for sickness arising out of confinement etc., 30 days. The benefit is allowed at about full wages. The rate of confinement expenses has been increased from Rs. 2,500 to Rs. 5,000 per confinement.

4. Disablement benefit

The Act provides for cash payment, besides free medical treatment, in the event of temporary or permanent disablement as a result of employment injury as well as
occupational diseases. The rate of temporary disablement benefit is about 90 per cent of the wages as long as the temporary disablement lasts. In case of total permanent disablement, the insured person is given life pension worked out on the basis of loss of earning capacity determined by a medical board, while in cases of partial permanent disablement a portion of it is granted as life pension.

5. Dependant's benefit

In case of death, as a result of employment injury, the dependants of an insured person are eligible for periodical payments. Pension at the rate of 90 per cent of the wages is payable, shared by dependants in a fixed ratio, on monthly basis in accordance with the prescribed share. An eligible son or daughter is entitled to dependant's benefit up to the age of 18; the benefit is withdrawn if the daughter marries earlier.

6. Funeral expenses

Funeral benefit is a cash payment payable on the death of an insured person towards the expenses on his funeral, the amount not exceeding Rs. 70,000/- w.e.f. 1.4.11.

7. Rehabilitation

On monthly payment of Rs 10, the insured person and his family members continue to get medical treatment after permanent disablement, or retirement.

The ESI scheme has been implemented in 30 States/ Union territories. The Scheme, by 31.03.13, covered 165.04 lakhs employees; including 26.79 lakhs women, and the total number of beneficiaries was around 720 lakhs (40). Covered employees in non-implemented areas were 13.89 lakhs.

Benefits to employers

(1) Exemption from the applicability of Workmen's Compensation Act 1923
(2) Exemption from Maternity Benefit Act 1961
(3) Exemption from payment of Medical allowance to employees and their dependants or arranging for their medical care
(4) Rebate under the Income Tax Act on contribution deposited in the ESI Account
(5) Healthy work-force.

As on 31.03.2013, about 6.66 lakhs employers were covered under the scheme (41).

RAJIV GANDHI SHRAMIK KALYAN YOJNA (41)

The ESI Corporation has launched a new Yojna for the employees covered under the ESI scheme. This scheme provides an unemployment allowance for the employees covered under ESI scheme who are rendered unemployed involuntarily due to retrenchment/closure of factory etc., after fulfilling certain eligibility conditions. The scheme came into effect from 1st April, 2005.

As per this scheme, an insured person going out of insurable employment involuntarily, on account of closure of a factory or establishment, retrenchment, or permanent invalidity arising out of non-employment injury, after rendering insurable employment and having contributed under the scheme for five or more years, is entitled to claim unemployment allowance for maximum period of 6 months during his/her entire service.

The allowance can be availed in one spell or in different spells of not less than one month.

The daily rate of unemployment allowance is the "standard benefit rate" as specified in the table on standard benefit rates under rule-54 of ESI (Central) Rules, 1950 corresponding to the average daily wage drawn by the insured person.

During the period for which a person is entitled for unemployment allowance, he is also eligible for medical care for illness and hospitalisation from ESI dispensaries, ESI panel clinics and ESI hospitals to which he/she was attached prior to the date of loss of employment.

OCCUPATIONAL HEALTH IN INDIA

The trend in India is towards industrialization. As industries develop, both in size and complexity, occupational health will pose new and more difficult problems. The National Government have recognised the need for protecting the health of the workers. The Directive Principles of State Policy, in the Indian Constitution are important in this context. The relevant paragraphs are:

(a) "The State shall, in particular, direct its policy towards securing that the health and strength of the workers, man, woman, and the tender age of the children are not abused, and that citizens are not forced by economic necessity to enter avocations unsuited to their strength.

(b) The State shall make provisions for securing just and humane conditions of work".

To assess the health conditions of the workers, a number of inquiries have been conducted and were submitted to the Government of India by many experts. The important reports in this connection are: Adarsh's Report of Health insurance for Industrial Workers (1945); Report of the Health Survey and Development Committee (1946); Report of the Health of the Industrial Workers (Thomas Bedford, 1945) and Report of the Health of Workers in Plantation (Jones, 1947). The Government of India have given practical shape to some of the recommendations contained in these report and have introduced certain legislative measures pertaining to both the curative and preventive aspects of occupational health. Most important among these measures are the Indian Factories Act 1948, the Coal Mines Labour Welfare Act (1947) and the Employees State Insurance Act (1948).

At present, there is no comprehensive occupational health service in India. However, there are various organizations active in the field of occupational health. The Organization of the Chief Adviser of Factories - now Directorate General, Factory Inspection and Advisory Service - was set up in 1945, to function as an integrated service to advise the Government, industries, and other interests concerned in matters relating to health, welfare and safety of industrial workers. The Organization deals with questions relating to the administration of the Factories Act and other Acts and the rules framed thereunder and the training of Factory inspectors.

For scientific study of the various aspects of occupational health, particularly the "human factor" in industry, the Central Labour Institute was set up in Mumbai in 1960. Three Regional Labour Institutes at Kanpur, Kolkata and Chennai have also been set up. These institutes are dealing with a variety of activities important in the field of safety and
health. They have (a) a Museum of Industrial Health, Safety and Welfare (b) Industrial Hygiene Laboratory (c) Training section (d) Library cum Information Centre (e) Industrial psychology and (f) Occupational Physiology sections.

At the State level, the Departments of Health and Labour, through the Chief Inspector of Factories and Industrial Health Inspection Service are rendering assistance by making studies and undertaking surveys at the plant level and enforcing the legal standards laid down in the various Acts.

In addition to the above, the following Research Institutes are active in the field of occupational health: (1) The Central Mining and Research Station, Dhanbad under the Council of Scientific and Industrial Research (CSIR). (2) Industrial Toxicology Research Centre, Lucknow under the CSIR. (3) Occupational Health Research Institute, Ahmedabad under the Indian Council of Medical Research (4) National Environmental Engineering Research Institute at Nagpur (5) The All India Institute of Hygiene and Public Health, Kolkata. (6) Indian Institute of Technology, Kanpur. Besides these, the Indian Council of Medical Research has an occupational health division. The Indian Association of Occupational Health is playing an important role in the promotion of occupational health.

"Human genetics is much more than the study of inborn abnormalities."

The basic principles of genetics were laid down by Mendel and Galton towards the close of the 19th century. But it is only during the past few years the science of genetics including human genetics has made rapid progress. The discovery of the biological role of nucleic acids, the uncovering of the structure of genetic information and its role in regulating life processes are discoveries, the importance of which can hardly be overestimated.

With increasing control of communicable diseases and infant mortality, inherited abnormalities are assuming a proportionately greater importance is medical practice. Over 2,300 hereditary diseases have been identified and more are added to the list every year. According to many authors, genetically conditioned diseases or diseases with a clear genetic component account for 25–40 per cent of all cases treated by the health services.

Human genetics is much more than the study of mere hereditary disease. It has emerged as a basic biological science for understanding the endogenous factors in health and disease and the complex interaction between nature and nurture. Owing to rapid specialization, several branches in genetics have come into being, e.g., cytogenetics, biochemical genetics, clinical genetics, pharmacogenetics, immunogenetics, microbial genetics, population genetics and so on. Achievements in these fields have created a basis for effective medical and preventive intervention in many diseases, and also possibly of "genetic engineering", i.e., of controlling the traits of an individual.

Cytologic facts

In 1956 Tito and Levian surprised the scientific world by reporting that they could find only 46 chromosomes in the normal human karyotype. This was immediately confirmed by other workers. There is now universal agreement that the normal human body cell (except the sex cells) contains 46 chromosomes, i.e., 22 pairs of autosomes and a pair of sex chromosomes, XX in the female and XY in the male. The chromosomes vary in length, the longest being about 3 times as long as the smallest. Each pair of chromosomes is homologous. The autosomes are numbered according to their length, the first pair being the longest and the last pair the shortest. The sex chromosomes are not included in the numbering, but are merely termed X and Y. Barr and his group discovered that the normal female cell nucleus contains in addition a dark-staining area at the periphery of cell nucleus, called a Barr body or "sex chromosome" body which is not present in normal males.

The autosomes have been classified and divided on the basis of length and certain morphological similarities into 7 groups as follows:

- Group A ..... 1 to 3 pairs
- Group B ..... 4 to 5 pairs
- Group C ..... 6 to 12 pairs
- Group D ..... 13 to 15 pairs
- Group E ..... 16 to 18 pairs
- Group F ..... 19 and 20 pairs
- Group G ..... 21 and 22 pairs

The X-chromosome is included in Group "C" with chromosomes 6–12, and the Y-chromosome is included in Group G with chromosomes 21 and 22.

Mitosis

During ordinary cell division, each chromosome divides lengthwise into two sister chromosomes called chromatids. The chromatids are joined together for a short time at a point called centromere. Then the chromatids separate, one goes to one daughter cell and one to the other daughter cell. In this manner, each daughter cell inherits the same number and kind of sister chromosomes. This process of nuclear division is called mitosis.

Meiosis

The reproductive cells (sperms and eggs) are produced in a different manner. There are two nuclear divisions and only one chromosome division. This form of division is called 'reduction division' or meiosis. A detailed description of meiosis is unnecessary here. Broadly, the main events in meiosis are:

1. The homologous chromosomes first come together. This is called "pairing".
2. The chromosomes then replicate — each dividing into two chromatids which are held together at centromere.
3. At this stage there is "crossing over" and a redistribution of genetic material.
4. Then the homologous chromosomes separate — one goes to one pole of the nucleus and the other to the other pole.

The chromosome number is thus reduced to half, i.e., 23.

5. The cell divides and the nucleus of each daughter cell contains 23 chromosomes.

6. The second meiotic division follows: the centromeres divide and the chromatids move apart. (7) The cell divides again so that the daughter cells each contain 23 chromosomes. During fertilization, the two half-sets come together and restore the full complement of 46. The full complement of 46 chromosomes is called the diploid number, and the half set of 23 is called the haploid number.

Chromosomes

Chromosomes are rod-like condensations of chromatin. They become visible in the nucleus only during cell division. They occur in pairs — one member of each pair comes from
the father, and other from the mother. The largest chromosome measures about 7 μ m is about five times the length of another. Biochemically, the chromosomes are made up of deoxyribonucleic acid (DNA). Genetically, they consist of genes arranged like the beads of a necklace. The number of chromosomes in each species is fixed. All individuals of the same species have the same number of chromosomes (with exceptions). Thus the total number for man is 46, for the fruit fly 8, for Drosophila melanogaster 14 and potato 63.

Methods of Chromosomal Study: Buccal smears, peripheral blood, bone marrow, skin and in some instances testis tissue are used to study chromosomes. More information can be obtained by using cell cultures. Cells, which are usually peripheral white blood cells, are cultured in the proper medium and incubated for 3 days. Colchicine is then added to arrest cells in metaphase. After further incubation for 3 to 5 hours, the cells are placed in a hypotonic solution which causes them to swell and the chromosomes to disperse within the cell. The cells are fixed, stained and examined for chromosomes. A more recent discovery in cytogenetics is the fluorescent staining of chromosomes. It has been shown that human chromosomes treated with quinacrine hydrochloride (Atabrine) or quinacrine mustard exhibit distinct fluorescence (2).

Genes

Genes are the units of heredity. They contain the hereditary information encoded in their chemical structure for transmission from generation to generation. They affect development and function, both normal and abnormal. The number of genes in each species is fixed. All chromosomes are about them by indirect methods. It is said we inherit about 50,000 genes from the father and 50,000 from the mother. The number of chromosomes is fixed and unique to each species. For example, the locus for the ABO blood group system is in chromosome 9 and the locus for the major histocompatibility complex is in chromosome 6. The Y-chromosome contains genes that determine the normal development of testes. It is known that the human X-chromosome carries the genes governing a blood group haemophilia, red-green colour-blindness, glucose-6-phosphate dehydrogenase, muscular dystrophy, height and gonadal development (3). Presumably, some thousands of loci are contained in chromosomes. More than 20 loci have been assigned to chromosome 1 including the Rh locus. More than 100 loci have been assigned to X-chromosome (4).

Since genes are contained in the chromosomes, genes also occur in pairs. If the genes comprising a pair are alike (AA), the individual is described as homozygous for that gene, and if it is different (Aa) the individual is described as heterozygous.

A gene is said to be dominant when it manifests its effect both in the heterozygous and the homoygous state. A gene is said to be recessive when it manifests its effect only in the homozygous state. Genes whose combined action affects one particular character are known as polygenes or "multiple genes". In man three genes have been identified as being responsible for muscular dystrophy: one is a sex-linked recessive gene, the second is an autosomal recessive, and the third is an autosomal dominant gene. Many instances are known in which the same character is controlled by several genes – the colour of our skin, height and weight, life span, degree of resistance to disease, rate of heart beat, arterial blood pressure and many other inherited traits. These genes may occupy separate positions in the chromosomes; some may be widely distributed on several non-homologous chromosomes (3). The extent to which a chemical constitution of the cell is determined by a single chromosome, or whether the individual is a carrier for a lethal allele, remains a subject of research.

Genotype and phenotype

The term genotype refers to the total genetic constitution of an individual and the term phenotype to the outward expression of the genetic constitution. Taking the ABO blood group system, the possible genotypes are AA, AB, BB, AO, BO, but the phenotypes are A, B, AB, O. The form, size and structure of genes are all phenotypical expressions of a particular genetic constitution. Certain phenotype characteristics of an individual may change from infancy to adulthood such as height, weight, musculature, body shape, but the genotype is relatively stable throughout the life of an individual. Thus there are two aspects of the genetic material – one fixed and the other plastic. The fixed characters are the genotype, and the plastic ones are the phenotype. These two types may best be compared to a given pelican of clay which may be moulded into any desired shape by an artist but the weight, volume, density and bulk remain the same (6). Therefore, it is said that medicine is the science of management of the human phenotype (7).

Chromosomal abnormalities

Chromosomal abnormalities (numerical or structural alterations) occur from time to time in human beings. They arise in various ways: (1) Non-disjunction: By an error in nuclear division called "non-disjunction" a pair of chromosomes may fail to separate and both are carried to one pole. The resulting daughter cells contain an unequal number of chromosomes, 45 or 47. This numerical abnormality in which the chromosome number is not an exact multiple of the haploid number is called aneuploidy. If a particular pair of chromosomes has three chromosomes instead of two, it is called "trisomy"; if there is only one chromosome instead of two in any given pair of chromosomes, it is called "monosomy". Non-disjunction may occur during gametogenesis or during mitosis. (2) Translocation: Sometimes during nuclear division, a portion of one chromosome breaks away and becomes attached to another which is not homologous to the first. This is called translocation. (3) Deletion: A piece of a chromosome may become detached and lost from the karyotype resulting in the loss of one or more genes. If the loss is severe, it may be incompatible with life. (4) Duplication: Some genes may appear twice in the same chromosome. This is called duplication. (5) Inversion: Sometimes a chromosome segment becomes inverted and the order of sequence of genes is altered. (6) Isochromosomes: These are a special class of structurally abnormal chromosomes, arising because of misdivision, i.e., transverse division instead of the normal longitudinal division. (7) Mosaicism: The cells of the body are composed of cells of two or more genetically different
chromosomal types. This can result by mutation or non-
disjunction either during embryo or later life.

**Laws of inheritance**

Mendel crossed two races of the common pea (Pisum sativum) a tall and a short. The first generation (F₁ generation) consisted entirely of tall offspring. But when the F₁ generation was inbred, they gave rise to a mixed generation of tall and short in the ratio of 3:1, i.e., three-fourth tall and one-fourth short. This generation is known as the F₂ generation or the second filial generation. All the short plants of the F₂ generation bred true, producing short plants only. But the tall plants of the F₂ generation gave rise to a mixture of tall and short offspring in the same ratio of 3:1. The F₂ generation is therefore 1:2:1, i.e., one-fourth pure tall, half mixed tall and one-fourth pure short. From the result of his experiments, Mendel formulated certain laws to explain the inheritance of characters: (1) Law of unit characters: All characters are units by themselves, and certain factors (now called genes) control the expression of these characters during the development of the organism. (2) Law of dominance: The factors or genes occur in pairs. One factor may mask the expression of the other. The character that expresses itself in the F₁ generation is said to be dominant, and the character that does not appear in the F₁ generation is said to be recessive. (3) Law of segregation: When germ cells are formed, Mendel supposed, that the opposed factors are separated or segregated so that each germ cell carries one or other of the two factors and not both. Mendel’s work provided the basis of the study of inheritance.

**Classification of genetic disorders**

These may be classified as:

a. Chromosomal abnormalities
b. Unifactorial (single gene or Mendelian) diseases
c. Multifactorial disorders

**CHROMOSOMAL DISORDERS**

More than 300 numerical and structural types of chromosome aberrations have been described. A significant portion of embryonic and foetal wastage is due to chromosomal anomalies. The incidence of chromosomal abnormalities is 5.6 per 1000 live births. Of these, 2 per 1000 live births represent sex abnormalities, 1.7 per 1000 live births autosomal aneuploidies, and 1.9 per 1000 live births chromosomal translocations. For the most part, these disorders are not inherited (4).

1. **Relating to sex chromosomes**

The following are some of the well-known syndromes associated with abnormalities of sex chromosomes:

(a) **Klinefelter’s syndrome**: This is a common sex - chromosome aneuploidy. Persons suffering from this syndrome are abnormal males having two or more X-chromosomes in addition to one Y-chromosome (XXX, XXXY, XXXY, XYYY, etc.). They have a normal autosomal set of 46. The main features of this syndrome are that the affected persons are eunuchoid males with non-functional testes. Spermatozoa are absent in their ejaculations. The growth of hair on face, axillae and pubis is scanty. The condition is associated with gynaecomastia and mental retardation. The incidence of this syndrome is about 1 in 1000 males at birth (9).

(b) **XYY syndrome**: The male with an extra Y-chromosome has attracted much attention because of his reported tendency to anti-social, aggressive and often criminal behaviour. However, the relationship is not yet clear. The principal features of this syndrome appear to be exceptional height (usually six feet and over) and a serious personality disorder leading to behavioural disturbances (10). The incidence of this syndrome is about 1 in 1000 males at birth (9).

(c) **Turner’s syndrome**: This anomaly is probably the most common inborn error of metabolism, but about 98 per cent of the conceptuses abort spontaneously. The remaining 2 per cent that reach term, account for about 8 per cent of all female stillbirths. They have an increased risk of dying in the neonatal period. Persons suffering from this syndrome are apparent females with underdeveloped sex glands. They have 45 chromosomes instead of the normal complement of 46. Their sex chromosome constitution is XO instead of XX (19). Turner’s syndrome (gonadal dysgenesis syndrome): his abnormal condition is due to non-disjunction of the sex chromosomes. Clinically the patients are of short stature, infertile and have primary amenorrhea. They often show other congenital defects such as coarctation of the aorta, pulmonary stenosis, renal malformation and mental retardation.

(d) **“Super females”**: Females with 3 to 5 X-chromosomes (XXX, XXXX, XXXXX) have been found. In general, the higher the number of X-chromosomes, the greater the degree of mental retardation and congenital abnormalities, e.g., underdeveloped external genitalia, uterus and vagina.

2. **Relating to autosomes**

There are many syndromes associated with abnormalities of autosomes. A full description of these conditions is beyond the scope of this book. A brief account of mongolism which is a public health problem in some countries is given here. Mongolism or Down’s Syndrome was described by Langdon Down in 1866. Most cases of mongolism are caused by an extra chromosome which occurs on the 21st pair. The anomaly is therefore sometimes described as “Trisomy 21”. The syndrome is only recognized in the older child and adult by the short stature and small round head, narrow, tilted eye-silts, mal-formed ears, short broad hands, lax limbs, mental retardation and quite a few other abnormalities especially internal congenital defects such as cardiac defects and atresia of the alimentary tract. In communities of European origin the incidence of mongolism at birth is reported to be one in 900 births (9).

One observation which is important is that the frequency of mongolism increases with rising maternal age but is un-affected by the age of the father. The risk for a woman of 20 is estimated at about 1 in 3,000 and that for a woman of 45, 1 in 50 (11).

Autosomal monosomies are rare. Loss of an entire chromosome can be very serious genetic defect; the fertilized ovum may not survive.

**MENDELIAN DISEASES**

Mendelian diseases are inherited according to the Mendelian Laws. There are the dominant, recessive and sex-linked diseases. (a) An individual with an autosomal dominant trait will produce two kinds of gametes with respect to the mutant gene—half with the mutant gene and half with the normal allele. The offspring of such an
individual has a 50:50 chance of being affected, provided the other parent is normal. The sexes are equally affected.

(b) Abnormalities caused by recessive genes occur when both the parents are heterozygous. Each offspring of such parents has a chance of 1/4 being affected. Autosomal recessive diseases occur sporadically in the children of widely normal parents. (c) In sex linked inheritance, a mutant gene on X-chromosome in males will express itself readily as there is no normal allele, while a mutant gene on X-chromosome in females will not express itself in the presence of the normal allele. This is the basis of sex-linked inheritance of which haemophilia is an outstanding example. If an affected male marries a normal female, the gene is transmitted to all the daughters, but the sons escape. But if a carrier female marries a normal male, 50 per cent of her daughters will be carriers and 50 per cent normal; 50 per cent of her sons will be affected and 50 per cent normal. Fig.1 shows the patterns of inheritance.

Mendelian diseases are individually rare since there is strong selection against them and gene mutations are rare events. Mutation usually occurs at random. If mutation is confined to a single gene it is called "point" mutation, which is responsible for many human diseases and defects.

It is estimated that the combined incidence in man of diseases and disabilities in this category is about 1 per cent of all live-born individuals (12). Rare as these diseases are, as many as 793 autosomal dominant phenotypes, 659 autosomal recessive traits and 123 sex-linked diseases have been catalogued to date (10). A short list of these abnormalities is given in Table 1.

**Blood groups**

Early genetic studies centred around blood groups in man. Blood groups are determined by genes. At present 14 blood group systems have been discovered in man; the well-known ones are the ABO and Rh blood groups.

Source: (5)

Gene O is recessive; the red blood cells of a person whose blood group is O have no antigens. Genes A and B are co-dominant; when both are present, the red blood cells carry antigen-A and antigen-B. Blood groups provide valuable evidence in cases where there is a question of true parentage; they are also extensively used to determine whether the twins are identical or not.
RHEUS SYSTEM

The Rhesus system depends upon three genes which are designated by the letters C, D and E and their alleles by the small letters c, d and e. The Rh-antigens develop very early and have been demonstrated in a 38-day old foetus. It had been established that the Rh-antigens are present only on the surface of red cells (14).

The possible genotypes in the rhesus system will be CDE, CDe, cDE, cDE and cDE. The diploid individual inherits any two of these units, e.g., CDe/cDe. Of the rhesus antigens, the most potent is the antigen D; so much so, the term "Rhesus-positive" has come to mean possessing this antigen and the "Rh-negative" lacking it. In India, it is found that about 93 per cent of the population are Rhesus-positive as compared to 85 per cent in countries of Northern Europe and North America (12). The importance of the rhesus system in preventive medicine is exemplified in the fatal disease in the newborn, Erythroblastosis foetalis.

Erythroblastosis foetalis

If the foetus is Rh-positive and the mother Rh-negative, certain consequences are likely. Some of the foetal red cells cross the placenta and enter the maternal circulation where they act as foreign antigens and the production of Rh antibodies.

The Rh antibodies are of two main types: (a) the "strong" or saline antibodies and (b) the "weak" or albumin antibodies. The latter are small 75 gamma globulins which cross the placental barrier and pass back into the blood circulation of the foetus. When this happens, the RBC of the foetus are destroyed. If the damage is severe, the foetus is killed. With less severe damage, the infant may be born with jaundice, anaemia and oedema. This symptom complex is known as Rh-haemolytic disease or erythroblastosis foetalis.

Blood groups and disease

During the past 10 years researchers have been trying to find out the association of certain diseases with particular blood groups. However, only two disease conditions have shown such association with the ABO groups. Duodenal ulcer and gastric ulcer are common in 'O' group and stomach cancer in 'K' group individuals. A number of other diseases appear to be associated with particular blood groups, especially carcinoma of the uterine cervix and periodontal anaemia with group 'A', and rheumatic heart disease with a lack of group 'O'. Haemolytic tendencies appear to be associated with group 'O', and thrombosis with group 'K'. An 'A' group woman taking oral contraceptives is at greater risk of thrombotic episodes than an 'O' group woman (15). The demonstration of associations between blood groups and certain diseases is an important contribution of human genetics.

Sickle cell anaemia

Sickle cell anaemia is an autosomal recessive disorder in which an abnormal haemoglobin leads to chronic haemolytic anaemia with a variety of severe clinical consequences. The disorder is a classic example of disease caused by a point mutation in DNA. Individuals with one gene of this disease are clinically healthy, but their RBC look abnormal under the microscope. Persons with 2 genes (homozygous) of this disease suffer from acute anaemia and in most cases die before puberty. The rate of sickling is influenced by a number of factors, most importantly by concentration of haemoglobin S in the individual red blood cell.

The disease is prevalent among blacks, specially in certain parts of Africa. It has been found that in areas where the disease is most prevalent also showed the higher frequencies of malaria. The haemoglobin S gene is carried in 8 per cent of American blacks. The haemoglobin S in American blacks will produce a child with sickle cell anaemia. In India, it is an important disorder on account of its high incidence in certain areas.

The disorder has its onset during the first year of life, when haemoglobin F level falls. These patients are prone to thrombosis, which are used to. Examination by point mutations are chronic in different areas. They are hepatomaculopigmentary, but the spleen is not palpable in adult life. The heart is enlarged, with histological changes of fatty and pseudo-amyloid heart. Healing ulcers may be present. Sickle cell anaemia becomes a chronic multisystem disease, with death from organ failure complications. No specific treatment is available. However, both longevity and quality of life may be improved by comprehensive medical management. Prenatal diagnosis is now available for couples at risk of producing a child with sickle cell anaemia. DNA from fetal cells can be directly examined, and the presence of the sickle cell mutation can be accurately diagnosed. Genetic counselling should be made available to such couples (9).

Thalassaemias

The thalassaemias are hereditary disorders characterized by reduction in the synthesis of globin chain (alpha or beta). Reduced synthesis of globin chain causes reduced haemoglobin synthesis and eventually produces a hypochromic microcytic anaemia because of defective haemoglobinization of red cells. Thalassaemias can be considered among hypo-proliferative anaemias, the haemolytic anaemias, and the anaemias related to abnormal haemoglobin, since all of these factors may play a role.

Alpha thalassaemia is primarily due to gene deletion directly causing reduced a globin chain synthesis. Beta thalassaemia is caused by point mutations rather than large deletions. Signs of thalassaemia develop after 6 months of age, because this is the time when haemoglobin synthesis switches from production of alpha chains to production of beta chains. Prenatal diagnosis is available for couples at risk of producing a child with one of the severe thalassaemia syndromes. Asian couples whose parents are carriers on both sides have alpha thalassaemia trait are at risk of producing an infant with hydrops foetalis. Mediterranean people with both parents heterozygous for beta thalassaemia, are at risk of producing homozygous child (9).

Haemophilia (16)

Haemophilia is a hereditary bleeding disorder affecting 15-20 of every 100,000 males born, with equal incidence in all ethnic groups and geographical areas that have been surveyed. Prevalence, which depends on survival, varies according to available medical care. There are an estimated 420,000 people with haemophilia worldwide.

There are different forms of haemophilia. While the disorder affects males, it is carried by females, who are only occasionally affected, usually mildly. The disorder concerns the absence, decrease or deficient function of blood coagulating factor, leading to excessive, prolonged or
delayed bleeding. In severe cases it most commonly occurs in the large joints of the limbs. Unless such bleeding is controlled promptly by infusion of the deficient factor, there is progressive joint disease and muscle atrophy, leading to serious physical, psychological and social handicaps. Until recently, the foremost cause of death was haemorrhage, especially in the skull.

In countries with highly developed haemophilia care programmes, therapy with plasma derivatives has reduced mortality. In the past decade, the main causes of death have stemmed from infections as the side-effects of treatment, including AIDS and liver disease secondary to hepatitis. Survivors in patients without these infections is almost the same as that of the general population.

Cystic fibrosis (16)

Cystic fibrosis is a genetic disease occurring worldwide, which affects the respiratory and gastrointestinal tracts and the sweat glands. Incidence ranges from 2.5 to 5 per 10,000 live births in most European populations. The condition is less common in blacks, and rare in orientals.

Until a few years ago, life expectancy of children with the disease was below 5 years of age. Now that it is recognized and treated earlier and more effectively, life expectancy in developed countries is about 30 years, and projections for young children alive with cystic fibrosis now suggest that they may live for 40 years or more, even without the development of new treatments. However, upto 95% of cases in Latin America are never diagnosed, and the life expectancy of those that are diagnosed is only about 10 years.

The gene defect in cystic fibrosis was identified in 1989, since then there has been unprecedented progress in understanding the disease, leading to new approaches to drug treatment and hopes for gene therapy. Such treatments are expected to be available within the lifetime of most current patients, with a corresponding anticipated improvement in outlook.

Phenylketonuria (PKU)

Phenylketonuria is an autosomal recessive disorder resulting in a deficiency of the liver enzyme phenylalanine hydroxylase which converts phenylalanine to tyrosine. The name PKU is derived from the build-up of phenylpyruvic acid in the urine, a characteristic of the disease. The frequency of the disease is about 1 in 10,000 births (5).

Phenylalanine accumulates in the blood and tissues and has toxic effect on the brain leading to mental retardation. Tests for elevated blood levels of phenylalanine are much more desirable than tests for urine phenylketone, since blood levels must be elevated before urine detection is possible. Testing of bottle-fed infants should be done no sooner than 48 hours after the first successful formula feeding. Breast-fed babies, however, are tested at 7 days, since breast milk often has little protein content before the 5th day (17).

MULTIFACTORIAL DISORDERS

The frequency of multifactorial disorders is high compared with that of Mendelian and chromosomal disorders. There are indications that most of the common disorders of adult life such as essential hypertension, schizophrenia, mental retardation, duodenal ulcer, ischaemic heart disease of early onset, diabetes, congenital heart malformations are conditions with a multifactorial aetiology. A small minority of cancers (family cancer syndromes) are clearly inherited; these include familial polyposis coli, familial non-polyposis colon cancer and some thyroid cancers. Also known is a major genetic component in cancers of the colon and breast, although in these relatively common conditions it can be difficult to distinguish familial from non-familial cases.

In a disorder such as cancer or coronary heart disease, features that should arouse suspicion of an inherited predisposition include: early onset; similarly affected parents and/or siblings; when there is a difference in frequency between the sexes, occurrence in the less commonly affected sex (e.g., coronary heart disease in women); in ethnic groups in which there is a high incidence of a particular condition (e.g., spina bifida is 40 times more common in Caucasians - and even more frequent among the Irish - than in Asians).

The mode of inheritance of multifactorial disorders is complex because environmental factors are also involved, as for instance, the influence of smoking, diet, obesity and lack of exercise on ischaemic heart disease. Campbell (1965) stressed that environmental agents and genetic constitutions usually interact closely in producing abnormalities. He summarizes his conclusions in saying that some genetic factors are effective only under certain environmental conditions (17). The relative contributions of genetic predisposition and environmental factors to the aetiology will vary greatly from patient to patient.

Role of genetic predisposition in common disorders (16)

Although the limits of intelligence, physical ability and longevity are genetically determined, external and environmental influences such as infections, malnutrition and war have long been the main determinants of health and survival. Now, with increased control of the environment, genetic make-up is becoming an ever more important determinant of individual health. Genetic predisposition may lead to the premature onset of common diseases of adult life such as cancer, coronary heart disease, diabetes, hypertension and mental disorders.

Cancer: It is not yet certain whether most cancers are hereditary. But a genetic predisposition may be involved in as many as 10-25% of cases of cancer of the breast or colon. Numerous genes are being identified that may affect susceptibility to tumour development. This may lead to a general improvement in the diagnosis and treatment of cancer. For example, a DNA screening test for breast cancer could soon be available. Advice could be offered on the prevention of cancers, tailored for families with different types of cancer risk.

Coronary heart disease: Until recently, it was generally believed that environmental factors alone cause coronary heart disease. But investigating family histories often uncover genetic risks. Mapping the human genome will make the genetic predisposition to CHD much easier. High blood pressure and high blood cholesterol levels, major risk factors in CHD, are also genetically influenced. A combination of risk detection and lifestyle counselling, with drug treatment, might cut the incidence of heart attacks to the low levels as two or three generations ago.

Diabetes: Evidence for a genetic element in insulin-dependent diabetes mellitus has emerged from studies.
showing a higher concordance in identical twins (25-30%) than in non-identical twins (5-10%). About 85% of cases of diabetes in developed countries are of the non-insulin-dependent form of the disease, which has a particularly strong familial tendency. Diabetes of all types is an important candidate for future treatments such as gene therapy of pancreatic tissue transplantation.

Mental disorders: Evidence from family and twin studies demonstrate the existence of genetic predisposition to some common mental diseases. Alzheimer's disease, the most common form of senile dementia, has a strong familial tendency and is known to be caused by at least four different genes. Research may lead to the development of drugs useful in preventing or delaying the onset of the disease.

Enough is already known about the genetics of common diseases to introduce a family-oriented approach into basic as well as specialist medical practice. A major effort is being made to study the genetic factors involved, develop appropriate therapies, and determine how these approaches can best be applied in practice.

Advances in molecular genetics (5)

DNA technology depends on a number of basic tools that have been gradually developed over the past 20 years or so. A wide range of enzymes involved in DNA and RNA synthesis and repair have been identified and become available for laboratory use, nucleotide bases are available as laboratory reagents, and specific DNA sequences can be synthesized at will. DNA diagnostic methods have been greatly simplified over the past 10 years. DNA has many advantages for genetic diagnosis. It is easy to obtain, since every cell of an individual or fetus contains the full DNA complement of that individual. Genes can be studied whether they are actively producing their product or not. A definitive diagnosis can usually be made in all genetic conditions.

1. DNA technology (5)

Major new techniques that are contributing to the advances in medical genetics include the following:

- The synthesis of DNA probes with specific sequences that will bind to and identify any complementary DNA sequences that may be present. This allows genetic diagnosis and permits further analysis of DNA by the examination of unknown sequences adjacent to the known ones.

- DNA sequencing methods for the rapid analysis of unknown DNA and the identification of mutations that give rise to disease.

- New diagnostic techniques, such as the use of restriction enzymes that cut DNA consistently only at specific sequences, and the polymerase chain reaction (PCR) for amplifying known DNA sequences. Such methods allow simple and rapid diagnosis using extremely small tissue samples. It is even becoming possible to analyse the DNA contained in a single cell.

- Techniques for synthesis of DNA that allow the production of known sequences of increasing length. Coding sequences produced in this way can be used for the production of therapeutic agents such as insulin, erythropoietic and factor VIII. They may also be used in the creation of transgenic animals and in gene therapy.

- Positional cloning strategies using genetic markers, which are now defined along the entire human genome. These have greatly simplified the study of families. Even quite small kindreds can be examined using highly informative probes, and disease mutations can be rapidly assigned to their chromosomal position.

- In vitro methods for examining the protein product of gene sequences with unknown functions.

- New recombiant techniques such as fluorescence in situ hybridization (FISH), which permits direct visualization of the relationship of genes to one that function in the nucleus of the living cell.

- Comparison between the DNA sequences of different genes and species. This helps elucidate the mechanisms of evolution.

- Insertion of coding DNA sequences into animal embryos to create transgenic animals, including animal models of human diseases. The availability of transgenic techniques and the use of experimental site-specific mutagenesis are particularly valuable for studying the roles of specific genes in multifactorial diseases, where combinations of different genotypes and environments can be examined.

- Insertion of missing DNA sequences into individuals with genetically determined disorders, or the excision of harmful sequences (gene therapy).

2. Gene therapy (5)

Gene therapy is the introduction of a gene sequence into a cell with the aim of modifying the cell's behaviour in a clinically relevant fashion. It may be used in several ways, e.g., to correct a genetic mutation (as for cystic fibrosis), to kill a cell (as for cancer) or to modify susceptibility (as for coronary artery disease).

The gene may be introduced using a virus (usually a retrovirus or adenovirus) or by means of lipid or receptor targeting. There is now almost universal agreement that gene delivery to somatic cell to treat disease is ethical, and disease, may take its place alongside other forms of medical treatment.

3. The human genome project (5)

The human genome project is an attempt to systematize the research on mapping and isolating human genes that is already in progress in many countries, in order to create a single linear map of the human genome, with each coding gene defined and sequenced.

Agencies with a role in coordinating human genome data include UNESCO, the Genome Data Base, HUGO, the National Institute of Health/Department of Energy (USA), the Medical Research Council (UK), Genethon (France) and the European Union.

4. The human genome diversity project (5)

As part of the work of HUGO, the Human Genome Diversity Project is aimed at increasing understanding of human evolution. The major objective is to define the genetic relationships between human populations and interpret them in terms of natural selection, genetic drift, migration, etc. For example, the frequency and distribution of rare single-gene disorders are related to the history of human migration. Differences in distribution between
MULTIFACTORIAL DISORDERS

populations may often be accounted for by "founder effects." When a population expands from a relatively few founding members, some contribute more, and some less, to the genetic make-up of subsequent generations. If one prolific founder carries a genetic abnormality, this can lead to a localized cluster of affected individuals. Studies of isolated and aboriginal populations can be particularly informative.

Population genetics

Population genetics has been defined as the study of the precise genetic composition of population and various factors determining the incidence of inherited traits in them (10).

Population genetics is founded on a principle enunciated independently by Hardy & England and Weinberg in Germany in 1908. Let us consider the results when a human population consisting of tall (TT), intermediate (Tt) and short (tt) individuals were allowed to mate at random. Even after several generations of interbreeding, it will be found that there will be some individuals who are tall (TT) some intermediate (Tt) and some short (tt). In other words, we cannot produce a race which is "pure" or uniform in height.

The Hardy-Weinberg law states that the "relative frequencies of each gene allele tend to remain constant from generation to generation" in the absence of forces that change the gene frequencies. Thus, the study of gene frequencies, and the influences which operate to alter the "gene pool" and their long-term consequences is the central theme in population genetics.

Factors which influence the gene frequencies

The Hardy-Weinberg law assumes that human population is static. But in reality, human population and consequently human gene pool is never static. There are several factors which influence the human gene pool. The following are some:
(a) Mutation - Mutation implies a change in the genetic material of an organism which results in a new inherited variation. Mutation is a rather rare phenomenon in nature. It is now recognized that mutant genes are so wide-spread in their occurrence that every one of us might be harbouring a few or many of them. According to modern geneticists, the entire body structure of man and every animal and plant cell have been built through hundreds of millions of years by means of a long succession of mutation (7). The cause of spontaneous mutation is not yet known. But we know that certain external influences such as ionizing radiation and certain chemicals are capable of producing mutations experimentally and there is no reason to believe that man is an exception. Most mutant genes are believed to be harmful. But there are instances where a mutant gene could be beneficial, e.g., sickle cell anaemia. The heterozygotes of sickle cell trait were found to be resistant to falciparum malaria. Some mutant genes remain "neutral" in that they do not harm or impair the survival ability of the organism. Such genes may persist indefinitely in the population for many generations. Specialists in population genetics are interested in mutation rates. It is said that each gene has its own characteristic mutation rate which is estimated anywhere from 10⁻⁶ to 10⁻⁸ per generation. During the past 30 years, mutation rates have probably risen owing to increased use of X-rays and chemical mutagens.
(b) Natural selection - Darwin proposed the theory of natural selection or survival of the fittest to explain evolution. Natural selection is the process whereby harmful genes are eliminated or kept from the gene pool and genes favourable to an individual tend to be preserved and passed on to the offspring. When DDT was first used, it was lethal to mosquitoes but not to houseflies. However, houseflies do not apply in human populations because man by his superior intelligence has interfered with natural selection in every conceivable way; by changing the environmental conditions under which people live and by advances in technology, public health and medical care services. The forces that work in the opposite direction are, increased facilities for earning, ways of living and education, people are moving; sometimes on a large scale - from rural to urban areas. There is also a migration of people between countries. Such population movements will lead to changes in the distribution of genes, affecting both the areas of immigration and emigration. The intermixing of people makes new genetic combinations possible. (d) Breeding structure - if all marriages were to occur in a random fashion, the effect would be the attainment of a genetic equilibrium. In practice, however, marriages tend to occur selectively within various subgroups based on religion, economic and educational status and family relationships. In open societies, there is more freedom in mating. For instance doctors tend to marry doctors or nurses; musicians tend to marry musicians. This type of mating is called "assortative mating," or birds of the same feather flocking together. The genetic consequences of assortative mating have not been adequately studied. (e) Public health measures - health and medical care services do affect the genetic endowment of people as a whole. More laws are now being saved by advances in medicine than ever before. For instance, Rubella vaccination operation which was introduced in 1912 has saved many children suffering from congenital pyloric stenosis. Interventions with genetic material in the human body can be saved by timely surgery. The provision of insulin has saved the lives of diabetics. The carriers of hereditary diseases, such as cystic fibrosis, are now able to survive and pass their genes to their progeny. Public health measures are thus decreasing the selection rates and ameliorating the genetic burden. This has led some scientists to prophesy that "medicine will harm people in the long run by helping them in the short run" (12).

PREVENTIVE AND SOCIAL MEASURES

1. Health promotional measures

(a) Eugenics - Galton proposed the term eugenics for the science which aims to improve the genetic endowment of human population. Eugenics has both negative and positive aspects.
(b) Negative eugenics - Hitler sought to improve the German race by killing the weak and defective; this was negative eugenics. But nobody in the civilized world would approve of such a measure to improve the human race.

On the other hand, if people who are suffering from serious hereditary diseases are sterilized or otherwise debarred from producing children, there should be no
 Serious objection to marriage. The aim of negative eugenics is to reduce the frequency of hereditary disease and disability in the community to as low as possible. However, the question one would ask is how far negative eugenic measures would be helpful in eliminating genetic defects? The simple answer is that it is quite of eugenic sterilisation, new cases of hereditary diseases will continue to arise in the population partly because of fresh mutations, and partly because of marriages between carriers (heterozygotes) of recessive defects. Nevertheless, it may be hoped that should eugenic measures be applied, hereditary diseases would become less frequent (12).

(ii) Positive eugenics: This is a more ambitious programme than negative eugenics. It seeks to improve the genetic composition of the population by encouraging the carriers of desirable genotypes to assume the burden of parenthood. At present, positive eugenics has very little application. Its realisation is difficult for 2 reasons: (i) The majority of socially valuable traits — let us say — intelligence and positive character features, though partially determined biologically are not inherited in such a simple way as, say, blood groups. These traits have a complex, multifactorial determination, both genetic and environmental. It would be difficult to expect, therefore, that positive eugenic measures will yield direct results (ii) Secondly, we cannot determine which gene we transmit to our children (7).

(b) EUTHENICS: More improvement of the genotype is of no use unless the improved genotype is given access to a suitable environment, an environment which will enable the genes to express themselves readily. Throughout the course of history, man has been adapting environment to his genes more than adapting his genes to the environment. Studies with mentally retarded (mild) children indicated that exposing them to environmental stimulation improved their IQ. Thus the solution of improving the human race does not lie in constraining heredity and environment, but rather in the mutual interaction of heredity and environmental factors. This environmental manipulation is called eugenics and has considerable breeder prospects for success.

(c) GENETIC COUNSELLING (19): The most important and practical service that genetics can render to medicine and surgery is genetic counselling (12). Genetic counselling may be prospective or retrospective (8).

(i) Prospective genetic counselling: This allows for the true prevention of disease. This approach requires identifying heterozygous individuals for any particular defect by screening procedures and explaining to them the risk of their having affected children if they marry another heterozygote for the same gene. In other words, if heterozygous marriage can be prevented or reduced, the prospects of giving birth to affected children will diminish. The application in this field, for example, are sickle cell anaemia and thalassemia. It is possible that this kind of prevention may find wider application to cover a number of other conditions. More information and medical services are indicated.

(ii) Retrospective genetic counselling: Most genetic counselling is at present retrospective, i.e., the hereditary disorder has already occurred within the family. A survey carried out by the WHO showed that genetic advice was chiefly sought in connection with congenital abnormalities, mental retardation, psychiatric illness and inborn errors of metabolism and only a few sought premarital advice. The WHO recommends the establishment of genetic counselling centres in sufficient numbers in regions where infectious disease and nutritional disorders have been brought under control and in areas where genetic disorders have always constituted a serious public health problem (e.g., sickle cell anaemia and thalassemia) (12).

The methods which might be suggested under retrospective genetic counselling are: (i) contraception (ii) pregnancy termination and (iii) sterilisation depending upon the attitudes and cultural environment of the couples involved (8).

(d) OTHER GENETIC PREVENTIVE MEASURES: (i) Counselling may show that in each carrier there is an increased risk in the offspring of traits controlled by recessive genes, and those determined by polygenes. Examples are albinism, alkaptonuria, phenylketonuria and several others. An increased risk of premature death is also noted in such offspring. For instance, in a certain Japanese city, a death rate of 116 per 1,000 was found during the first 8 years of life amongst the offspring of first cousins, against 55 amongst the controls (12). Therefore, a lowering of consanguineous marriages would be advantageous to the health of the community.

(iii) Late marriages: The pendulum is swinging in favour of late marriages. The discovery of "Tinman 21" in mongols coupled with the knowledge that mongolism is more frequent in children born of elderly mothers, lends support to the view that early marriage of females is better than late marriage from the point of view of preventing mongolism. Its incidence in a mother at age 20 is only : 3000, by the age 40, its 1:40.

2. Specific protection

Increasing attention is now being paid to the protection of individuals and whole communities against mutations such as X-rays and other ionizing radiations and also chemical mutagens. Patients undergoing X-ray examination should be protected against unnecessary exposure of the gonads to radiation. X-ray examination of the pregnant uterus to determine the presence of twins or the lie of the foetus is to be strongly deprecated. Rh haemolytic disease of the newborn which is a genetically determined immunological reaction to Rh incompatibility is now preventable by immunization against the D antigen (9).

3. Early diagnosis and treatment

(a) Detection of genetic carriers: It is now possible to identify the healthy carriers of a number of genetic disorders, especially the inborn errors of metabolism. The female carriers of Duchenne type of muscular dystrophy, an X-linked disorder, can now be detected by elevated levels of serum creatine kinase in 80 per cent of carriers. In some conditions, carriers can be recognized with a high degree of certainty (e.g., ataxias); in some only a proportion of carriers can be detected (e.g., haemophilia, PKU, galactosaemia); in other conditions, no method has yet been found which will distinguish carriers (e.g., alkaptonuria) (20).

(b) Prenatal diagnosis: Amniocentesis in early pregnancy (about 14-16 weeks) has now made it possible for prenatal diagnosis of conditions associated with chromosomal anomalies (e.g., Down's Syndrome); many inborn errors of metabolism (e.g., Tay-Sachs disease, galactosaemia, Maple syrup urine disease, Alpha-thalassemia and neural tube defects). The indications for prenatal diagnosis are listed in Table 9.

Amniocentesis: Examination of a sample of amniotic fluid makes possible the prenatal diagnosis of chromosomal anomalies and certain metabolic defects. The procedure can be used as early as 14th week of pregnancy when abortion of the affected fetus is still feasible. The diagnostic chromosomal anomalies are made by culture and Karyotyping of fetal cells from the amniotic fluid, and of metabolic defects by biochemical analysis of the fluid.

Amniocentesis is called for in the following circumstances if the parents are prepared to consider abortion:

1. A mother aged 35 years or more (because of high risk of Down’s syndrome with advanced maternal age).
2. Patients who have had a child with Down’s syndrome or other chromosomal anomalies.
3. Parents who are known to have chromosomal translocations.
4. Parents who have had a child with a metabolic defect — detectable by amniocentesis. The most common defects of the neural tube, anencephaly and spina bifida which can be detected by an elevation of alpha fetoprotein in the amniotic fluid.
5. When determination of the sex is warranted, given a family history of a sex-linked genetic disease, e.g., certain muscular dystrophies.

For the detection of neural tube defects there is now the possibility of an amniocentesis performed by the determination of alpha-fetoprotein levels in the maternal serum. If the test is positive it can be confirmed by amniocentesis.

(c) Screening of newborn infants: We have today a long list of screening tests for the early diagnosis of genetic abnormalities — sex chromosome abnormalities, congenital dislocation of hip, PKU, congenital hypothyroidism, sickle cell disease, cystic fibrosis, Duchenne muscular dystrophy, congenital adrenal hyperplasia, glucose 6-phosphate deficiency, etc.

Neonates should be routinely examined for congenital abnormalities, particularly dislocation of the hip, which can be simply corrected at this stage. Biochemical screening of newborn infants was first used for PKU in 1966. heel-stick blood samples are usually collected at 5–10 days after birth. Several drops of blood are collected on filter paper (the Guthrie card), which is sent to screening laboratory. Screening of newborns for congenital hypothyroidism is carried out in most developed countries. Sickle-cell disease can be detected cheaply and reliably by hemoglobin electrophoresis using Guthrie blood spots. Neonatal screening for cystic fibrosis is based on the measurement of immunoactive trypsin in Guthrie blood spots.

(d) Recognizing pre-clinical cases: We have today a pretty long list of screening tests for the early diagnosis of hereditary diseases. For example, hyperglycemia for phenylketonuria can be detected by a phenylalanine tolerance test. A simple urine examination for sugar after morning breakfast is good enough to detect diabetics. Examination of saliva and close relatives of diabetics by a glucose tolerance test will often reveal preclinical cases of acholic jaundice. A raised serum uric acid should arouse suspicion of gout. Sickle cell trait can be uncovered by subjecting the red cells to reduced oxygen tension. Thalassaemia minor can be detected by studying the blood picture.

Genetic counselling can have the greatest impact when individuals or couples at genetic risk are identified prospectively. i.e., before they have developed symptoms themselves or produced their first affected child. Prospective counselling is technically possible only when carriers can be accurately identified. To some extent, these techniques and genetic population-screening services listed in Table 4 may serve as models for the development of future genetic screening programmes.

Once diagnosed, some of the genetic conditions can be treated with complete or partial success by medical and surgical measures. For example, diets low in phenylalanine are now prescribed as treatment for PKU children. Patients suffering from haemophilia can be greatly helped by administering antihaemophilic globulin, which promotes the clotting of blood. Modern surgical techniques have brought great improvements in dealing with cases of spina bifida.

Rehabilitation
Finally, rehabilitation. With many genetic or partially genetic conditions causing physical or mental disability, much can be done for the patient and for his family in helping him to lead a better and more useful life.

Health is defined as a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity. A sound mind in a sound body has been recognised as a social ideal for many centuries. The Indian sages and seers had paid particular attention to the unconscious, wherein lay the suppressed unfulfilled desires and compulsions of several thousands which led the individual astray; by mastering their minds, they attained the highest level of emotional equilibrium. Mental health is thus the balanced development of the individual's personality and emotional attitudes which enable him to live harmoniously with his fellow-men. Mental health is not exclusively a matter of relation between persons; it is also a matter of relation of the individual towards the community he lives in, towards the society of which the community is a part, and towards the social institutions which for a large part guide his life, determine his way of living, working, leisure, and the way he earns and spends his money, the way he sees happiness, stability and security (1).

In 1950, a WHO Expert Committee on mental health reviewed the various definitions of mental health and observed "Mental health, as the Committee understands it, is influenced by both biological and social factors. It is not a static condition but subject to variations and fluctuations of degree; the Committee's conception implies the capacity in an individual to form harmonious relations with others, and to participate in, or contribute constructively to, changes in his social and physical environment. It implies also his ability to achieve a harmonious and balanced satisfaction of his own potentially conflicting instinctive drives in that it reaches an integrated synthesis rather than the denial of satisfaction to certain instinctive tendencies as a means of avoiding the thwarting of others (2)."

Problem statement

WORLD: Mental disorders are not the exclusive preserve of any special group; they are truly universal. Mental and behavioural disorders are found in people of all regions, all countries and all societies. An analysis done by WHO shows that neuropsychiatric conditions, which included a selection of these disorders, had an aggregate point prevalence of about 10 per cent for adults. About 450 million people were estimated to be suffering from neuropsychiatric conditions.

INDIA: Surveys of mental morbidity carried out in various parts of the country suggest a morbidity rate of not less than 18–20 per 1,000, and the types of illness and their prevalence are very much the same as in other parts of the world. The number of specialized hospitals for mental disorder patients in the country are 47 with total number of beds about 10,329. The number of outdoor (old and new) mental disorder cases treated in these hospitals during 2004 were about 896,425 and 22,361 cases were treated in child guidance clinics. The total number of new outdoor cases during 2004 in specialized mental hospitals were 6,737 psychotic substance users, 55,869 schizophrenia, 31,555 mood disorder, 38,482 neurotic, stress related, 3,417 behavioural syndromes, 906 disorder of adult personality, 4,256 mental retardation, 885 disorder occurring in childhood, 1,151 psychological disorder, 4,577 organic disorder, and 2,904 unspecified mental disorders (3).

The new cases treated in child guidance clinics during 2004 were 447 organic and symptomatic disorders, 317 psychoactive substance users, 2,958 schizophrenia, 1,118 mood disorders, 413 neurotic and stress related, 125 behavioural syndromes, 87 disorder of adult personality, 1,126 mental retardation, 85 psychological disorder, 190 disorders occurring in childhood, and 1,022 unspecified mental disorders (4).

Characteristics of a mentally healthy person

Mental Health is not mere absence of mental illness. A mentally healthy person has three main characteristics:

1. He feels comfortable about himself, that is, he feels reasonably secure and adequate. He neither underestimates nor overestimates his own ability. He accepts his shortcomings. He has self-respect.
2. The mentally healthy person feels right towards others. This means that he is able to be interested in others and to love them. He has friendships that are satisfying and lasting. He is able to feel a part of a group without being submerged by it. He is able to like and trust others. He takes responsibility for his neighbours and his fellow-men.
3. The mentally healthy person is able to meet the demands of life. He does something about the problems as they arise. He is able to think for himself and to take his own decisions. He sets reasonable goals for himself. He shoulders his daily responsibilities. He is not bowled over by his own emotions of fear, anger, love or guilt (5).

Warning signals of poor mental health

William C. Menninger, President of the Menninger Foundation, Topeka, Kansas, United States of America drew up the following questions to aid in taking one's own mental health pulse:

1. Are you always worrying?
2. Are you unable to concentrate because of unrecognized reasons?
3. Are you continually unhappy without justified cause?
4. Do you lose your temper easily and often?
5. Are you troubled by regular insomnia?
6. Do you have wide fluctuations in your moods from depression to elation, back to depression, which incapacitate you?
7. Do you continually dislike to be with people?
8. Are you upset if the routine of your life is disturbed?
9. Do your children consistently get on your nerves?
10. Are you “browned off” and constantly bitter?
11. Are you afraid without real cause?
12. Are you always right and the other person always wrong?
13. Do you have numerous aches and pains for which no doctor can find a physical cause?

The conditions chartered in these questions are the major warning signals for poor mental health in one degree or another. According to Dr. Menninger, help is necessary if the answer to any of these questions is definitely “yes”.

Types of mental illness

Mental and behavioural disorders are understood as clinically significant conditions characterised by alternation in thinking, mood (emotions) or behaviour associated with personal distress and/or impaired functioning. Any classification of mental disorder includes syndromes and conditions. Individuals may suffer from one or more disorders during one or more periods of their life. One incidence of abnormal behaviour or a short period of abnormal mood does not of itself signify the presence of a mental or behavioural disorder.

The International Classification of Diseases (ICD–10) classifies the mental and behavioural disorders as (3):
- Organic, including symptomatic, mental disorders – e.g., dementia in Alzheimer’s disease, delirium.
- Mental and behavioural disorders due to psychoactive substance use – e.g., harmful use of alcohol, opioid dependence syndrome.
- Schizophrenia, schizoaffective and delusional disorders – e.g., paranoid schizophrenia, delusional disorders, acute and transient psychotic disorders.
- Mood (affective) disorders – e.g., bipolar affective disorder, depressive episode.
- Neurotic, stress-related and somatoform disorders – e.g., generalised anxiety disorders, obsessive-compulsive disorders.
- Behavioural syndromes associated with physiological disturbances and physical factors – e.g., eating disorders, non-organic sleep disorders.
- Disorders of adult personality and behaviour – e.g., paranoid personality disorder, transsexualism.
- Mental retardation.
- Disorders of psychological development – e.g., specific reading disorders, childhood autism.
- Behavioural and emotional disorders with onset usually occurring in childhood and adolescence – e.g., hyperkinetic disorders, conduct disorders, tic disorders.
- Unspecified mental disorder.

Mental illness is a vast subject, broad in its limits and difficult to define precisely. There are major and minor illnesses. The major illnesses are called psychoses. Here, the person is “irrational” and out of touch with reality. There are three major illnesses: (1) SCHIZOPHRENIA (split personality) in which the patient lives in a dream world of his own. (2) MANIC–DEPRESSIVE PSYCHOSIS in which the symptoms vary from heights of excitement to depths of depression, and (3) PARANOIA which is associated with undue anxiety, extreme suspicion, and a tendency to regard the whole world in a framework of delusions. The minor illnesses are of two groups: (a) NEUROSIS or PSYCHOSES: in this the patient is unable to react normally to life situations. He is not considered “insane” by his associates, but nevertheless exhibits certain peculiar symptoms such as mood, fears, compulsions and obsessions, (b) PERSONALITY AND CHARACTER DISORDERS. This group of disorders are the legacy of unfortunate childhood experiences and perceptions.

Causes of mental illhealth

Mental illness is due to many causes. There are many known factors of agent, host and environment in the natural histories of mental disorders. Among the known factors are the following: (1) ORGANIC CONDITIONS: Mental illnesses may have their origin in organic conditions such as cerebral arterioclerosis, neoplasms, metabolic diseases, neurological diseases, endocrine diseases and chronic diseases such as tuberculosis, leprosy, epilepsy, etc. (2) HEREDITY: Heredity may be an important factor in some cases. For example, the child of two schizophrenic parents is 40 times more likely to develop schizophrenia than is the child of healthy parents. (3) SOCIAL, PATHOLOGICAL CAUSES: To produce any disease, there is a complex interplay of genetic and environmental factors. The social and environmental factors associated with mental illhealth comprise: worries, anxiety, emotional stress, tension, fatigue, unhappy marriages, broken homes, poverty, industrialization, urbanization, changing family structure, population mobility, economic insecurity, credit, rejection, neglect and the like. The social environment not only determines the individual’s attitudes but also provides the “framework” within which mental health and illness may develop.

Environmental factors other than psychosocial ones capable of producing abnormal human behaviour are: (1) Toxic substances – carbon disulphide, mercury, manganese, tin, lead compounds, etc. (2) Psychotropic drugs – barbiturates, alcohol, griseofulvin. (3) Nutritional factors – anorexia nervosa, pyridoxine. (4) Minerals – deficiency of iodine. (5) Infective agents – infectious disease (e.g., measles, rubella) during the prenatal, perinatal and postnatal periods of life may have adverse effects on the brain’s development and the integration of mental functions. (6) Traumatic factors – road and occupational accidents and (7) Radiation – nervous system is most sensitive to radiation during the period of neural development.

Crucial points in the lifecycle of human beings

There are certain key points in the development of the human being which are important from the point of view of mental health. These are: (1) Prematernal period: Pregnancy is a stressful period for some women. They need help not only for their physical but also emotional needs. (2) First 5 years of life: The roots of mental health are in early childhood. The infant and young child should experience a warm, intimate and continuous relationship with his mother and father. It is in this relationship where underlies the development of mental health. It follows that brokets homes
are likely to produce behaviour disorders in children and this has been confirmed by several studies. (3) School child: Everything that happens in the school affects the mental health of the child. The programmes and practices of the school may satisfy or frustrate the emotional needs of the child. Children who have emotional problems may need child guidance clinic or psychiatric services. From the standpoint of the child’s mental health and his effectiveness in learning, positive teacher-pupil interaction and good organisation of the class room are very important. (4) Adolescence: The transition from adolescence to manhood is often a stormy one and fraught with dangers to mental health, manifested in the form of mental illness among the young, and juvenile delinquents in particular. The basic needs of the adolescents are: (a) the need to be needed by others, (b) the need for increasing independence, (c) the need to achieve adequate adjustment to the opposite sex and (d) the need to rethink the cherished beliefs of one’s elders. The failure to recognize and understand these basic needs may prevent sound mental health. (5) Child age: The mental health problems of the aged have received considerable attention in recent times in the developed countries. The cases of mental illness in the aged are organic conditions of the brain, economic insecurity, lack of a home, poor status and insecurity. Thus throughout his life, the needs of man remain the same: (1) the need for affection, (2) the need for belonging, (3) the need for independence, (4) the need for achievement, (5) the need for recognition or approval, (6) the need for a sense of personal worth and (7) the need for self-actualisation. These needs only differ in degree and qualitative importance at various ages.

Preventive aspects

Three levels of prevention have been described (7).

(1) Primary: Primary prevention operates on a community basis. This consists of “improving the social environment”, and promotion of the social, emotional and physical well-being of all people. It includes working for better living conditions and improved health and welfare resources in the community.

(2) Secondary: This consists of early diagnosis of mental illness and of social and emotional disturbances through screening. This consists of “improving the social environment”, and provision of treatment facilities and effective community resources. In this regard, “family-based” mental health services have (3). (3) Child age: The family service agencies identify emotional problems and early symptoms of mental illness, help family members to cope with overwhelming stress, treat problems of individual and social maladjustment when required and prepare individual family members for psychiatric care. “Case work” or “counselling” is the method most commonly employed by the family service agencies. The agencies, main responsibility is to provide a counselling service and help to families with marital conflict, disturbed parent-child relations, and strain between interpersonal relationships.

Family counselling is one method of treatment intervention for helping the mentally ill. Family counsellors make an accurate psychosocial diagnosis.

(3) Tertiary: Tertiary prevention seeks to reduce the duration of mental illness and thus reduce the stresses they create for the family and the community. In short, the goal at this level is to prevent further break-down and disruption.

Mental health services

Mental health services in a community are concerned not only with early diagnosis and treatment, but also with the prevention and promotion of good mental health and prevention of mental illness. The mental health services comprise:

(1) Early diagnosis and treatment.
(2) Rehabilitation.
(3) Group and individual psychotherapy.
(4) Mental health education.
(5) Use of medicines and psychoactive drugs.
(6) After-care services.

Comprehensive mental health programme

Since 95 percent of psychiatric cases can be treated with or without hospitalisation close to their homes, the current trend is full integration of psychiatric services with other health services. The Community Mental Health Programme includes all community facilities pertinent in any way to prevention, treatment and rehabilitation. The philosophy of Community Mental Health Programme consists of the following essential elements: (1) In-patient services (2) Out-patient services (3) Partial hospitalisation (4) Emergency services (5) Diagnostic services (6) Pre-care and after-care services including foster home placement and home visiting (7) Education services (8) Training, and (9) Research and evaluation.

ALCOHOLISM AND DRUG DEPENDENCE

Definition

The word “drug” is defined as “any substance that, when taken into the living organism, may modify one or more of its functions” (WHO). “Drug abuse” is defined as self-administration of a drug for non-medical reasons, in quantities and frequencies which may impair an individual’s ability to function effectively, and which may result in social, physical, or emotional harm. “Drug dependence” is described as “a state, psychic and sometimes physical, resulting from the interaction between a living organism and a drug, characterised by behavioural and other responses that always include a compulsion to take the drug on a continuous or periodic basis in order to experience its psychic effects, and sometimes to avoid the discomfort of its absence. A person may be dependent upon more than one drug (8, 9).

The problem

The non-medical use of alcohol and other psychoactive drugs has become a matter of serious concern in many countries. While alcohol abuse is a more or less universal problem, the incidence of drug abuse varies from place to place. An estimated 12–20 million people smoke marijuana in the USA, 30–50 percent of all high school students had marijuana an accepted part of life (10). Experience in Sweden indicates that drug dependence reached a peak in the age-group 12–20 years and the problem is less among girls. The problem of drug dependence has reached epidemic proportions in many countries (11).

Agent factor

Dependence-producing drug

A dependence-producing drug is one that has the capacity to produce dependence, as described above. The specific characteristics of dependence varies with the type of
drug involved. ICD-10 recognizes the following psychoactive drugs, or drug classes, the self administration of which may produce mental and behavioural disorders, including dependence:
1. Alcohol
2. Tobacco
3. Cannabis
4. Sedatives or hypnotics
5. Cocaine
6. Other stimulants including caffeine
7. Hallucinogens
8. Tobacco
9. Volatile solvents
10. Other psychoactive substances, and drugs from different classes used in combination.

Although the dependence-producing properties and public health problems caused by tobacco were recognized long ago, its acute effects on the body were minimal. The WHO Expert Committee on drug dependence at its meeting in Sept. 1992 felt that tobacco and other forms of nicotine use warranted their inclusion in the report. Furthermore, it recommended that WHO should consider expanding the Committee's term of reference to include substances such as anabolic steroids, which are used because of their performance-enhancing effects. Anabolic steroids are being abused by people who wish to increase muscle mass for cosmetic reasons or for greater strength. In addition to the medical problems, the practice is associated with significant mood swings, aggressiveness, and paranoid delusions. Along with anabolic use is higher in these individuals. Withdrawal symptoms of steroid dependence include fatigue, depressed mood, asthenia, and insomnia (12).

The most important of use is described in ICD-10 under the category F_55, "Abuse of non-dependence-producing substances". The development of other performance enhancing drugs may present new types of drug use problems in the future.

The drugs which are a common use today are (13, 11, 14, 15, 16):

1. AMPHETAMINES AND COCAINE: Amphetamines are synthetic drugs, structurally similar to adrenaline. In medical practice, they are used to treat obesity, mild depression, narcolepsy and certain behaviour disorders in children. The ordinary therapeutic dose is 10–30 mg a day. There are various brands of amphetamines: the common names are Benzedrine, Dexedrine, Methedrine, etc. These drugs act on the central nervous system. They produce mood elevation, elation, a feeling of well-being and increased alertness and a sense of heightened awareness. Because they give a tremulant effect needed to set up the body, the mood becomes more consistent, while increasing endurance, they are called "superman" drugs. The use of these drugs results in psychic dependence. With large doses, a marked depression, a state of rapid and strong

Cocaine is derived from the leaves of the coca plant. It was formerly used in medical practice as a potent local anaesthetic. Cocaine is a central nervous stimulant. It produces a sense of excitement, heightened and distorted awareness and hallucinations. Unlike amphetamines, it produces no tolerance. There is a "no physical dependence; no withdrawal symptoms". The chewing of coca leaves is a very common practice in Bolivia and Peru in South America.

2. BARBITURATES: If amphetamines stimulate, barbiturates sedate. They are a major ingredient in sleeping pills. The drug-users generally prefer short-acting barbiturates such as pentobarbital and secobarbital to long acting ones. The addiction to barbiturates is one of the worst forms which leads to craving, or both physical and psychic dependence.

3. CANNABIS: Perhaps, the most widely used drug today is Cannabis. It is a plant from the hemp plants - Cannabis sativa, C.indica and C. americana. The resinoid exudate from the flowering tops of the female plant contains most of the active ingredients – called hashish or charas. The dried leaves and flowering shoots are called bhang; the resinous mass from the small leaves and brackets of inflorescence is called ganja. In USA, the term marijuana is used to refer to any part of the plant which induces somatic and psychic changes in man. Most commonly the plant is cut, dried, chopped and incorporated into cigarettes. It is also taken with drinks or incorporated in foods like sweets and cakes. A marijuana cigarette or pipe produces intoxication within minutes and lasts from 1 to 4 hours. The oral consumption results in a delayed onset of action and a prolonged effect lasting many hours.

The most common reaction is the development of a dreamy state of altered consciousness. Relaxation, euphoria, and an increased tendency to laugh, greater awareness of colours and sounds, interference with perception of both time and space, and paranoia are among the psychological effects reported by marijuana users. Human death appears to be a rare phenomenon. There is a psychic dependence.

4. HEROIN: Heroin, morphine, codein, methadon, pethidine are narcotic analgesics. Addition to heroin is perhaps the worst type of addiction because it produces craving. With narcotics generally psychic dependence is strong and tends to develop early. Tolerance to narcotics also occurs rapidly, making it necessary to take increasing doses of the drug to achieve the same effect.

5. LSD: Lysergic acid diethylamide (LSD) was synthesized in 1938 by Hoffmann in the Sandoz Laboratories in Switzerland. Its psychotropic properties were noticed much later in 1943, when he accidentally snorted a few micrograms of it. LSD is a potent psychotogenic agent. Although amounts as low as 25–25 μg may produce subjective disturbances, oral doses in the range of 100–250 μg are usually required to effect intense depersonalization. The lethal dose in man is not known.

LSD distorts the normal structuring of perception. The individual perceives the world in a different manner. There is intensification of colour perception and auditory acuity; body image distortions, visual illusions, fantasies pseudo-hallucinations are common. Colours are heard and music becomes palpable. Subjective time is deranged so that seconds seem to be minutes and minutes pass as slowly as hours.

Physical dependence does not develop with LSD; hence there is no addiction liability. No characteristic abstinence syndrome is manifested upon abrupt discontinuation of chronic use of the drug.

6. ALCOHOL: By pharmacological definition, alcohol is a drug and may be classified as a sedative, tranquilizer, hypnotic or anaesthetic, depending upon the quantity consumed. Of all the drugs, alcohol is the only drug whose self-induced intoxication is socially acceptable.

Alcohol is rapidly absorbed from the stomach and small intestine. Within 2–3 minutes of consumption, it can be
detected in the blood – the maximum concentration is usually reached about one hour after consumption. The presence of lead in the stomach inhibits the absorption of alcohol because of dilution.

Over the past 30–40 years, increasing percentages of young people have started to drink alcoholic beverages, their alcohol consumption has increased in quantity and frequency, and the age at which drinking starts has declined (13). This situation is a disturbing because the young people concerned may run a greater risk of alcoholic problems in later life also, in the short term, because of increased rates of drunkenness and involvement in road accidents.

Worldwide, an estimated 2.3 million people die from alcohol-related causes. This is 3.7 per cent of all deaths; 6.1 per cent among men and 1.1 per cent among women. Also, 64.9 million DALYs are lost due to alcohol related causes. WHO has estimated that there are about 2 billion people worldwide who consume alcoholic beverages and 76.3 million with disorders arising out of harmful use of alcohol. Unintentional injuries and suicides account for large number of deaths due to alcohol (19).

In India, survey showed that around 20–30 per cent of adult males and around 5 per cent of adult females use alcohol. While alcohol is used traditionally by men, its use by women is now on the increase. The proportion of dependent users is large. Issues of concern include pay-day drinking, violence including domestic violence, alcohol's contribution to poverty, illicit and home-brewed alcohol, and reduction in average age of initiation (19). In a study in Bangalore, nearly 28 per cent of traffic injuries were found directly attributable to alcohol. Alcohol use is considered a risk factor for high risk sexual behaviour leading to sexually transmitted diseases including HIV/AIDS.

Alcohol has a marked effect on the central nervous system. It is not a “stimulant” as long believed, but a primary and continuous depressant. Alcohol produces psychic dependence of varying degrees from mild to strong. Physical dependence develops slowly.

According to current concepts, alcoholism is considered a disease and alcohol a “disease agent” which causes acute and chronic intoxication, cirrhosis of the liver, toxic psychosis, gastritis, pancreatitis, cardiomyopathy and periperal neuropathy. Also, evidence is mounting that it is related to cancer of the mouth, pharynx, larynx and oesophagus. Further, alcohol is an important aetologic factor in suicide, automobile and other accidents, and injuries and deaths due to violence. The health problems for which alcohol is responsible are only part of the total social damage which includes family disorganization, crime and loss of productivity.

(7) TOBACCO: Tobacco is in legal use everywhere in the world, yet it causes far more deaths than all other psychoactive substances combined. About 3 million premature deaths a year (6 per cent of the world total) are already attributed to tobacco smoking. Tobacco is responsible for about 30 per cent of all cancer deaths in developed countries. More people die from tobacco-related diseases other than cancer such as stroke, myocardial infarction, aortic aneurysm and peptic ulcer. Young people who take up smoking have been shown to experience an early onset of cough, phlegm production, and shortness of breath on exertion. There is evidence that the earlier a person begins to smoke the greater is the risk of life-threatening diseases such as chronic bronchitis, emphysema, cardiovascular disease, and lung cancer. Experimentation with smoking as a symbol of “adult” behaviour is common in adolescence. It is suggested that three factors are associated with young people smoking: peer pressure following the example of siblings and parents, and employment such as the home. In a child's earlier sibling and both parents smoke, the child is four times as likely to smoke as one with no smoking model in the family (13).

Women who smoke run even less risk than men. For example, the adverse effects of oral contraceptive use are markedly increased in women smokers. Osteoporosis is accelerated with tobacco use. Some evidence indicates that fertility is impaired with smoking. Tobacco use is also associated with a higher rate of spontaneous miscarriages, intrauterine growth retardation and low birth-weight babies are known out-come of smoking during pregnancy (17). The babies of mothers who smoke may weigh, on an average, 200 grams less at birth than those of non-smokers (16). The harm from maternal smoking can extend beyond pregnancy, affecting the child's growth and development. This is often compounded by the child's exposure to second-hand smoke from parents and other adults.

Passive smoking

Second-hand tobacco smoke is the combination of smoke emitted from the burning end of a cigarette or other tobacco products and smoke exhaled by the smoker.

Smoking harms non-smokers too. The first conclusive evidence of the danger of passive smoking came from a study carried out in Hiroshima. In 1961, lung cancer in non-smoking Japanese wives married to men who smoked. Surprisingly at the time, those women showed a significantly increased risk of dying from lung cancer, despite never having smoked a cigarette. Hirayama believed that passive smoking (i.e. breathing in the smoke from their husbands) caused these women's excess cancer risk. About 40 further studies have confirmed this link.

Today, research indicates that passive smoking can also give rise to other potentially fatal diseases such as heart disease and stroke, and new scientific evidence of the adverse effects of second-hand smoke continues to accumulate (17).

Per capita consumption of tobacco is decreasing slowly in developed countries. By contrast, per capta tobacco consumption is rising in many developing countries among both men and women. Because of the long delay between the cause and full effect, people tend to misjudge the hazards of tobacco. When a generation of young people begin to smoke, they do not witness the high morbidity and mortality associated with their behaviour until they reach middle age. The best documented example of this delay is that of men in the USA, among whom the main increase in smoking took place before 1945. In 1945 smoking was common but lung cancer was rare as in developing countries today. Over the next forty years (1945–1985) the smoking habit did not change greatly, but lung cancer in this population rose sharply – about twenty-fold, whereas non-smokers lung cancer remained approximately constant at a low level during 1945–1985. About half of those killed by tobacco were still in middle age (35–69) and thereby lost almost twenty-five years of non-smoker life expectancy (16).
Mental Health

Since the mechanization of cigarette manufacturing at the turn of the 20th century, global consumption of cigarettes has been rising steadily. Today, more people are smoking, and consuming more cigarettes per capita, than ever before. At present, about 1070 million males and 230 million females in the world smoke, generating an epidemic of global magnitude. In developed countries, the prevalence of smoking among adult males is decreasing, but the increasing number of adult male smokers in developing countries offsets this. Smoking is still rising among females in developing countries, with the exception of a few countries such as Australia, Canada, United Kingdom and the United States. With the expansion of the tobacco industry’s marketing campaigns into the developing world, more and more people are taking up smoking in countries least able to deal with the grave public health consequences of tobacco use. China produces about a third of all the cigarettes in the world. It is also a major tobacco consumer, since nearly 60% of adult Chinese males smoke, representing one-third of all smokers globally. Currently, it is estimated that one out of every three cigarettes in the world is smoked in China. According to Global Adult Tobacco Survey, India (2009-2010), the prevalence of overall tobacco use among males is 48 per cent and that among females is 20 per cent. Nearly 38 per cent adults in rural areas and 25 per cent in urban areas use tobacco in some form. Prevalence of smoking among males is 24 per cent whereas prevalence among females is 3 per cent. The extent of use of smokeless tobacco products among males is 33 per cent and in females 18 per cent (18).

A variety of smokeless tobacco products are also consumed in South East Asia Region. Pan masala, gutkha (industrially manufactured chewing tobacco product), khaini (chewing of dry tobacco leaves and lime), and chewing tobacco with areca nuts are common in India, Bangladesh, Bhutan, Nepal and Myanmar. Smokeless tobacco use is more prevalent among men than among women in these countries excepting in Bangladesh, where smokeless tobacco use is more prevalent among women (19).

The adverse health effects of smoking are as shown in Table 1.

The withdrawal symptoms include irritability, anxiety, craving, sleep problems, headache, tremors, and lethargy. Withdrawal symptoms may continue for 4-6 weeks, and craving may continue for many months.

(8) VOLATILE SOLVENTS : In a number of countries, the sniffing of substances such as glue, petrol, diethyl ether, chloroform, nitrous oxide, paint thinner, cleaning fluids, typewriter correction fluid etc., is causing increasing concern, as it can result in death, even on the first occasion. These substances are central nervous system depressants.

and produce effects comparable to those produced by alcohol. There may be initial euphoria and exhilaration, followed by confusion, disinhibition and ataxia. Some of the substances like petrol and toluene may also produce marked euphoria, grandiosity, recklessness, delusions and hallucinations and a substantial loss of self-control. With increasing dosage, there may be convulsions, coma and death. In chronic abusers damage to the brain, peripheral nervous system, kidney, liver, heart or bone marrow may occur (13). Lead encephalopathy can be associated with stuffing lead gasoline.

8) CAFFEINE: Caffeine is one of the most commonly used drug worldwide. About 10 billion pounds of coffee are consumed yearly throughout the world. Tea, cocoa, and cola drinks also contribute to an intake of caffeine that is often very high in a large number of people. The approximate content of caffeine in a cup (180 ml) of beverage is as follows : Brewed coffee 80-140 mg; instant coffee 60-100 mg; decaffeinated coffee 1-6 mg; black tea 30-80 mg; tea bags 25-75 mg; instant tea 30-60 mg; cocoa 10-50 mg; and 12 oz cola drinks 30-60 mg. Symptoms of caffineism (usually associated with ingestion of over 500 mg/day) include anxiety, agitation, restlessness, insomnia and somatic symptoms referable to the heart and gastrointestinal tract. Withdrawal from caffeine can produce headache, irritability, lethargy, and occasional nausea (12).

Host factors

Many attempts have been made to define the host factors. Studies employing questionnaires or structured interviews report motivs for drug dependence with descriptive words such as pleasure, desire to experiment, sense of adventure, wish for self-knowledge, and desire to escape. Increasingly, people are unwilling to accept even minor discomforts and are looking to drugs for solutions. Many of them have shown symptoms of social and psychological maladjustment resulting from personal handicap of all sorts. The average age of drug users has decreased considerably in recent years. Multiple drug-use has also become more common. Concern over drug-use by teenagers increased in the late 1960s, particularly in the developed countries. In countries with long experience of heavy drug use, there is a tendency to prefer a single drug, perhaps because a continuous supply is less problematic. Multiple drug use may be more common where drug abuse is a relatively recent occurrence.

Symptoms of drug addiction

1. Loss of interest in sports and daily routine;
2. Loss of appetite and body weight;
3. Unsteadiness, loose grasp, movements, tremors;
4. Reddening and puffiness of eyes, unclear vision;
5. Slurring of speech;
6. Fresh, numerous injection marks on body and blood stains on clothes;
7. Nausea, vomiting and body pain;
8. Drowsiness or sleeplessness, lethargy and passivity;
9. Acute anxiety, depression, profuse sweating;
10. Changing mood, temper, tantrums;
11. Depersonalisation and emotional detachment;
12. Impaired memory and concentration; and
13. Presence of needles, syringes and strange packets at home.

Environmental factors

Among the environmental factors attributed to drug dependence are rapid technological developments with associated need for extended periods of education, along with the in-applicability of old solutions to novel problems. Television, world travel, affluence, freedom to speculate and experiment have encouraged youngsters to question and often reject the values and goals of their parents. Established social values are perceived as irrelevant, all to be stripped away, partly through the use of drugs in order to reveal the real person, the real humanity, and the real goals of mankind. Sensitivities confirm that those who take drugs usually form part of a small antisocial and often criminal subculture. The problem exists in virtually all societies and socio-economic groups. Some of the social and environmental factors associated with a high risk for drug abuse are listed in Table 2.

TABLE 2

Factors associated with a high risk for drug abuse

- unemployment
- living away from home
- migration to cities
- relaxed parental control
- alienation from family
- early exposure to drugs
- leaving school early
- broken homes; one parent families
- large urban environments
- areas where drugs are sold, traded, or produced
- certain occupations
- tourism, drug production or sale
- areas with high rates of crime or vice
- areas where there are drug-selling gangs
- areas where delinquency is common

Prevention

Approaches to prevention of drug dependence should have realistic aims. Over-ambitious hopes of eradicating a drug problem in a short time are likely to lead to policies that are unrealistic and self-defeating. Changes in culture attitudes and alteration in relevant aspects of the environment can be brought about only slowly.

Legal approach: The legal control on the distribution of drugs, when effectively applied has been and remains an important approach in the prevention of drug abuse. Controls may be designed to impose partial restriction or to make a drug completely unavailable. Legislation may be directed at controlling the manufacture, distribution, prescription, price, time of sale, or consumption of a substance. Legislation restricting or prohibiting advertisements that directly or indirectly promote use of tobacco and alcohol has been increasingly common in recent years. The antismoking measures suggested are: (a) prohibition of the sale of tobacco products to minors; (b) restriction on the sale of cigarettes from automatic vending machines; (c) prohibition of smoking in schools and other places frequented by young people; (d) prohibition of smoking in public; (e) prohibition of cigarette advertising at times, and in places and ways, calculated to ensure its maximum impact on adolescents; (f) establishment of mandatory public health education on health consequences of smoking; (g) insisting on the placing of mandatory health warning on cigarette packets. The minimum age at which minors may legally have
access to alcoholic beverages, has been raised in some
countries. There is also legislation controlling the
distribution of alcohol in some countries. Mandatory jail
sentences for drunken driving have not been very effective.

Educational approach: Educational approaches to the
prevention of drug use and drug-related problems have been
used in many countries. Common approaches have included
educational programmes for school children and public
information campaigns on electronic media. General
principles of communication can be applied to increase the
effectiveness of educational approach. The message should
to the end unambiguous to the intended audience and
come from credible source of information. The message
should also provide specific advice, rather than general,
and as far as possible the information should be new to the
audience and should be capable of provoking discussion
or action. Educational approach should not be planned and
varied out as isolated activity. To be effective, such
approaches should be regarded as a part of integrated plan
of action involving other strategies.

Community approach: The non-medical use of the drugs
individually as well as in its mass appearance involves a
complex interaction of drug, man, and his environment,
including social, economic, cultural, political and other
elements of viewing character and strength. The rapid
changes taking place at the present time in relations between
individuals, groups and nations are also reflected in a
rapidly changing pattern of drug abuse in many parts of the
world. There should be a strong emphasis on action at the
community level to prevent drug abuse. Initiating preventive
interventions in the community brings preventive action to
the level of people's every day lives and actions, and
contributes to emphasis on strengthening primary health
care. Action at the community level is also important since
communities often bear the main burden of dealing with the
harmful use of drugs and related problems.

A popular approach to the prevention of drug abuse is
provision of alternative activities which may help to prevent
abuse—e.g., teen centres providing activities attractive to
the young which might otherwise drift into drug taking sub-culture. Such activities include the establishment of
groups or organizations interested in athletics, sports,
music, art and other interests and activities. Various kinds,
and improvement of the environment through the
prevention of pollution. Non-governmental organizations
play a crucial role in the development of such activities and
are likely to become important.

Treatment

Treatment cannot take place unless the individual attends
for treatment. He must come to terms with the possibility of
a life without drug taking. Unfortunately, drug takers, as a
rule, have little or no motivation to undergo treatment.
Alcoholics tend to deny that their consumption is abnormal;
others openly defend their habits. Long term treatment is
not only a medical problem, but needs the cooperation of
psychologists and sociologists. There is a high relapse rate
with all treatment methods (16).

Though drug addiction may be considered as a social
problem, the first step in its management is medical care, which
includes:

- identification of drug addicts and their motivation for
detoxification
- detoxification (requires hospitalization)
- post-detoxification counselling and follow-up
  (based on clinic and home visits), and
- rehabilitation.

Simultaneously with medical treatment, changes in
environment (home, school, college, social circles) are
important. The patient must effect a complete break with his
group. otherwise the chance of relapse are 100 per cent.
Psychotherapy has a valuable place in the management of
the addict.

Rehabilitation

The rehabilitation of former drug user, regardless of age,
is in most cases a long and difficult process. Relapses are
very frequent. Success of the treatment necessitates the
adoption of mature and realistic attitude by the local
community and the avoidance of panic, moral
condemnation and discrimination. Facilities for vocational
training and sometimes the provision of sheltered work
opportunities are useful in rehabilitation and help to prevent
relapse. Generally speaking, facilities for the registration,
diagnosis treatment, after-care, etc., of drug-dependent
individuals and groups should be regarded as indispensable
integrated parts of the health and social services structure of
any community in which drug-dependence exists.

It is suggested that when there is evidence of significant
"alienation" among a group, especially of youngsters persons,
it should be regarded as indication of possible presence of
actual or potential drug-takers, and should lead to an
analysis of the situation and to such preventive or remedial
action as may be indicated.

References

Health information is an integral part of the national health system. It is a basic tool of management and a key input for the progress of any society. A health information system is defined as:

"a mechanism for the collection, processing, analysis and transmission of information required for organizing and operating health services, and also for research and training" (1, 2).

The primary objective of a health information system is to provide reliable, relevant, up-to-date, adequate, timely and reasonably complete information for health managers at all levels (i.e., central, intermediate and local), and at the sharing of technical and scientific (including bibliographical) information by all health personnel participating in the health services of a country; and also to provide at periodic intervals, data that will show the general performance of the health services and to assist planners in studying their current functioning and trends in demand and work load.

Unfortunately, it is still very difficult to get the information where it matters most — i.e., at the community level. It is conceded that no country at the present time has such a thoughtfully constructed system of health information in operation, but the concept is receiving much attention. The whole science of health statistics has undergone considerable changes in the past two decades (3). In 1973, the World Health Assembly stressed the need for complete reconstruction of the health information system.

Distinction between data and information

There is more than a subtle semantic difference between "data," "information," and "intelligence." Data consists of discrete observations of attributes or events that carry little meaning when considered alone, as data collected from operating health care systems or institutions. A good effort is inadequate for planning. Data need to be transformed into information by reducing, summarizing, and adjusting them for variations, such as the age and sex composition of the populations so that comparisons over time are possible. It is the transformation of information through integration and processing with experience and perception based on social and political values that produces intelligence (4).

Data that are not transformed into information, and information that is not transformed into intelligence to guide decision-makers, policy-makers, planners, administrators and health care personnel themselves, are of little value.

Requirements to be satisfied by health information systems

A WHO Expert Committee (5) identified the following requirements to be satisfied by the health information systems:

1. The system should be population-based.
2. The system should avoid the unnecessary agglomeration of data.
3. The system should be problem-oriented.
4. The system should employ functional and operational terms (e.g., episodes of illness, treatment regimens, laboratory tests).
5. The system should express information briefly and imaginatively (e.g., tables, charts, percentages), and
6. The system should make provision for the feedback of data.

Components of a health information system

The health information system is composed of several related subsystems. A comprehensive health information system requires information and indicators on the following subjects (6):

1. Demography and vital events
2. Environmental health statistics
3. Health status: morality, morbidity, disability, and quality of life
4. Health resources: facilities, beds, manpower
5. Utilization and non-utilization of health services: attendance, admissions, waiting lists
6. Indices of outcome of medical care, and
7. Financial statistics (costs, expenditure) related to the particular objective.

Uses of health information

The important uses to which health information may be applied are:

1. To measure the health status of the people and to quantify their health problems and medical and health care needs.
2. For local, national, and international comparisons of health status. For such comparisons the data need to be subjected to rigorous standardization and quality control.
3. For planning, administration, and effective management of health services and programmes.
(4) for assessing whether health services are accomplishing their objectives in terms of their effectiveness and efficiency.

(5) for assessing the attitudes and degree of satisfaction of the beneficiaries with the health services received.

(6) for research into particular problems of health and disease.

Sources of health information

The lifeblood of a health information system is the routine health statistics. Information requirements will vary according to the administrative level at which planning is envisaged. For example, the information requirements of a public health administrator will be different from the information requirements of a hospital administrator. These different contexts require different sources of information. These are discussed in this section.

1. Census

The census is an important source of health information. It is taken in most countries of the world at regular intervals, usually of 10 years. A census is defined by the United Nations as "the total process of collecting, compiling and publishing demographic, economic and social data pertaining at a specified time or times, to all persons in a country or specified territory" (7). Census is a massive undertaking to contact every member of the population in a given time and collect a variety of information. It needs considerable organization, a vast preparation and several years to analyse the results. This is the main drawback of census as a data source — i.e., the full results are usually not available quickly.

The first regular census in India was taken in 1881, and others took place at 10-year intervals. The last census was held in March 2011. The census is usually conducted at the end of the first quarter of the first year in each decade, the reason being, most people are usually resident in their own homes during that period. The legal basis of the census is provided by the Census Act of 1948. The supreme officer who directs, guides and operates the census is the Census Commissioner for India.

Although the primary function of census is to provide demographic information such as total count of population and its breakdown into groups and subgroups such as age and sex distribution, it represents only a small part of the total information collected. The census contains a mine of information on subjects not only demographic, but also social and economic characteristics of the people, the conditions under which they live, how they work, their income and other basic information. These data provide a frame of reference and base line for planning, action and research not only in the field of medicine, human ecology and social sciences but in the entire governmental system. Population census provides basic data (such as population by age and sex) needed to compute vital statistical rates, and other health, demographic and socio-economic indicators. Without census data, it is not possible to obtain quantified health, demographic and socio-economic indicators.

2. Registration of vital events

Vital registration is an intermittent counting of population, registration of vital events (e.g., births, deaths) keeps a continuous check on demographic changes. Registration of vital events is complete and accurate, it can serve as a reliable source of health information. Much importance is therefore given to the registration of vital events in all countries. It is the precursor of health statistics. Over the years, it has dominated the health information system.

The United Nations defines a vital events registration system as including "legal registration, statistical recording and reporting of the occurrence of, and the collection, compilation, presentation, analysis and distribution of statistics pertaining to vital events, i.e., live births, deaths, foetal deaths, marriages, divorces, adoptions, legitimations, recognitions, annulments and legal separations" (7). Registration of vital events has been the foundation of vital statistics.

India has a long tradition of registration of births and deaths. In 1877, the Govt. of India introduced the "Vital Registration Act" and established the Deaths and Marriages Registration Act, but the Act provided only for voluntary registration. Subsequently, individual States like Tamil Nadu, Karnataka and Assam passed their own Acts. However, the Registration system in India tended to be very unreliable, the data being grossly deficient in regard to accuracy, timeliness, completeness and coverage. This is because of illiteracy, ignorance, lack of concern and motivation. There are also other reasons such as lack of uniformity in the collection, compilation and transmission of data which is different for rural and urban areas, and multiple registration agencies (e.g., health agency, panchayat agency, police agency and revenue agency).

The Central Births and Deaths Registration Act, 1969

In an effort to improve the vital registration system, the Govt. of India promulgated the Central Births and Deaths Registration Act in 1969. The Act came into force on 1 April 1970. The Act provides for compulsory registration of births and deaths throughout the country, and compilation of vital statistics in the States so as to ensure uniformity and comparability of data. The implementation of the Act required adoption of rules for which also, model guidelines have been provided. The Act also fixes the responsibility for reporting births and deaths. While the public (e.g., parents, relatives) are to report events occurring in their households, the heads of hospitals, nursing homes, hotels, jails or deathshouses are to report events occurring in such institutions to the concerning Registrar. The time limit for reporting events is 48 hours for births and deaths to 2 days uniformly all over India. In case of default a late fee can be imposed. The Act makes the beginning of a new era in the history of vital statistics registration in India.

Lay reporting

Because of slow progress in the development of a comprehensive vital registration system, some countries have attempted to employ first-line health workers (e.g., village health guides) to record births and deaths in the community. Indeed, one of the important functions of a primary health worker is to collect and record data on vital events and other health information in his or her community.

In order to obtain this information, a new approach has been developed in several countries. This approach is known as "lay reporting of health information" (8). Lay reporting is defined as the collection of information, its use, and its transmission to other levels of the health system by non-professional health workers (9).

In large majority of countries properly functioning vital events registrars do not exist and it is necessary to resort to demographic surveys, etc., as an alternative source. The demographic survey, however, can never lead to the desired goal of complete recording of all vital events in a country.
Thus, where a vital events registration system is not functioning, the demographic survey should be regarded as a temporary substitute rather than a replacement (7).

3. Sample Registration System (SRS)

Since civil registration is deficient in India, a Sample Registration System (SRS) was initiated in the mid-1960s to provide reliable estimates of birth and death rates at the National and State levels. The SRS is a dual-record system, consisting of continuous enumeration of births and deaths by an enumerative and independent survey every 6 months by an investigator-supervisor. The half-yearly survey, in addition to serving as an independent check on the event record, enables the enumerator to produce the denominator required for computing rates.

The SRS now covers the entire country, and is a major source of health information. Since the interaction of this system, more reliable information on birth and death rates, age-specific fertility and mortality rates, infant, under-five and adult mortality, etc. have become available.

4. Notification of diseases

Historically notification of infectious diseases was the first health, information sub-system to be established. The primary purpose of notification is to effect prevention and/or control of the disease. Notification is also a valuable source of morbidity data, i.e., the incidence and distribution of certain specified diseases which are notifiable.

Lists of notifiable diseases vary from country to country, and also within the same country between the States and between urban and rural areas. Usual diseases which are considered to be serious menaces to public health are included in the list of notifiable diseases. Notification systems are usually operative through certain legal Acts (e.g., Madras Public Health Act, 1930). Some State Government in India do not have any specific Act, except invoking the Epidemic Diseases Act of 1897, and extending the same from year to year. The notification system is linked up with the vital statistics machinery and the reporter is often the village chowkidar or headman. With the introduction of village Health Guides and multipurpose workers, the reporting responsibility now shifts to the entire village chowkidar to the health workers. Since the legal provision is an essential pre-requisite for any notification system, the enactment of a uniform Act similar to the Registration of Births and Deaths Act, 1969 is deemed necessary for any improvement in the notification system in India.

At the international level, the following diseases are notifiable to WHO in Geneva under the International Health Regulations (IHR), viz. cholera, plague and yellow fever. A few others — louse-borne typhus, relapsing fever, polio, influenza, malaria, rickets and salmonellosis are subject to international surveillance. This information is published by WHO on a world-wide basis. The Expert Committee on Health Statistics in its third Report (10) recommended that yearly data of notification should be detailed by age and sex.

Although notification is an important source of health information, it is common knowledge that it suffers from serious limitations: (a) notification covers only a small part of the total sickness in the community (b) the system suffers from a good deal of under-reporting (c) many cases especially of subclinical cases escape notification due to non-recognition, e.g., rubella, non-paralytic polio, etc. The accuracy of diagnosis and thereby of notification depends upon the availability of facilities for bacteriological, virological and/or pathological examination. The lack of such facilities in the rural areas of India also works against the correct reporting of the causes of sickness and death.

Inspite of the above limitations, notification provides valuable information about fluctuations in disease frequency. It is also helpful in framing new policies for the prevention or outbreak of disease. The concept of notification has been extended to many non-communicable diseases and conditions like mental illness, stroke, and handicapped persons.

5. Hospital records

In a country like India, where registration of vital events is defective and notification of infectious diseases extremely inadequate, hospital data constitute a basic and primary source of information about diseases prevalent in the community. The eighth report of the WHO Expert Committee on Statistics (11) recommended that hospital statistics be regarded in all countries as an integral and basic part of the national statistical programme.

The main drawbacks of hospital data are: (a) they constitute only the "tip of the iceberg" — i.e., they provide information on only those patients who seek medical care, but not on a representative sample of the population. Mild cases may not attend hospitals; subclinical cases are always missed (b) the admission policy may vary from hospital to hospital; therefore hospital statistics tend to be highly selective (c) population served by a hospital (population at risk) cannot be defined. There are no precise boundaries to the catchment area of a hospital. In effect, hospital statistics provide only the "numerator" (i.e., the cases), not the denominator. Extrapolation of hospital data to an entire community is highly conjectural in estimating frequency rates of disease. It is also worth considering a poor guide to the estimation of disease frequency in a community.

In spite of the above limitations, a lot of useful information about patient care activities and utilization can be derived from hospital records. For example, hospital discharge sheets contain much useful information on diagnosis, medical and surgical procedures, complications, length of stay, laboratory data, etc. A study of hospital data provides information on the following aspects: (a) geographic sources of patients (b) age and sex distribution of different diseases and duration of hospital stay (c) distribution of diagnosis (d) association between different diseases (e) the period between disease and hospital admission (f) the distribution of patients according to different social and biological characteristics, and (g) the cost of hospital care. Such information may be of great value in the planning of health care services (3, 12).

Indices such as bed-occupancy rates, duration of stay, cost-effectiveness of treatment policies are useful in monitoring the use of hospital facilities. For the development of hospital statistics, the importance of establishing a medical record department in each hospital cannot be overemphasized. It is now felt that computerization of medical records will enable medical care to be more effectively rendered, better planned, and better evaluated.

6. Disease registers

The term "registration" implies something more than "notification". A register requires that a permanent record be kept for each case. This record is then used in various statistical tabulations prepared both on frequency and on survival. In addition, the patients on a register should frequently be the subjects of special studies (13).
Morbidity registers exist only for certain diseases and conditions such as stroke, myocardial infarction, cancer, blindness, congenital defects and congenital rubella. Tuberculosis and leprosy are also registered in many countries where they are common.

Morbidity registers are a valuable source of information as to the duration of illness, case fatality and survival. These registers allow follow-up of patients and provide a continuous account of the frequency of disease in the community. Even in the absence of a defined population base, useful information may be obtained from registers on the natural course of disease, especially chronic diseases in different parts of the world (12). If the reporting system is effective and the coverage is on a national or representative basis, the register can provide useful data on morbidity from the particular diseases, treatment given and disease-specific mortality.

7. Record linkage

The term record linkage is used to describe the process of bringing together records relating to one individual (or to one family), the records originating in different times or places (14). The term medical record linkage implies the assembly and maintenance for each individual in a population, of a file of the more important records relating to his health (14). The events commonly recorded are birth, marriage, death, hospital admission and discharge. Other useful data might also be included such as sickness absence from work, prophylactic procedures, use of social services, etc. Record linkage is a particularly suitable method of studying associations between diseases; these associations may have aetiological significance (13).

The main problem with record linkage is the volume of data that can accumulate. Therefore, in practice record linkage has been applied only on a limited scale e.g., twin studies, measurement of morbidity, chronic disease epidemiology and family and genetic studies. At the moment, record linkage is beyond the reach of many developing countries.

8. Epidemiological surveillance

In many countries, where particular diseases are endemic, special control eradication programmes have been instituted, as for example national disease control programmes against malaria, tuberculosis, leprosy, filariasis, etc. As part of these programmes, surveillance systems are often set up (e.g., malaria) to report on the occurrence of new cases and on efforts to control the diseases (e.g., immunizations performed). These programmes have yielded considerable morbidity and mortality data for the specific diseases.

9. Other health service records

A lot of information is also found in the records of hospital out-patient departments, primary health centres and polyclinics, polyclinics' primary health centres, another and child health centres, school health records, diabetic and hypertensive clinics, etc. For example, records in MCH centres provide information about birth weight, weight, height, arm-circumference, immunization, disease specific: mortality and morbidity. However, the drawback with this kind of data is that it relates only to a certain segment of the general population. Further the data generated by these records are mostly kept for administrative purposes rather than for monitoring.

10. Environmental health data

Another area in which information is generally lacking is that relating to the environment. Health statistics are now sought to provide data on various aspects of air, water and noise pollution; harmful food additives; industrial toxicants, inadequate waste disposal and other aspects of the combination of pollution exposure with increased production and consumption of material goods. Environmental data can be helpful in the identification and quantification of factors causative of disease. Collection of environmental data remains a major problem for the future (3).

11. Health manpower statistics

Information on health manpower is by no means least in importance. Best information relates to the number of physicians (by age, sex, specialty and place of work), dentists (classified in the same way), pharmacists, veterinarians, hospital nurses, medical technicians, etc. Their records are maintained by the State medical/dental/nursing councils and the Directorates of Medical Education. The census also provides information about occupation. The Institute of Applied Manpower Research attempts estimates of manpower, taking into account different sources of data, mortality and out-of-state qualified persons from the different institutions. The Planning Commission also gives estimates of active doctors for different States. Regarding medical education, statistics of numbers admitted, numbers qualified, are given every year in "Health Information of India", published by the Government of India, in the Ministry of Health & Family Welfare.

12. Population surveys

A health information system should be population-based. The routine statistics collected from the above sources do not provide all the information about health and disease in the community. This calls for population surveys to supplement the routinely collected statistics. The statistics available for cholera, malaria, plague, respiratory diseases, fevers and diarrhoea are of use for public health administration.

The term "health surveys" is used for surveys relating to any aspect of health — morbidity, mortality, nutritional status, etc. When the main variable to be studied is disease suffered by the people, the survey is referred to as "morbidity survey". Broadly, the following types of surveys would be covered under health survey (15):

a. Surveys for evaluating the health status of a population, that is community diagnosis of problems of health and disease. It is information about the distribution of these problems over time and space that provides the fundamental basis for planning and developing needed services; and
b. surveys for investigation of factors affecting health and disease, e.g., environment, occupation, income, circumstances associated with the onset of illness, etc. These surveys are helpful for studying the natural history of disease, and obtaining more information about disease aetiology and risk factors; and
c. Surveys relating to administration of health services, e.g., use of health services, expenditure on health, evaluation of population health needs and unmet needs, evaluation of medical care, etc.
Population surveys can be conducted in almost any setting; sampling techniques have been developed so that estimates at any level of precision desired within the constraints of available resources can be achieved (17). Health surveys may be cross-sectional or longitudinal; descriptive or analytic or both (18). Health surveys on a permanent basis are in operation in only a few countries, viz. in Japan since 1953, USA since 1957 and UK since 1971. The first methodological general health survey was carried out in Singur Health Centre by Lal and Seal in 1944-46.

Survey methods

From the point of view of the method employed for data collection, health surveys can be broadly classified into 4 types:

a. Health interview (face-to-face) survey
b. Health examination survey
c. Health records survey
d. Mailed questionnaire survey

Each method has its advantages and disadvantages. When information about morbidity is needed, Health examination surveys generally provide more valid information than health interview surveys. The survey is carried out by teams consisting of doctors, technicians and interviewers. The main disadvantage of a health examination survey is that it is expensive and cannot be carried out on an extensive scale. The method also requires considerable effort in providing treatment to people found suffering from certain diseases. The health interview (face-to-face) survey is an invaluable method of measuring subjective phenomena such as perceived morbidity, disability and impairments, economic loss due to illness, expenditure incurred on medical care; opinions, beliefs and attitudes, and some behavioural characteristics. It has also the advantage of giving population-based data. The National Sample Survey Organization in India has been active in conducting interview surveys; these surveys have provided some country-wide data on general morbidity, family planning and vital events, but the morbidity data is not reliable because of the limitation of the interview method. This is why interviews are often combined with health examination surveys and/or laboratory measurements. An alternative method of measuring subjective phenomena is the self-administered Questionnaire, i.e., a questionnaire without an interviewer. The use of questionnaires is simpler and cheaper, and they may be sent, for example, by mail to persons sampled from a given target population. A certain level of education, and skill is expected from the respondents when a questionnaire is administered. There is usually a high rate of non-response. Health records survey involves collection of data from health service records. This is obviously the cheapest method of collecting data. This method has several disadvantages:

(a) the estimates obtained from the records are not population-based;
(b) reliability of data is open to question, and
(c) lack of uniform procedures and standardization in the recording of data.

Unless the aim of the survey is to derive information from a special group (e.g., school children or a particular occupational group), the household is the most common sampling unit. It is one that allows for the collection of most social, economic and health information in a convenient way. National Family Health Survey and District Level Health Survey are some of the examples.

The size of the sample, necessary for a household survey, depends upon the measurement being taken and the degree of precision needed. Many national samples typically cover between 5,000 to 10,000 households. This is usually considered adequate for providing national estimates on such variables as health care status, anthropometric measurements, food consumption, income, expenditure, housing, literacy, etc. (7).

Surveys carried out by either single or repeat visits provide direct estimates of certain events. A single survey obtains the necessary information retrospectively and is subject to problems of recall and omission. Follow-up surveys on the same households within short intervals (e.g., 6 months) appear to provide more accurate estimates of events but may be too expensive for monitoring purposes.

Data must be gathered under standardized conditions with quality control. The collection of data should be limited to those items for which there is a clearly defined use or need; the fact that data might be of interest or use to someone, someday, somewhere is not a valid reason for collecting them (16). The data that is collected should be transformed into information by reducing them, summarizing them and adjusting them for variations in the age and sex composition of the population so that comparisons over time and place are possible.

13. Other routine statistics related to health

The following list, which is not comprehensive, merely serves to give examples of sources of data that have already been mentioned:

(1) Demographic: In addition to routine census data, statistics on such other demographic phenomena as population density, movement and educational level.

(2) Economic: Consumption of such consumer goods as tobacco, dietary fats and domestic coal; sales of drugs and remedies; information concerning per capita income, employment and unemployment data.

(3) Social security schemes: Medical insurance schemes make it possible to study the occurrence of illnesses in the insured population. Other useful data comprise sickness absence, sickness and disability benefit rates.

14. Non-quantifiable information

Hitherto, the health information system concentrated mainly on quantifiable (statistical) data. Health planners and decision makers require a lot of non-quantifiable information, for instance, information on health policies, health legislation, public attitudes, programme costs, procedures and technology. In other words, a health information system has multi-disciplinary inputs. There should be proper storage, processing and dissemination of information.

ELEMENTARY STATISTICAL METHODS

In any field of inquiry or investigation, data is first obtained which is subsequently classified, analysed and tested for accuracy by statistical methods. Data that is obtained directly from an individual is called primary data. The census of 1991 is an example of collecting primary data relating to the population. The collection of data about the health and sickness of a population is primary data. Data that is obtained from outside source is called secondary data. If we are studying the hospital records and want to use
the census data, the census data becomes secondary data. Primary data gives the precise information wanted which the secondary data may not give.

Presentation of Statistical Data

Statistical data, once collected, must be arranged purposefully, in order to bring out the important points clearly and strikingly. Therefore the manner in which statistical data is presented is of utmost importance. There are several methods of presenting data — tables, charts, diagrams, graphs, pictures and special curves. A brief description of these methods is given below:

**TABULATION**

Tables are devices for presenting data simply from masses of statistical data. Tabulation is the first step before the data is used for analysis or interpretation. A table can be simple or complex, depending upon the number or measurement of a single set or multiple sets of items. Whether simple or complex, there are certain general principles which should be borne in mind in designing tables: (a) The tables should be numbered e.g., Table 1, Table 2, etc. (b) A title must be given to each table. The title must be brief and self-explanatory, (c) The headings of columns or rows should be clear and concise, (d) The data must be presented according to size or importance; chronologically, alphabetically or geographically, (e) If percentages or averages are to be compared, they should be placed as close as possible. (f) No table should be too large, (g) Most people find a vertical arrangement better than a horizontal one because, it is easier to scan the data from top to bottom than from left to right, (h) Foot notes may be given, where necessary, providing explanatory notes or additional information. Some examples of tabulation are given below:

1. **Simple tables**

<table>
<thead>

</tr>
<tr>
<td>1941</td>
</tr>
<tr>
<td>1951</td>
</tr>
</tbody>
</table>

*Source: Census of India, 2011

2. **Frequency distribution table**

In a frequency distribution table, the data is first split up into convenient groups (class intervals) and the number of items (frequency) which occur in each group is shown in the adjacent column. Example: The following figures are the ages of patients admitted to a hospital with poliomyelitis. Construct a frequency distribution table.

8, 24, 38, 5, 6, 12, 4, 3, 2, 3, 23, 9, 18, 16, 1, 2, 3, 5, 11, 13, 5, 9, 11, 17, 10, 6, 5, 16, 20, 4, 3, 3, 10, 3, 2, 1, 6, 9, 3, 7, 14, 8, 1, 4, 6, 4, 15, 22, 2, 1, 4, 7, 1, 12, 3, 23, 4, 19, 6, 2, 2, 4, 14, 23, 21, 3, 2, 9, 3, 2, 1, 7, 19

The data given above may be conveniently analyzed as shown below:

<table>
<thead>
<tr>
<th>Age group</th>
<th>Frequency</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-4</td>
<td>35</td>
</tr>
<tr>
<td>5-9</td>
<td>18</td>
</tr>
<tr>
<td>10-14</td>
<td>11</td>
</tr>
<tr>
<td>15-19</td>
<td>8</td>
</tr>
<tr>
<td>20-24</td>
<td>6</td>
</tr>
</tbody>
</table>

The data, analyzed above, is prepared in the form of a frequency table as shown below:

<table>
<thead>
<tr>
<th>Age group</th>
<th>Number of Patients</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-4</td>
<td>35</td>
</tr>
<tr>
<td>5-9</td>
<td>18</td>
</tr>
<tr>
<td>10-14</td>
<td>11</td>
</tr>
<tr>
<td>15-19</td>
<td>8</td>
</tr>
<tr>
<td>20-24</td>
<td>6</td>
</tr>
</tbody>
</table>

In the above example, the age is split into groups of five. These are known as class intervals. The number of observations in each group is called frequency. In constructing frequency distribution tables, the questions that arise are: Into how many groups the data should be split? And what class interval should be chosen? As a practical rule, it might be stated that when there is large data, a maximum of 20 groups, and when there is not much data, a minimum of 5 groups, could be conveniently taken. As far as possible, the class intervals should be equal, so that observations could be compared. The merits of a frequency distribution table are, that it shows as a glance how many individual observations are in a group, and where the main concentration lies. It also shows the range, and the shape of distribution.

**CHARTS AND DIAGRAMS**

Charts and diagrams are useful methods of presenting simple statistical data. They have a powerful impact on the imagination of people. Therefore, they are a popular media of expressing statistical data, especially in newspapers and magazines. The impact of the picture depends on the way it is drawn. A few general remarks need be mentioned about charts and diagrams. Diagrams are better retained in the memory than statistical tables. The data that is to be presented by diagrams ought to be simple. Then there is no risk that the reader will misunderstand. However, simplicity may be retained only at the expense of details and accuracy. That is, lot of details of the original data may be lost in the charts and diagrams. If we want the real study, we have to go back to the original data.

1. **Bar charts**

Bar charts are merely a way of presenting a set of numbers by the length of a bar — the length of the bar is proportional to the magnitude to be represented. Bar charts are a popular media of presenting statistical data because they are easy to prepare, and enable values to be compared visually. The following are some examples of bar charts.
(a) SIMPLE BAR CHART
Bars may be vertical or horizontal (Fig. 1 and Fig. 2). The bars are usually separated by appropriate spaces with an eye to neatness and clear presentation. A suitable scale must be chosen to present the length of the bars.

![IMAGE 1]

**FIG. 1**
India; Sex Ratio 1901-2001

(c) COMPONENT BAR CHART
The bars may be divided into two or more parts ... each part representing a certain item and proportional to the magnitude of that particular item (Fig. 4).

![IMAGE 2]

**FIG. 4**
India: Growth of population 1901 to 2011

(b) MULTIPLE BAR CHART
Fig. 3 gives an example of a multiple bar chart or a compound bar chart. Two or more bars can be grouped together. In Fig. 3, population and land area by region are compared.

![IMAGE 3]

**FIG. 3**
Population and land area by Region.

2. Histogram
It is a pictorial diagram of frequency distribution. It consists of a series of blocks (Fig. 5). The class intervals are given along the horizontal axis and the frequencies along the vertical axis. The area of each block or rectangle is proportional to the frequency. Fig. 5 is the histogram of the frequency distribution of blood pressure in females 45-64 years.

![IMAGE 4]

**FIG. 5**
Frequency distribution of diastolic blood pressure in females aged 45-64 years.

**FREQUENCY POLYGON**
A frequency distribution may also be represented diagrammatically by the frequency polygon. It is obtained by joining the mid-points of the histogram blocks. Fig. 6 is the frequency polygon of the distribution of readings of systolic blood pressure in a community.

![IMAGE 5]
the percentages in the segments (Fig. 8) as it may not be sometimes very easy, virtually, to compare the areas of segments.

![World population](image)

**Fig. 8**

4. **Pictogram**

Pictograms are a popular method of presenting data to the "man in the street" and to those who cannot understand orthodox charts. Small pictures or symbols are used to present the data. For example, a picture of doctor to represent the population per physician (Fig. 9). Fractions of the picture can be used to represent numbers smaller than the value of a whole symbol. In essence, pictograms are a form of bar charts.

**STATISTICAL MAPS**

When statistical data refer to geographic or administrative areas, it is presented either as "Shaded Maps" or "Dot maps," according to suitability. The shaded maps are used to present data of varying size. The areas are shaded with different colours, or different intensities of the same colour, which is indicated in the key.

Scatter diagrams shows the relationship between two variables, e.g., Fig. 10 shows a positive correlation between the intakes of fat and sugar in the average diets of 41 countries. Populations with more income are known to consume more protein, fat and also sugar (Source: Yudkin, J., (1964): Lancet, 2, 5).

![Population per physician](image)

**Fig. 9**

3. **Pie charts**

Instead of comparing the length of a bar, the areas of segments of a circle are compared. The area of each segment depends upon the angle. Pie charts are extremely popular with the layman, but not with statisticians who consider them inferior to bar charts. It is often necessary to indicate

![Pie chart](image)

**Fig. 7**

The text is a statistical analysis and presentation involving data tables and graphs. Here is the natural text representation:

**STATISTICAL AVERAGES**

The word "average" implies a value in the distribution, around which the other values are distributed. It gives a mental picture of the central value. There are several kinds of averages, of which the commonly used are: (1) The Arithmetic Mean, (2) Median, and (3) The Mode.

**The Mean**

The arithmetic mean is widely used in statistical calculation. It is sometimes simply called Mean. To obtain the mean, the individual observations are first added together, and then divided by the number of observations. The operation of adding together is called 'summation' and is denoted by the sign $\Sigma$ or S. The individual observation is denoted by the sign $x_i$ and the mean is denoted by the sign $\bar{x}$ (called "X bar").

The mean ($\bar{x}$) is calculated thus: the diastolic blood pressure of 10 individuals was 84, 75, 81, 79, 71, 95, 75, 77, 74, 90. The total was 810. The mean is 810 divided by 10 which is 81.0.

The advantages of the mean are that it is easy to calculate and understand. The disadvantages are that sometimes it may be unduly influenced by abnormal values in the distribution. Sometimes it may even look ridiculous; for instance, the average number of children born to a woman in a certain place was found to be 4.76, which never occurs in reality. Nevertheless, the arithmetic mean is by far the most useful of the statistical averages.

**The Median**

The median is an average of a different kind, which does not depend upon the total and number of items. To obtain the median, the data is first arranged in an ascending or descending order of magnitude, and then the value of the middle observation is located, which is called the median. For example, the diastolic blood pressure of 9 individuals was as follows: (Fig. 11)

The median is 79, which is the value of the middle observation (Fig. 12).
MEASURES OF DISPERSION

The daily calorie requirement of a normal adult doing sedentary work is laid down as 2,400 calories. This clearly is not universally true.

There must be individual variations. If we examine the data of blood pressure or heights or weights of a large group of individuals, we will find that the values vary from person to person. Even within the same subject, there may be variation from time. The questions that arise are: What is normal variation? And how to measure the variation?

There are several measures of variation (or "dispersion" as it is technically called) of which the following are widely known:

(a) The Range
(b) The Mean or Average Deviation
(c) The Standard Deviation

(a) The Range

The range is by far the simplest measure of dispersion. It is defined as the difference between the highest and lowest figures in a given sample. For example, from the following record of diastolic blood pressure of 10 individuals:

83, 75, 81, 79, 71, 90, 75, 95, 77, 94.

It can be seen that the highest value was 95 and the lowest 71. The range is expressed as 71 to 95 or by the actual difference (24). If we have grouped data, the range is taken as the difference between the mid-points of the extreme categories. The range is not of much practical importance, because it indicates only the extreme values between the two values and nothing about the dispersion of values between the two extreme values.

(b) The Mean Deviation

It is the average of the deviations from the arithmetic mean. It is given by the formula:

\[ M.D. = \frac{\sum |x - \bar{x}|}{n} \]

Example: The diastolic blood pressure of 30 individuals was as follows: 83, 75, 81, 79, 71, 95, 75, 77, 84 and 90. Find the mean deviation.

**Answer (Mean deviation)**

</tbody>
</table>

\[ \bar{x} = 81, \quad \eta = 10, \quad \text{Total} = 810 \]

\[ \frac{\text{Mean}}{10} = 81, \quad \text{The Mean Deviation} = \frac{56}{10} = 5.6 \]

(c) The Standard Deviation

The standard deviation is the most frequently used measure of deviation. In simple terms, it is defined as "Root - Means - Square - Deviation." It is denoted by the Greek letter sigma \( \sigma \) or by the initials S.D. The standard deviation is calculated from the basic formula:

\[ \text{S.D.} = \sqrt{\frac{\sum (x - \bar{x})^2}{n}} \]

When the sample size is more than 30, the above basic formula may be used without modification. For smaller samples, the above formula tends to underestimate the standard deviation, and therefore needs correction, which is done by substituting the denominator \((n-1)\) for \(n\). The modified formula \(s\) as follows:

\[ s = \sqrt{\frac{\sum (x - \bar{x})^2}{n-1}} \]

The steps involved in calculating the standard deviation are as follows:

(a) First of all, take the deviation of each value from the arithmetic mean.

\[ x - \bar{x} \]

(b) Then, square each deviation.

\[ (x - \bar{x})^2 \]

(c) Add up the squared deviations.

\[ \Sigma (x - \bar{x})^2 \]

(d) Divide the result by the number of observations \(n\):

\[ \frac{\Sigma (x - \bar{x})^2}{n} \]

(e) Then take the square root, which gives the standard deviation.

Example: The diastolic blood pressure of 10 individuals was as follows: 83, 75, 81, 79, 71, 95, 75, 77, 84 and 90. Calculate the standard deviation.

<table>
<thead>
<tr>
<th>x</th>
<th>(x - \bar{x})</th>
<th>(x - \bar{x})^2</th>
</tr>
</thead>
<tbody>
<tr>
<td>83</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>75</td>
<td>-6</td>
<td>36</td>
</tr>
<tr>

<td>0</td>
<td>0</td>
</tr>
<tr>
<td>79</td>
<td>-2</td>
<td>4</td>
</tr>
<tr>
<td>71</td>
<td>-10</td>
<td>100</td>
</tr>
<tr>
<td>95</td>
<td>14</td>
<td>196</td>
</tr>
<tr>
<td>75</td>
<td>-6</td>
<td>36</td>
</tr>
<tr>
<td>77</td>
<td>-4</td>
<td>16</td>
</tr>
<tr>
<td>84</td>
<td>3</td>
<td>9</td>
</tr>
<tr>
<td>90</td>
<td>9</td>
<td>81</td>
</tr>
</tbody>
</table>

\[ \bar{x} = 81, \quad \eta = 10, \quad \text{Total} = 842 \]

\[ \text{S.D.} = \sqrt{\frac{\Sigma (x - \bar{x})^2}{n}} = \sqrt{\frac{482}{10-1}} = \sqrt{\frac{482}{9}} = \sqrt{53.55} = 7.31 \]

The meaning of standard deviation can only be appreciated fully when we study it with reference to what is described as normal curve. For the present, we may contend
NORMAL DISTRIBUTION

The normal distribution or 'normal curve' is an important concept in statistical theory. Let us suppose, we collect the haemoglobin values of a very large number of people and make a frequency distribution with narrow class intervals, we are likely to get a smooth, symmetrical curve. Such a curve is called a normal distribution or normal curve. The shape of the curve will depend upon the mean and standard deviation which in turn will depend upon the number and nature of observations. It follows, therefore, there will be an infinite number of normal curves.

It is useful to note at this stage that in a normal curve (Fig. 15) : (a) the area between one standard deviation on either side of the mean (x ± 1 σ) will include approximately 68.27 per cent of the values in the distribution, (b) the area between two standard deviations on either side of the mean (x ± 2 σ) will cover most of the values, i.e., approximately 95 per cent of the values, and (c) the area between (x ± 3 σ) will include 99.73 per cent of the values. These limits on either side of the mean are called 'confidence limits' and are as shown in Fig. 15.

Supposing we are considering the 95 per cent confidence limits (x ± 2 σ). When we say this, we mean that 95 per cent of the area of the normal curve, and hence 95 per cent of the values in the distribution will be included between the limits x ± 2 σ. Therefore, the probability of a reading falling outside the 95 per cent confidence limits is 1 in 20 (P = 0.05).

FIG. 15
Normal curve

Standard normal curve

Although there is an infinite number of normal curves depending upon the mean and standard deviation, there is only one standardized normal curve, which has been devised by statisticians to estimate easily the area under the normal curve, between any two ordinates. The standard normal curve is a smooth, bell-shaped, perfectly symmetrical curve, based on an infinitely large number of observations. The total area of the curve is 1; its mean is zero; and its standard deviation is 1. The mean, median and mode all coincide. The distance of a value (x) from the mean (x) of the curve in units of standard deviation is called "relative deviate or standard normal variate" and is usually denoted by Z. The standard normal deviate or Z is given by the formula:

\[ Z = \frac{x - \mu}{\sigma} \]

A random variable (x) is said to have been standardized when it has been adjusted so that its mean is zero and its standard deviation is 1. Standardization can be effected by subtracting the mean of x, from x and dividing the resulting difference by σ, the standard deviation of x. Thus \[ \frac{x - \mu}{\sigma} \] is a standardized variable. An important concept of mathematical statistics is that the new variate "Z" like the variate "x" also follows a normal distribution. The mean of the transformed distribution is zero (0), and the standard deviation (σ) is 1.

Areas under the standard normal curve are frequently needed. They have been computed for values of different relative deviate \[ \frac{x - \mu}{\sigma} \].

An extract of these values is given in Table 4.

Estimation of probability (Example)

Let us suppose, the pulse of a group of normal healthy males was 72, with a standard deviation of 2. What is the probability that a male chosen at random would be found to have a pulse of 80 or more?

The relative deviate (Z) \[ Z = \frac{x - \mu}{\sigma} \]

\[ = \frac{80 - 72}{2} = 4 \]

The area of the normal curve corresponding to a deviate 4=0.49997 (Table 4). Since we are dealing with only half the total area (i.e., 0.5) the area beyond 0.49997 is equal to 0.5 - 0.49997 or 0.0003. Therefore, the probability is that only 3 out of 100,000 individuals would likely have a pulse rate of 80 or higher.

SAMPLING

When a large proportion of individuals or items or units have to be studied, we take a sample. It is easier and more economical to study the sample than the whole population or universe. Great care therefore is taken in obtaining a sample. It is important to ensure that the group of people or items included in the sample are representative of the whole population to be studied.
The Sampling frame
Once the universe has been defined, a sampling frame must be prepared. A sampling frame is a listing of the members of the universe from which the sample is to be drawn. The accuracy and completeness of the sampling frame influences the quality of the sample drawn from it.

Sampling Methods
The following three methods are most commonly used:

1) Simple random sample: This is done by assigning a number to each of the units (the individuals or households) in the sampling frame. A table of random numbers is then used (see page 850) to determine which units are to be included in the sample. Random numbers are a haphazard collection of certain numbers, arranged in a random manner to eliminate personal selection of unconscious bias in taking out the sample. With this procedure, the sample is drawn in such a way that each unit has an equal chance of being drawn in the sample. This technique provides the greatest number of possible samples.

2) Systematic random sample: This is done by picking every 5th or 10th unit at regular intervals. For example, to carry out a file survey in a town, we take 10 per cent sample. The houses are numbered first. Then a number is selected at random between 1 and 10 (say four). Then every 10th number is selected from that point on 4, 14, 24, 34, etc. By this method, each unit in the sampling frame would have the same chance of being selected, but the number of possible sample is greatly reduced.

3) Stratified random sample: The sample is deliberately drawn in a systematic way so that each portion of the sample represents a corresponding strata of the universe. This method is particularly useful where one is interested in analysing the data by a certain characteristic of the population, viz, Hindus, Christians, Muslims, age-groups etc. – as we know these groups are not equally distributed in the population.

It is useful to note at this stage that Greek letters are usually used to refer to population characteristics: mean (μ), standard deviation (σ), and Roman letters to indicate sample characteristics: mean (X̄), standard deviation (s).

Sampling Errors
If we take repeated samples from the same population or universe, the results obtained from one sample will differ to some extent from the results of another sample. This type of variation from one sample to another is called sampling error. It occurs because data were gathered from a sample rather than from the entire population of concern. Presuming that the sampling procedure is such that all the individuals in the population are invited equally to come to the sample, the factors that influence the sampling error are: 
(a) the size of the sample and (b) the nature and variability of the individual readings. As the size of the sample increases, sampling error will decrease. As the individual readings vary widely from one another, we get more variability from one sample to another.

Non-Sampling Errors
The sampling error is not the only error which arises in a sample survey. Errors may occur due to inadequately calibrated instruments, due to observer variation, as well as due to incomplete coverage achieved in examining the subjects selected and concept errors. These are often more important than the sampling errors.

Standard Error
If we take a random sample (n) from the population, and similar samples over and over again we will find that every sample will have a different mean (X̄). If we make a frequency distribution of all the sample means drawn from the same population, we will find that the distribution of the mean is nearly a normal distribution and the mean of the sample means practically the same as the population mean (μ). This is a very important observation that the sample means are distributed normally about the population mean (μ). The standard deviation of the means is a measure of the sample error and is given by the formula σ/√n which is called the standard error or the standard error of the mean. Since the distribution of the means follows the pattern of normal distribution, it is not difficult to visualise that 95 percent of the sample means will lie within limits of two standard error (μ ± 2σ/√n) on either side of the true or population mean. Therefore standard error (S.E.), is a measure which enables us to judge whether the mean of a given sample is within the set confidence limits or not.

TESTS OF SIGNIFICANCE
We have observed till now that standard error indicates how reliable an estimate of the mean is likely to be. The concept of standard error is applied with appropriate formulae to all statistics, i.e., mean, standard deviation, etc. It is proposed to consider briefly the following:

(a) Standard Error of the Mean
(b) Standard Error of Proportion
(c) Standard Error of Differences
(d) Standard Error of Differences between two Proportions.

(a) Standard Error of the Mean
We have already considered in some detail the meaning of the "standard error of the mean" which is also called simply the standard error, and the distribution of the sample means about the true mean of the universe. In actual practice, we don't take repeated samples usually from a population. We take only one sample from the universe and calculate the mean and standard deviation. The questions that arise are: How accurate is the mean of our sample? What can be said about the true mean of the universe? In order to answer these questions, we calculate the standard error of the mean and set up confidence limits within which the mean (μ), of the population (of which we have only one sample) is likely to lie.

Example: Let us suppose, we obtained a random sample of 25 males, age 26–24 years whose mean temperature was 98.14 deg. F with a standard deviation of 0.6. What can we say of the true mean of the universe from which the sample was drawn?

We use the standard error as the yard stick:

\[ S.E. = \frac{S}{\sqrt{n}} = \frac{0.6}{\sqrt{25}} = 0.12 \]

We now set up confidence limits on the basis of the normal curve distribution. If the limits are set out at twice the standard error from the mean (95 per cent confidence limits) the range of the population mean would be 98.14 ± 2(0.12) = 97.90 deg. F. to 98.38 deg. F. The chances will be only 1 in 20 (P = 0.05) that the population mean would be outside these limits.

Very often we come across in scientific terminology the word "significant". When we say that "this difference is
significant", we mean that it is unlikely to be merely due to chance. It has become customary to regard as significant, when \( P < 0.01 \) (1 in 100) and more significant, when \( P < 0.001 \) (1 in 100).

(b) Standard Error of Proportion

Let us suppose, the proportion of males in a certain village was 52 per cent. A random sample of 100 people was taken, and the proportion of males was found to be 40 per cent. What conclusions could be drawn from the sample? What possible range of males could we expect in a sample of 100, within 95 per cent confidence limits?

In an example of this kind, we are not dealing with means but with proportions in a sample and its universe. We may designate these proportions as \( p \) and \( q \) and proceed to calculate the standard deviation round that expected 52 per cent. This is called the standard error of proportion and is given by the formula:

\[
\text{Standard Error of Proportion} = \sqrt{\frac{pq}{n}}
\]

where \( p \) = proportion of males; \( q \) = proportion of females and \( n \) = size of the sample. Substituting the values, we get:

\[
\text{S.E. (Proportion)} = \sqrt{\frac{52 \times 48}{100}} = 5.0
\]

We take two standard errors on either side of 52 as our criterion. That is, if the sample is a truly representative one, we might get by chance a value in the range 52 - 2 (5) = 62 and 52 - 2 (5) = 42. In other words, the proportion of males in our sample could vary from 42 to 62. Since the observed proportion of males was only 40 per cent and well outside the confidence limits, we consider the difference between the observed and expected values "significant" and is not likely to have arisen by chance. The relative deviation in this particular case, in units of a standard error of \( \frac{52}{n} \), will be:

\[
\text{Relative Deviation} = \frac{52 - 40}{5} = 2.4
\]

Since the relative deviation exceeded 2, it is obvious in the present example, that the deviation was "significant". This significance test is applicable in situations where the population consists of only 2 classes or proportions, e.g., males and females, sick and healthy, successes and failures, etc.

(c) Standard Error of Difference Between Two Means

Very often, in biological work the investigator is faced with the problem of comparing results between two groups. One may be the control group and the other experimental group. The question arises, whether the difference between the means of the two groups is significant to indicate that the samples represent two different universes. We proceed to tackle this problem by calculating the standard error of difference between the two means.

Let us suppose, we are testing the effect of a drug on mice. 24 mice, comparable in all respects, were randomly divided into 2 groups. Group A was the control group, i.e., no treatment. The other group, the experimental group was given a drug for a certain period of time. At the end of the experiment, the mice were sacrificed and the kidney of each animal was weighed in milligrams. The effects of the treatment on the kidney weights was as follows:

<table>
<thead>
<tr>
<th></th>
<th>Number</th>
<th>Mean</th>
<th>Standard Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control group</td>
<td>12</td>
<td>318</td>
<td>10.2</td>
</tr>
<tr>
<td>Experimental group</td>
<td>12</td>
<td>370</td>
<td>24.1</td>
</tr>
</tbody>
</table>

Let us determine whether the difference between the kidney weights of the two groups is significant.

We apply the formula for the standard error of difference between the two means:

\[
\text{S.E. (d)} = \sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}} = \sqrt{\frac{10.2^2}{12} + \frac{24.1^2}{12}} = \sqrt{8.67 + 48.4} = \sqrt{57.07} = 7.5
\]

The standard error of difference between the two means is 7.5. The actual difference between the two means is (370 - 318) = 52, which is more than twice the standard error of difference between the two means, and therefore "significant". We conclude that the treatment affected the kidney weights.

(d) Standard Error of Difference Between Proportions

Instead of means, sometimes we may have to test the significance of difference between two proportions or ratios to find out if the difference between the two proportions or ratios have occurred by chance. In this case, we calculate the standard error of difference between two proportions:

\[
\text{Confidence limits} \quad \text{Normal deviate (N.D.)} = \frac{x - \mu}{\sigma/\sqrt{n}} \quad \text{Significance}
\]

<table>
<thead>
<tr>
<th></th>
<th>N.D. &gt; 2</th>
<th>( P &lt; 0.05 )</th>
<th>Significant at 5 per cent level</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \mu ) is outside the 95 per cent confidence limits</td>
<td>N.D. &gt; 2</td>
<td>( P &lt; 0.05 )</td>
<td>Significant at 5 per cent level</td>
</tr>
<tr>
<td>( \mu ) is just within 95 per cent confidence limits</td>
<td>N.D. = 2</td>
<td>( P = 0.05 )</td>
<td>Just significant at 5 per cent level</td>
</tr>
<tr>
<td>( \mu ) is within the 95 per cent confidence limits</td>
<td>N.D. &lt; 2</td>
<td>( P &gt; 0.05 )</td>
<td>Not significant at 5 per cent level</td>
</tr>
</tbody>
</table>
Let us suppose, we are making a trial of 2 whooping cough vaccines. The results of the field trial were as follows:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stated</td>
<td>2,400</td>
<td>3,300</td>
</tr>
<tr>
<td>Achieved</td>
<td>90</td>
<td>86</td>
</tr>
<tr>
<td>From the above it appears that vaccine B is superior to vaccine A. Is there any significance?</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

We calculate the standard error of difference between the two proportions:

\[
\text{S.E. of Difference between two proportions} = \sqrt{\frac{p_A q_A}{n_A} + \frac{p_B q_B}{n_B}}
\]

\[
= \sqrt{\frac{0.036 \times 0.97}{22} + \frac{0.036 \times 0.97}{86}}
\]

\[
= \sqrt{24.4 \times 75.6 + 162 \times 83.8} = 30.44 + 28.86 = 0.3622
\]

The standard error of difference is 6 whereas the observed difference (24 - 16.2) was 8.2. In other words, the observed difference between the two groups is less than twice the S.E. of difference, i.e., 2 x 6. We infer that there was no strong evidence of any difference between the efficacy of the two vaccines. Therefore, the observed difference might be easily due to chance.

Alternatively, we can use the CHI-SQUARE (χ²) Test in an example of this kind.

**CHI-SQUARE TEST**

Chi-square (χ²) Test offers an alternate method of testing the significance of difference between two proportions. It has the advantage that it can also be used when more than two groups are to be compared.

Let us consider the previous example: we were making a trial of 2 whooping cough vaccines. The results of the field trial were as follows:

<table>
<thead>
<tr>
<th>Vaccine</th>
<th>Attacked</th>
<th>Not Attacked</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>22</td>
<td>68</td>
<td>90</td>
</tr>
<tr>
<td>B</td>
<td>14</td>
<td>72</td>
<td>86</td>
</tr>
</tbody>
</table>

Apparantly, vaccine B was superior to vaccine A. The question that arises is whether the vaccine B was really superior to vaccine A, or whether the difference was merely due to chance.

(1) TEST THE 'NULL HYPOTHESIS'

First, we set up a hypothesis, called the Null Hypothesis that there was no difference between the effect of the two vaccines, and then proceed to test the hypothesis in quantitative terms. It is done in the following manner:

We first pool the results from the two vaccines. The proportion of people attacked will be 36/176 = 0.204. The proportion of people not attacked will be 146/176 = 0.8. From these proportions, we now calculate the expected number of attacks or cases, and those not attacked. The expected number of attacks by vaccine A will be 90 x 0.204 = 18.36; the expected number not attacked will be 90 x 0.795 = 71.55. Similarly, the expected number of attacks by vaccine B will be 86 x 0.204 = 17.54; the expected number not attacked will be 86 x 0.795 = 68.37. We shall now rewrite the previous table, showing the observed (O) and expected (E) values in each cell:

A    | O = 22 | E = 18.36 |
-----|--------|-----------|
      | 18.36  | 3.64      |
      | 3.55   |
B    | O = 14 | E = 17.54 |
-----|--------|-----------|
      | 17.54  | 3.49      |
      | 3.63   |

(2) APPLYING THE χ² TEST

\[
\chi^2 = \sum \frac{(O - E)^2}{E}
\]

\[
\chi^2 = \frac{(3.64)^2}{18.36} + \frac{(3.55)^2}{18.36} + \frac{(3.49)^2}{17.54} + \frac{(3.63)^2}{17.54} = 0.72 + 0.17 + 0.71 + 0.19 = 1.79
\]

(3) FINDING THE DEGREE OF FREEDOM

The next step in the calculation is to find out what is known as the degree of freedom (d.f.). This depends upon the number of columns and rows in the original table, and given by the formula:

\[
d.f. = (c - 1)(r - 1)
\]

where c = Number of columns

r = Number of rows

In our table (cited above), there are two rows (attack and not attacked) and two columns (vaccine A and vaccine B). It is a 2 x 2 contingency table. The degree of freedom will be:

\[
d.f. = (c - 1)(r - 1) = (2 - 1)(2 - 1) = 1
\]

(4) PROBABILITY TABLES

We next turn to the published probability tables given below. On referring to χ² Table, with 1 degree of freedom, the value of χ² for a probability of 0.05 is 3.84. Since the observed value (1.79) is much lower we conclude that the null hypothesis is true and that vaccine B is not superior to vaccine A. The test is valid only if the expected number in each cell is not less than two.

**CORRELATION AND REGRESSION**

**Meaning of Correlation**

Often we wish to know whether there is linear relation between two variables, e.g., height and weight, temperature and pulse, age and vital capacity, etc. In order to find out whether there is significant association or not between two variables (we may call them x and y), we calculate what is known as Co-efficient of Correlation, which is represented by the symbol r.

Suppose, we have 2 variables x and y, and we have n individuals who have each one reading of x and one reading of y. The correlation coefficient is given by the formula:

\[
r = \frac{\Sigma (x - \bar{x})(y - \bar{y})}{\sqrt{\Sigma (x - \bar{x})^2 \Sigma (y - \bar{y})^2}}
\]
The correlation coefficient $r$ tends to lie between $-1.0$ and $+1.0$. If $r$ is near $+1$, it indicates a strong positive association between $x$ and $y$, i.e., when one variable increases the other variable also increases. A value near $-1$ indicates a strong negative association i.e. when one variable increases the other decreases. If $r = 0$, it indicates there's no association between $x$ and $y$. There are tests to show whether or not the correlation could be due to chance. However, it needs to be noted that correlation does not necessarily prove causation.

### Meaning of Regression

If we wish to know in an individual case the value of one variable, knowing the value of the other, we calculate what is known as the regression coefficient of one measurement to the other. It is customary to denote the independent variable by $x$ and the dependent variable by $y$. The formula for obtaining the regression coefficient is as follows:

$$ y = y' + b (x - X) $$

where

$$ y' = \text{mean of } y, \ y_1, \ y_2, \ldots, \ y_5 $$

$$ x' = \text{mean of } x, \ x_1, \ x_2, \ldots, \ x_5 $$

$$ b = \frac{\sum (x - X) (y - Y)}{\sum (x - X)^2} $$

The value of $b$ is called the regression coefficient of $y$ upon $x$. Similarly, we can obtain the regression of $x$ upon $y$.

$$ x = \bar{x} + b' (y - Y) $$

$$ b' = \frac{\sum (x - X) (y - Y)}{\sum (y - Y)^2} $$

Where $b'$ is the regression coefficient of $x$ upon $y$. The function of regression is to provide a means of estimating the value of one variable from the value of the other.

### References

Communication can be regarded as a two-way process of exchanging or shaping ideas, feelings and information. Broadly it refers "to the countless ways that humans have of keeping in touch with one another" (1).

Communication is more than mere exchange of information. It is a process necessary to pave way for desired changes in human behaviour, and informed individual and community participation to achieve predetermined goals. Communication has, in recent years, developed into an interdisciplinary science drawing richly from social sciences. With the development of newer methods of communication and information explosion, the mental development of the humans has expanded considerably for clearer thinking, better social inter-sectoral coordination.

Communication and education are interwoven. Communication strategies can enhance learning. The ultimate goal of all communication is to bring about a change in the desired direction of the person who receives the communication. This may be at the cognitive level in terms of increase in knowledge; it may be affective in terms of changing existing patterns of behaviour and attitudes; and it may be psychomotor in terms of acquiring new skills. These are referred to as learning objectives (2).

Communication is part of our normal relationship with other people. Our ability to influence others depends on our communication skills, e.g., speaking, writing, listening, reading and reasoning. These skills are much needed in health education. The developing countries are now beginning to exploit the current "communication revolution" to put today's health information at the disposal of families, to help people to achieve health by their own actions and efforts. It is said that without communication an individual could never become a human being, without mass communication, he could never become a part of modern society (3).

---

**THE COMMUNICATION PROCESS**

Communication which is the basis of human interaction is a complex process. It has the following main components (Fig. 1):

1. **Sender**
   - his objectives, clearly defined
   - his audience: it's interest and needs
   - his message
   - channels of communication
   - his professional abilities and limitations

The impact of the message will depend on his own social status (authority), knowledge and prestige in the community.

1. **Receiver**

All communications must have an audience. This may be a single person or a group of people. Without the audience, communication is nothing more than mere noise. It is this element of audience and their frame of mind (e.g., opinions, attitudes, prejudices) which lends meaning to all the different types of communication.

The audience may be of two types: the controlled and the uncontrolled. A controlled audience is one which is held together by a common interest. It is a homogeneous group. An uncontrolled or "free" audience is one which has

---

**Fig. 1**

Communication process

- Awareness
- Interest
- Evaluation
- Adoption [behavior change]
gathered together from motives of curiosity. This type of audience poses a challenge to the ability of the educator. The more homogeneous the audience is, the greater are the chances of an effective communication.

3. Message
A message is the information (or “technical know-how”) which the communicator transmits to his audience to receive, understand, accept and act upon. It may be in the form of words, pictures or signs. Health communication may fail in many cases, if its message is not adequate.
A good message must be:
- In line with the objective
- Based on felt needs
- Clear and understandable
- Specific and accurate
- Timely and adequate
- Fitting the audience
- Interesting
- Culturally and socially appropriate

Transmitting the right message to the right people at the right time is a crucial factor in successful communication.

4. Channels of communication
By channel is implied the “physical bridges” or the media of communication between the sender and the receiver.

Media systems
The total communication effort is based on three media systems:

a. Interpersonal communication
b. Mass media
c. Traditional or folk media

a. Interpersonal communication
The most common channel of communication is the interpersonal or face-to-face communication. Being personal and direct it is more persuasive and effective than any other form of communication. Interpersonal communication is particularly important in influencing the decisions of the undecided persons. The superiority of interpersonal communication over mass media for creation of motivational effect has been well documented.

When the message relayed via mass media gets diffused in the community, it is picked up by the interpersonal and informal networks. The message is then subject to debate and discussion by interpersonal communications. On the basis of this scrutiny a consensus is gradually built up in the community whether to accept or reject the message.

b. Mass media
In mass communication, the channel is one or more of the following: “mass media”, viz TV, radio, printed media, etc. Mass media have the advantage of reaching a relatively larger population in a shorter time than is possible with other means. Being one-way channels of communication, mass media carry messages only from the centre to the periphery; feedback mechanisms are poorly organized. Being impersonal media, they are usually not effective in changing established modes of behaviour.

c. Folk media
Every community has its own network of traditional or folk media such as folk dances, singing, drama, Naadanit in Uttar Pradesh, Bhrinj in Andhra Pradesh and Hanika in western India besides informal group gatherings, caste or religious meetings. These are important channels of communication close to the cultural values of the rural population. They have been the principal instruments of preserving the cultural heritage. Health messages may be communicated through these traditional media.

Every channel of communication has its advantages and limitations. For instance, knowledge of surgery cannot be effectively transmitted by verbal communication, demonstrations are needed. The proper selection and use of channels results in successful communication. Since effective communication is seldom achieved through the use of one method alone, an attempt should be made to combine a variety of methods to accomplish the educational purpose. Health education uses a variety of methods to help people understand their own situations and choose actions that will improve their health.

5. Feedback
It is the flow of information from the audience to the sender. It is the reaction of the audience to the message. If the message is not clear or otherwise unacceptable the audience may reject it outright. The feedback thus provides an opportunity to the sender to modify his message and render it acceptable. In interpersonal communication the feedback is immediate. In mass communication it takes some time to get feedback. Feedback is generally obtained through opinion polls, surveys and interviews. It can rectify transmission errors.

TYPES OF COMMUNICATION

1. One-way communication (Didactic Method)
The flow of communication is “one-way” from the communicator to the audience. The familiar example is the lecture method in class rooms. The drawbacks of the didactic method are:
- knowledge is imposed
- learning is authoritarian
- little audience participation
- no feedback
- does not influence human behaviour

2. Two-way communication (Socratic method)
The Socratic method is a two-way method of communication in which both the communicator and the audience take part. The audience may raise questions, and add their own information, ideas and opinions to the subject. The process of learning is active and “democratic”. It is more likely to influence behaviour than one-way communication.

3. Verbal communication
The traditional way of communication has been by word of mouth. The advent of written and printed matter are of comparatively recent origin. Direct verbal communication by word of mouth may be loaded with hidden meanings. It is persuasive. Non-direct or written communication may not be as persuasive as the spoken word.
4. Non-verbal communication

Communication can occur even without words. It includes a whole range of bodily movements, postures, gestures, facial expressions (e.g., smile, raised eye brows, frown, staring, gazing etc.). Silence is non-verbal communication. It can speak louder than words.

5. Formal and informal communication

Communication has been classified into formal (follows lines of authority) and informal (grape-vine) communication. In formal network (e.g., gossip circles) exists in all organizations. The informal channels may be more active, if the formal channels do not satisfy to the information needs.

6. Visual communication

The visual forms of communication comprise: charts and graphs, pictograms, tables, maps, posters etc.

7. Telecommunication and internet

Telecommunication is the process of communicating over distance using electromagnetic instruments designed for the purpose. Radio, TV and internet etc. are mass communication media, while telephone and telegraph are known as point-to-point telecommunication systems. The point-to-point systems are closer to interpersonal communication. With the launching of satellites, a big explosion of electronic communication has taken place all over the world.

BARRIERS OF COMMUNICATION

Health education may often fail due to communication barriers between the educator and the community—these may be:

1. Physiological — difficulties in hearing, expression
2. Psychological — emotional disturbances, neurosis, levels of intelligence, language or comprehension difficulties.
3. Environmental — noise, immaturity, congestion
4. Cultural — illiteracy, levels of knowledge and understanding, customs, beliefs, religion, attitudes, economic and social class differences, language variations, cultural difficulties between foreigners and nationals, between urban education and the rural population.

Even when health services are readily available, the social and cultural barriers can present serious problems to the achievement of health behaviour change. These barriers should be identified and removed.

HEALTH COMMUNICATION

Health is the concern of everyone for everyone. Health communication is therefore an important area of communication. The term "health communication" is often used synonymously with health education, which itself suggests "outward and downward" communication of knowledge (6). Health education is the foundation of a preventive health care system.

Functions of health communication

Health communication has to cater to the following needs:
1. Information
2. Education
3. Motivation
4. Persuasion
5. Counseling
6. Raising morale
7. Health development
8. Organization

1. Information

The primary function of health communication is to provide scientific knowledge or information to people about health problems and how to maintain and promote health. People rarely seek such information although they have a right to know the facts about health and disease.

Information should be easily accessible to the people. Exposure to the right kind of health information can
- eliminate social and psychological barriers of ignorance, prejudice and misconceptions people may have about health matters;
- increase awareness of the point to the people that they are able to perceive their health needs; and
- influence people to the extent that unfelt needs become felt needs, and felt needs become demands.

The government, the media and health providers have an important social responsibility to provide factual and balanced health and health related information to the people and awaken their interest on the basis of which they can make informed decisions. But, the assumption that the acquisition of information will mean a change in an individual's behaviour and attitudes is fallacious. Most people make important decisions regarding their health only after much thought, perhaps over a period of time and after receiving educational contacts. The cultural values, beliefs and norms of the people influence their acceptance of health information. Correct information is a basic part of health education.

2. Education

Education of the general public is an integral part of a preventive oriented approach to health and disease problems; and, the basis of all education is communication. Education can help to increase knowledge. It is often assumed that knowledge determines attitudes and attitudes determine behaviour (7).

Health education can bring about changes in life styles and risk factors of disease. Most of the world's major health problems and premature deaths are preventable through changes in human behaviour at low cost (8). But education alone is insufficient to achieve optimum health. The target population must have access to proven preventive measures or procedures.

3. Motivation

It is the power that drive a person from within to act. One of the goals of health communication is to motivate individuals to translate health information into personal behaviour and lifestyle for their own health. Motivation includes the stages of interest, evaluation and decision making. Health communication assists the individual in passing from the state of awareness and interest to the final stage of decision making and adoption of the new idea or programme. Motivation may not be long-lasting; it may
diminish with lapse of time. The best channels of success involve programmes directed at individuals who already have some strong motivation, in patients with chronic illness or a disability, those facing acute crisis such as surgery or childbirth. This suggests that probably the quickest pay off will come in the area of patient education.

4. Persuasion
Persuasion is the art of winning friends and influencing people. It is an art that does not employ force or deliberate manipulation. The sole purpose of communication is to influence. Persuasion is "a conscious attempt by one individual to change or influence the general beliefs, understanding, values and behaviour of another individual or group of individuals in some desired way". Persuasive communication is more effective than coercion or authoritative communication. Persuasion can change life style and modify the role feelings of a person.

When persuasive communication is deliberately employed to manipulate feelings, attitudes and beliefs, it becomes "propaganda" or "brain washing" (11).

5. Counselling
Counselling is a process that can help people understand better and deal with their problems and communicate better with those with whom they are emotionally involved. It can improve and reinforce motivation to change behaviour. It can provide support at times of crisis. It helps them face up to their problems and to reduce or solve them.

Counselling is different from advising. It implies choice, not force. Advising amounts to directing people and cautioning them to do this and don’t do that. In different circumstances different people can undertake counselling. A counsellor should be able to:

- to communicate information
- to gain the trust of the people
- to listen sympathetically to people who are anxious, distressed and possibly hostile.
- to understand other person’s feelings and to respond to them in such a way that the other person can feel free to express his feelings
- to help people reduce or resolve their problems.

Thus counselling relies heavily on communication and related personal skills. Counselling is an important part of treatment, disease prevention and health promotion. It helps people to avoid illness and to improve their lives through their own efforts (9). Counselling develops positive attitudes. It is an integral part of all health care programmes.

6. Raising morale
Morale is "the capacity of a group of people (or team) to pull together persistently or consistently. Communication - vertical and horizontal, internal and external is the first step in any attempt to raise morale of the health team or a group of people."

7. Health development
Communication can play a powerful role in health development by helping to diffuse knowledge in respect of the goals of development and preparing the people for the roles expected of them. But its own role is essentially supportive (5). Judicial use of communication media can contribute to health development (10).

8. Health organization
Communication is the life and blood of an organization. There are two major directions in which communications within an organization flow. These are vertical and horizontal communications. Vertical communication can be downward or upward. Horizontal or cross communication takes place usually between equals at any level. The downward communication extends from top administrator down through the hierarchy of professionals and non-professionals to the beneficiaries or employees. The direction in which communication flows in an organization suggests the degree of freedom in the internal communication network (12).

Communication is an important dimension of health organization. It is an important means of intra – and inter-sectoral coordination.

HEALTH EDUCATION
Health education is a term commonly used and referred to by health professionals.

Definitions
Health education is indispensable in achieving individual and community health. It can help to increase knowledge and to reinforce desired behaviour patterns. But there is no single acceptable definition of health education. A variety of definitions exist. Concepts of health education as a process or an activity for inducing behavioural changes are emphasized in the following definitions:

1. Health education is the translation of what is known about health, into desirable individual and community behaviour patterns by means of an educational process (11).

2. The definition adopted by John M Last is "The process by which individuals and groups of people learn to behave in a manner conducive to the promotion, maintenance or restoration of health" (12).

3. Any combination of learning opportunities and teaching activities designed to facilitate voluntary adaptations of behaviour that are conducive to health (13).

4. The definition, adopted by the National Conference on Preventive Medicine in USA is "Health education is a process that informs, motivates and helps people to adopt and maintain healthy practices and lifestyles, advocates environmental changes as needed to facilitate this goal and conducts professional training and research to the same end" (14).

5. Health education is a part of health care that is concerned with promoting healthy behaviour (9).

Alma-Ata Declaration
The Declaration of Alma-Ata (1978) by emphasizing the need for "individual and community participation" gave a new meaning and direction to the practice of health education. The dynamic definition of health education is now as follows:

"a process aimed at encouraging people to want to be healthy, to know how to stay healthy, to do what they can individually and collectively to maintain health, and to seek help when needed" (6).

The Alma-Ata Declaration has revolutionised the concepts and aims of health education:

The modern concept of health education emphasizes on health behaviour and related actions of people.
Health education and behaviour

The behaviours to be adopted or modified may be that of individuals, groups (such as families, health professionals, organizations or institutions) or entire community. Strategies designed to influence the behaviour of individuals or groups will vary greatly depending upon the specific disease (or health problem) concerned and its distribution in the population as well as upon the characteristics and acceptability of available methods promoting or preventing the disease (or health problem). Health education can help to increase knowledge and to reinforce desired behaviour patterns.

It is clear that education is necessary, but education alone is insufficient to achieve optimum health. The target population must have access to proven preventive measures or procedures.

Changing concepts

Historically health education has been committed to disseminating information and changing human behaviour. Following the Alma-Ata Declaration adopted in 1978, the emphasis has shifted (from 6):

- Prevention of disease to promotion of healthy lifestyles;
- the modification of individual behaviour to modification of "social environment", in which the individual lives;
- community participation in community involvement and;
- promotion of individual and community "self-reliance".

Aims and objectives

The definition adopted by WHO in 1969 (15) and the Alma-Ata Declaration adopted in 1978 provide a useful basis for formulating the aims and objectives of health education, which may be stated as below:

1. to encourage people to adopt and sustain health promoting lifestyle and practices;
2. to promote the proper use of health services available to them;
3. to arouse interest, provide new knowledge, improve skills and change attitudes in making rational decisions to solve their own problems; and
4. to stimulate individual and community self-reliance and participation to achieve health development through individual and community involvement at every step from identifying problems to solving them.

The educational objectives are aimed at the group to be taught in the educational programme. The objectives flow from the health needs which have been discovered. They should be carefully unambiguously defined in terms of knowledge to be acquired, behaviour to be acquired or actions to be mastered. They must be pertinent if the programme is to be appropriate and successful.

The focus of health education is on people and on action (15). Its goal is to make realistic improvements in the basic quality of life. Many health education programmes hope, in some way, to influence behaviour or attitudes. The implication of these new concepts is that health education is as integral a part of the national health goals. The fact remains that effective health education has the potential for saving many more lives than has any one research discovery in the foreseeable future.

Role of health care providers

It is clear that education is necessary, but education alone is not sufficient to achieve optimum health. The role of health care provides opportunities for people to learn how to identify and analyze health and health related problems, and how to set their own targets and priorities.

a. provide opportunities for people to learn how to identify and analyze health and health related problems, and how to set their own targets and priorities;

b. make health and health related information easily accessible to the community;

c. indicate to the people alternative solutions for solving the health and health-related problems they have identified; and

d. people must have access to proven preventive measures.

APPROACH TO HEALTH EDUCATION

There are 4 well-known approaches to health education:

1. Regulatory approach (Managed prevention)

Regulation in the context of health education may be defined as any governmental intervention, direct or indirect, designed to alter human behaviour. Regulations may be promulgated by the State by a variety of administrative agencies. Regulations may take many forms ranging from prohibitions to imprisonment.

The coercive or regulatory approach seeks change in health behaviour and improvement in health through a variety of external control or laws placed on people, as for example the Child Marriage Restraint Act in India and the use of compulsory seat belts in the western countries. The legislative approach may seem to be simplest and quickest way to improve health or bring about desired changes in society, but there are also important failures of laws, e.g., prohibition of alcohol.

The reasons for the failure of the coercive approach are not far to seek: in the first place, the cause of disease (medical or social) cannot be eradicated by legislation, at the most the government can make laws to prevent a person spreading disease in his community, as for example vaccination in an emergency. Secondly in areas involving personal choice (e.g., diet, exercise, smoking) no government can pass legislation to force people to eat a balanced diet or not to smoke. It amounts to taking away some of the rights of the individual. The disastrous sterilization campaign of 1976 in India which led to the Congress defection in the 1977 elections is a case in point. The lesson learnt is that it is difficult to enforce a law unless the majority of people are in favour of it and if it does not interfere with the rights of the individual.

However, laws may be useful in times of emergency or in limited situations such as control of an epidemic disease or management of fairs and festivals. Even in cases where it is the duty of the government to make laws to prevent the spread of disease (e.g., AIDS) it is difficult to enforce laws without a vast administrative infrastructure and considerable expenditure. To a degree, the people must be ready to accept a law. In short, the coercive approach runs counter to the basic tenet of health education, that is, in health education, we do not force people to change. In specific situations, legislation can be used to reinforce the pressure to change collective behaviour.
2. Service approach

This approach was tried by the Basic Health Services in 1960s. It aimed at providing all the health services needed by the people at their door steps on the assumption that people would use them to improve their own health. This approach proved a failure because it was not based on the felt needs of the people. The people who lived in the latrines were provided by the government, free of cost, many people in the rural areas did not make use of them because it was not their habit to use latrines. The lesson is simple – the people will not accept a programme or service, even if it is offered free of cost, unless it is based on their felt needs.

3. Health education approach

There are many problems (e.g., cessation of smoking, use of safe water supply, fertility control) which can be solved only through health education. It is a general belief in western democracies that people will be better off if they have autonomy over their own lives, including health affairs on which an informed person should be able to make decisions to protect his own health. These are the higher goals of health education. However, if the necessary behaviour changes are to take place, people must be educated through planned learning experiences what to do, and be informed, educated and encouraged to make their own choice for a healthy life. This approach is consistent with democratic philosophy which does not “order” the individual. The results are slow, but enduring. The mass media and social organizations must be mobilized to help introduce new attitudes and new habits without conflicting with the masses and the collective reaction to particular change.

Since attitudes and behaviour patterns are formed early in life, it is very difficult to change them later. One must act early in order to start healthy education with young population. The assumption is that behaviour is more easily controlled or developed in young population than adults (16).

4. Primary health care approach

This is a radically new approach starting from the people with their full participation and active involvement in the planning and delivery of health services based on principles of primary health care, viz. community involvement and intersectoral coordination. The underlying objective is to help individuals to become self-reliant in matters of health. This, in turn, can be done if the people receive the necessary guidance from health care providers in identifying their health problems and finding workable solutions. This approach is a fundamental shift from the earlier approaches.

Health education versus propaganda

Health education is not health propaganda; it is more than mere information or propaganda. To educate means to cause or facilitate learning; propaganda means to spread particular systematized doctrine. The differences between health education and propaganda drawn up by the Central Health Education Bureau, Government of India are given in Table 1.

MODELS OF HEALTH EDUCATION

During the past few decades, a number of health education models have been developed (6). They include the following:

1. Medical model

Most health education in the past has relied on knowledge transfer to achieve behavioural changes. The medical model is primarily interested in the recognition and treatment of disease (curing) and technological advances to facilitate the process. It is concerned with disease (as defined by the doctor) or opposed to illness (as defined by the client).

Originally health education developed along the lines of the bio-medical views of health and disease. The emphasis was on dissemination of health information based on scientific facts. The assumption was that people would act on the information supplied by health professionals to improve their health. In this model, social, cultural and psychological factors were thought to be of little or no importance. The medical model did not bridge the gap between knowledge and behaviour.

2. Motivation model

When people did not act upon the information they received, health education started emphasizing “motivation” as the main force to translate health information into the desired health action. But the adoption of a new behaviour or idea is not a simple act, it is a process consisting of several stages through which an individual is likely to pass.

<table>
<thead>
<tr>
<th>TABLE 1</th>
<th>Health education and propaganda</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Knowledge and skills actively acquired</td>
<td>Knowledge instilled in the minds of people</td>
</tr>
<tr>
<td>2. Makes people think for themselves</td>
<td>Prevents or discourages thinking by ready-made slogans</td>
</tr>
<tr>
<td>3. Disciplines primitive desires</td>
<td>Arouses and stimulates primitive desires</td>
</tr>
<tr>
<td>4. Develops reflective behaviours. Trains people to use judgement before acting</td>
<td>Develops reflective behaviour; aims at impulsive actions</td>
</tr>
<tr>
<td>5. Appeals to reason</td>
<td>Appeals to emotion</td>
</tr>
<tr>
<td>6. Develops individuality, personality and self-expression</td>
<td>Develops a standard pattern of attitudes and behaviours according to the mould used</td>
</tr>
<tr>
<td>7. Knowledge acquired through self-reliant activity</td>
<td>Knowledge is spoon-fed and passively received</td>
</tr>
<tr>
<td>8. The process is behaviour centred – aims at developing favourable attitudes, habits and skills</td>
<td>The process is information centred – no change of attitude or behaviour designed.</td>
</tr>
</tbody>
</table>
Reliance on only one method is likely to lead to failures. A combination of approaches using all methods to change lifestyle and appropriate use of medical care will be necessary.

**CONTENTS OF HEALTH EDUCATION**

The scope of health education extends beyond the conventional health sector. It covers every aspect of family and community health. While no definitive training curricula can be proposed, the content of health education may be divided into the following divisions for the sake of simplicity. Since health education has a limited impact when directed from general education, most of the needed information must be integrated into the education system (by way of books, class-room material, etc.) and must have the young population as the principal target.

1. **Human biology**
   - Understanding health, demands an understanding of the human biology, i.e., the structure and functions of the body
   - How to keep physically fit - the need for exercise, rest and sleep; the effects of alcohol, smoking and drugs on the body
   - Cultivation of healthy lifestyles, etc.
   - Reproductive biology is another area of current interest
   - UNICEF's "State of the World's Children report 1989" has drawn up a basic list of health information which it believes, every family has a right to know. The list comprises of child teaching, breast-feeding, safe motherhood, immunization, weaning and child growth, diarrhoeal disease, respiratory infections, house hygiene - which could enable families to bring about significant improvements in their own and their children's health.

   The best place to teach human biology is the school. It is only the school, through its sequential health curriculum, which can provide continuous in-depth learning experiences for millions of students. The provision of information and advice on human biology and hygiene is vital for each new generation.

2. **Nutrition**
   - The aim of nutrition education is to guide people to choose optimum and balanced diets, remove prejudices and present food as a way of life.

3. **Sanitation**
   - Hygiene
   - This has two aspects - personal and environmental. The aim of personal hygiene is to promote standards of personal cleanliness within the setting of the condition where people live.

comprises that of the home, use of soap, need for fresh air, light and ventilation; hygienic storage of foods; hygienic disposal of wastes, need to avoid pests, rats, mice and insects. Improvement of environmental health is a major concern of many governments and related agencies throughout the world. In the developing countries, the emphasis is on the improvement of basic sanitary services consisting of water supply, disposal of human excreta, other solid and liquid wastes, vector control, food sanitation and housing which are fundamental to health. In many areas, poor sanitary practices among the people have their roots in centuries - old customs, styles of living and habits. These are not easily altered (17).

An environmental sanitation programme should include health education. It is not enough to provide sanitary wells, latrines and waste collecting facilities. People will continue to suffer from the diseases caused by poor sanitation if they do not use the facilities. If a health education approach is taken, people will participate from the beginning in identifying their sanitation problems and will choose the solutions and facilities they want. They will then be more likely to use these facilities and improve their health.

4. Family health

The family is the first defence, as well as the chief reliance for the well-being of its members. Health largely depends on the family's social and physical environment and its lifestyle and behaviour. The role of the family in health promotion and in prevention of diseases, early diagnosis and care of the sick is of crucial importance. One of the main tasks of health education is to promote the family's self-reliance, especially regarding the family's responsibilities in childbearing, child rearing, self-care and in influencing their children adopt a healthy lifestyle.

5. Disease prevention and control

Drugs alone will not solve health problems without health education, a person may fall sick again and again from the same disease. The experiences of western countries have shown the role of education in the eradication of cholera, typhoid, malaria and tuberculosis etc. Education of the people about the prevention and control of locally endemic diseases is the first of eight essential activities in primary health care. Several public health programmes are in operation on a national scale to eradicate diseases such as malaria, tuberculosis, leprosy, filaria, goitre, etc. The recent experience of malaria eradication has indicated that anti-malarial spray with insecticides cannot solve the problem without health education.

6. Mental health

Mental health problems occur everywhere. They become more prominent when major killer diseases are brought under control. There is a tendency to an increase in the prevalence of mental diseases when there is a change in the society from an agricultural to an industrial economy, and when people move from the warm intimacy of a village community to the isolation found in big cities. The aim of education in mental health is to help people to keep mentally healthy and to prevent a mental breakdown. People should enjoy their relationships with others and learn to live and work without mental breakdown. There are certain special situations when mental health is of great importance - mother after child birth; child at entry into school for the first time, school child entering the secondary school; decision about a future career, starting a new family and at the time of widowhood. These are critical periods of life when external pressure tends to breakdown mental health. Health workers should help people achieve mental health by showing sympathy, understanding and by social contact.

7. Prevention of accidents

Accidents are a feature of the complexity of modern life. In the developed countries, they are taking an increasing toll of life and limb. Accidents occur in three main areas - the home, road and the place of work. Safety education should be directed to these areas. It should be the concern of the engineer the designer and the educator of the police department to enforce rules of road safety. Accidents occur in workshops, factories, railways and mines. Medical staff must provide a safe environment and promote general order and cleanliness. There should be a place for everything, and everything should be in its place in the factory, in the home, and in the office. The predominant factor in accidents is carelessness and the problem can be tackled through health education.

8. Use of health services

Many people particularly in rural areas do not know what health services are available in their community, and many more do not know what signs to look for that indicate a visit to the doctor is necessary. Studies indicate that the public attitude towards health services is still apprehensive. There is a communication gap between the public and the state health administration in the form of "feedback" for further improvement of health services.

One of the declared aims of health education is to inform the people about the health services that are available in the community and how they can utilize them (e.g., screening programmes, immunization, family planning services etc.) and use the health care resources.

PRINCIPLES OF HEALTH EDUCATION

Before we come to the practice of health education, we must know the principles involved. Health education brings together the art and science of medicine, and the principles and practice of general education. The link is to be found in the social and behavioural sciences - sociology, psychology and social anthropology.

Health education cannot be "given" to one person by another. It involves, among other things, the teaching, learning and inculcation of habits concerned with the objective of healthful living. Psychologists have given a great deal of attention to the learning process. Every individual learns and through learning develops the modes of behaviour by which he lives. Learning and teaching is a two-way process of transactions in human relations, between the teacher and taught. The teacher cannot teach unless the pupil wants to learn. Learning takes place not only in the class room, but also outside in the wider world. There is informal learning by which a man grows into an adult individual. It is possible to abstract certain principles of learning and use them in health education. These include:

1) Credibility: It is the degree to which the message to be communicated is perceived as trustworthy by the receiver. Good health education is based on facts - that means it must be consistent and compatible with scientific knowledge and also with the local culture, educational system and social goals. Unless the people have trust and confidence in the communicator, no desired action will ensue after receiving the message.
(2) Interest: It is a psychological principle that people are unlikely to listen to those things which are not to their interest. It is salutary to remind ourselves that health teaching should relate to the interests of the people. The public is not interested in health slogans such as “Take care of your health” or “be healthy” in a health education programme of this kind would be useless as adding people to “be healthy”, as a nutrition programme asking people to “eat go-astounding” (e.g., on the next exercise) can be discovering the health needs of the people. Psychologists call them “felt needs”, that is, needs the people feel about themselves. If a health programme is to be successful, it must find and really participate in; the programme; and only then will it be a people’s programme. Very often, there are groups who may have health, that of which they are not aware. This is especially true in India where about 25% per cent of the people are illiterate. The health educator will have to bring about a recognition of the needs; before he proceeds to tackle them.

(3) Participation: Participation is a key word in health education. It is based on the psychological principle of active learning. Health education should aim at encouraging people to work actively with health workers and others in identifying their own health problems and also in developing solutions and plans to work them out. Participation of family members in patient care will create opportunity for more effective, practically based health education. A high degree of participation tends to create a sense of involvement, personal acceptance and decision-making. It provides maximum feedback. The Alma-Ata Declaration states: “The people have a right and duty to participate individually and collectively in the planning and implementation of their health care” (18). If community participation is not an integral part, health programmes are unlikely to succeed (19).

(4) Motivation: In every person, there is a fundamental desire to learn. Awakening this desire is called motivation. There are two types of motives – primary and secondary. Primary motives (e.g., sex, hunger, survival) are driven forces initiating people into action; these motives are inborn desires. Secondary motives are based on desires created by outside forces or incentives. Some of the more everyday motives are praise, love, rivalry, rewards and punishment, and recognition. In health education, motivation is an important factor. Motivation offers the key to learning to change. The incentives may be positive (the carrot) or negative (the stick). To tell a lady, faced with the problem of overweight, to reduce her weight may add a little more attractive, and beautiful, she might accept health advice. When a father promises his child a reward for getting up early, he is motivating the child to incultate a good habit. In health education, we make use of motivation to change behaviour. Motivation is contagious; one motivated person may spread motivation throughout. For example, men who have already had vasectomies are among the best advertisements for male sterilization.

(5) Comprehension: In health education we must know the level of understanding, education and literacy of people to whom the teaching is directed. One barrier to communication is using words which cannot be understood. A doctor asked the diabetic to cut down starch foods; the patient had no idea of starch foods. A doctor prescribed medicine in the familiar jargon “two teaspoonful three times a day”;
the patient, a village woman, had never seen a teaspoon, and could not follow the doctor’s directions. In health education, we should always communicate in the language people understand, and never use words which are strange and new to the people. Teaching should be within the mental capacity of the audience.

(6) Reinforcement: Few people can learn all that is new in a single period. Repetition at intervals is necessary. If there is no reinforcement, there is very little possibility of the individual going back to the pre-awareness stage. If the message is repeated in different ways, people are more likely to remember it.

(7) Learning by doing: Learning is an action process; not a “memorizing” one in the narrow sense. The Chinese proverb: “If I hear, I forget; if I see, I remember; if I do, I know” illustrates the importance of learning by doing.

(8) Known to unknown: In health education work, we must proceed "from the concrete to the abstract"; “from the particular to the general”; “from the easy to the more difficult”; and “from the known to the unknown”. These are the rules in teaching. We start where the people are and with what they understand and then proceed to new knowledge. We use the existing knowledge of the people as pegs on which to hang new knowledge. In this way systematic knowledge is built up. New knowledge will bring about a new, enlarged understanding which can give rise to an insight into the problem. The way in which medicine has developed from religion to modern medicine serves us as an illustration, the growth of knowledge from the unknown to the known. It is a process of grasping the full of obstacles and resistance, and we must not expect quick results.

(9) Sitting on example: The health educator should set a good example in the things he is teaching. If he is explaining the hazards of smoking, he will not be very successful if he himself smokes. If he is talking about the “small family norm”, he will not get very far if his own family size is big.

(10) Good human relations: Sharing of information, ideas and feelings happen most easily between people who have a good relationship. Building good relationship with people goes hand in hand with developing communication skills.

(11) Feedback: Feedback is one of the key concepts of the systems approach. The health educator can modify the elements of the system (e.g., message, channels) in the light of feedback from his audience. For effective communication, feedback is of paramount importance.

(12) Leaders: Psychologists have shown and established that we learn best from people whom we respect and regard. In the work of health education, we try to penetrate the community through the local leaders – the village headman, the school teacher or the political workers. Leaders are agents of change and they can be made use of in health education work. If the leaders are convinced first about a given programme, the rest of the task of implementing the programme will be easy. The attributes of a leader are: he understands the needs and demands of the community; provides proper guidance, takes the initiative, is receptive to the views and suggestions of the people; identifies himself with the community; selfless, impartial, considerate and sincere; easily accessible to the people; able to control and compromise the various factions in the community; possesses the requisite skill and knowledge of eliciting cooperation and achieving coordination of the various official and non-official organisations.
PRACTICE OF HEALTH EDUCATION

Educational material should be designed to focus attention to provide new knowledge, to facilitate interpersonal and group discussion and to reinforce or clarify prior knowledge and behaviour.

1. Audio-visual aids

No health education can be effective without audiovisual aids. They help to simplify unfamiliar concepts; bring about understanding where words fail; reinforce learning by appealing to more than one sense, and provide a dynamic way of avoiding monotony. Modern science has made available an endless array of audiovisual aids which can be classified into three groups (20):

(1) AUDITORY AIDS
Radio, tape-recorder, microphones, amplifiers, earphones.

(2) VISUAL AIDS
(a) Not requiring projection: Chalk-board, leaflets, posters, charts, flannelgraphs, exhibits, models, specimens, etc.
(b) Requiring projection: Slides, film strips.

(3) COMBINED A-V AIDS
Television, sound film, (Cinema), slide-tape combination.

A knowledge of the advantages, disadvantages and limitations of each audio-visual aid is necessary in order to make proper use of them. Audio-visual aids are means to an end, not an end in themselves.

2. Methods in health communication

The methods in health communication may be grouped as in Fig. 3.

A rundown of the assets of mass media and personal communication methods is shown in Table 2.

Any one or a combination of these methods can be used selectively at different times, depending upon the objectives to be achieved, the behaviour to be influenced and available funds.

1. Individual approach

There are plenty of opportunities for individual health education. It may be given in personal interviews in the consultation room of the doctor or in the health centre or in the homes of the people. The individual comes to the doctor or health centre because of illness. Opportunity is taken in educating him on matters of interest—diet, causation and nature of illness and its prevention, personal hygiene, environmental hygiene, etc. Topics for health counselling may be selected according to the relevance of the situation. By such individual health teaching, we will be equipping the individual and the family to deal more effectively with the health problems. The responsibility of the attending physician in this regard, is very great because he has the confidence of the patient. The patient will listen more readily to the physician's health counselling. A hint from the doctor may have a more lasting effect than volumes of printed word. The nursing staff also have ample opportunities for undertaking health education. Florence Nightingale said that the nurse can do more good in the home than in the hospital. Public health nurses, health visitors and health inspectors are visiting hundreds of homes; they have plenty of opportunities for individual health teaching. In working with individuals, the health educator must first create an atmosphere of friendship and allow the individual to talk as much as possible. The biggest advantage of individual health teaching is that we can discuss, argue and persuade the individual to change his behaviour. It provides opportunities to ask questions in terms of specific interests. The limitation of individual health teaching is that the numbers we reach are small, and health education is given only to those who come in contact with us.

2. Group approach

Our society contains groups of many kinds—school children, mothers, industrial workers, patients, etc. Group teaching is an effective way of educating the community. The choice of subject in group health teaching is very important; it must relate directly to the interest of the group. For example, we should not teach the subject of tuberculosis control to a mother who has come for delivery; we should talk to her about child-birth and baby care.

Similarly, school children may be taught about oral hygiene, tuberculosis patients, or about tuberculosis; and industrial workers about accidents. We have to select also the suitable method of health education including audio-visual aids for successful group health education. A brief account of the methods of group teaching is given below:

1. Chalk and talk (Lecture)
   A lecture may be defined as carefully prepared oral presentation of facts, organized thoughts and ideas by a qualified person. The "chalk" lends the visual component. The chalk and talk, communication has still a very important place in small group education. Its effectiveness depends on a large extent on the speaker’s ability to write legibly and to draw with chalk on a black board. The talk should be based on a topic of current interest or health needs of the group. The group should not be more than 30 and the talk should not exceed 15 to 20 minutes. If the talk is too long people may become bored and restless.

The lecture method can be made more effective by combining with suitable audio-visual aids such as:

- **Flipcharts**: They consist of a series of charts (or posters), about 25 by 30 cm or more, each with an illustration pertaining to the talk to be given. They are meant to be shown one after another. Each chart is "flushed" or displayed before a group as the talk is being given. The message on the charts must be brief and to the point. These charts are primarily designed to hold attention of the group and help the lecturer to proceed.

- **Flannelgraphs**: A piece of rough flannel or khadi fixed over a wooden board provides an excellent background for displaying cut-out pictures, graphs, drawings and other illustrations. The cut-out pictures and other illustrations are provided with a rough surface at the back by pasting pieces of sand paper, felt or rough cloth and they adhere at once when put on the flannel. Flannelgraphs offer the advantage that pre-arranged sequence of pictures displayed one after another helps maintain continuity and adds much to the presentation. The other advantages are that the flannelgraph is a very cheap, medium, easy to transport and presents thought and criticism.

- **Exhibits**: Objects; models, specimens, etc. convey a specific message. These may be a story of mass media of communication, which can also be used in group teaching.

- **Films and charts**: These are mass media of communication. If used with discrimination, they can be of value in educating small groups.

Lectures can be faulted on a number of grounds. Their disadvantages include the following: students are involved to a minimum extent; learning is passive; do not stimulate thinking or problem-solving capacity; the comprehension of a lecture varies with the student; and the health behaviour of the listeners is not necessarily affected.

2. Demonstrations
A demonstration is a carefully prepared presentation to show how to perform a skill or procedure. Here a procedure (e.g., bandage placement, dissection of a well) is carried out step by step before an audience or the target group, the demonstrator ascertaining that the audience understands how to perform it. The demonstrator involves the audience in discussion.

Demonstration (a) dramatizes by arousing interest (b) persuades the lookers on to adopt recommended practices (c) upholds the principles of "seeing is believing" and "learning by doing", and (d) can bring desirable changes in the behaviour pertaining to the use of new practice.

Demonstration as a means of communication has been found to have a high educational value in programmes like environmental sanitation (e.g., installation of a hand-pump, construction of a sanitary latrine); mother and child health (e.g., demonstration of oral rehydration technique) and control of diseases (e.g., scabies). The clinical teaching in hospital is based on demonstrations. This method has a high motivational value.

3. Group discussion
A "group" is an "aggregation of people interacting in a face-to-face situation." This contrasts sharply to the group of students in a class room situation. Group discussion is considered a very effective method of health communication. It permits the individuals to learn by freely exchanging their knowledge, ideas and opinions. Group discussion provides a wider interaction among members than is possible with other methods. Where long term compliance is involved (e.g., cessation of smoking, obesity reduction) group discussion is considered very valuable.

For effective group discussion, the group should comprise not less than 6 and not more than 12 members. The participants are all seated in a circle, so that each is fully visible to all the others (Fig. 4). There should be a group leader who initiates the subject, helps the discussion in the proper manner, prevents side-conversations, encourages everyone to participate and sums up the discussion in the end. If the discussion goes well, the group may arrive at decisions which no individual member would have been able to make alone. It is also desirable to have a person to
word whatever is discussed. The "recorder" prepares a report on the issues discussed and agreements reached. In a group discussion, the members should observe the following rules: (a) express ideas clearly and concise, (b) listen to what others say, (c) do not interrupt what others are speaking, (d) make only relevant remarks, (e) accept criticism gracefully, and (f) help to reach conclusions. Group discussion is successful if the members know each other beforehand, when they can discuss freely.

A well-conducted group discussion with adequate resources (Fig. 4) is very effective in reaching decisions, based on the ideas of all people. The decision taken by the group tends to be adopted more readily than in situations where the decision is a solitary one. Thus, the group acceptance has a binding effect on the individual member to translate their acceptance into action. A well-conducted group discussion is effective for changing attitudes and the health behaviour of people.

(4) Panel discussion

In a panel discussion, 4 to 8 persons who are qualified to talk about the topic sit and discuss a given problem, or the topic, in front of a large group or audience. The panel comprises a chairman or moderator and from 4 to 8 speakers. The chairman opens the meeting, welcomes the group and introduces the panel speakers. He introduces the topic briefly and invites the panel speakers to present their points of view. There is no specific agenda, no order of speaking and no set speeches (21). The success of the panel depends upon the chairman; he has to keep the discussion going and develop the main thread. After the main aspects of the subject are explored by the panel speakers, the audience is invited to take part. This discussion should be spontaneous and natural. If members of the panel are unacquainted with this method, they may have a preliminary meeting, prepare the material on the subject, and decide upon the method and plan of presentation. Panel discussion can be an extremely effective method of education, provided it is properly planned and guided.

(5) Symposium (22, 23)

A symposium is a series of speeches on a selected subject. Each person or expert presents an aspect of the subject briefly. There is no discussion among the symposium members like in panel discussion. In the end, the audience may raise questions. The chairman makes a comprehensive summary at the end of the entire session.

(6) Workshop (21, 22, 23)

The workshop is the same given to a novel experiment in education. It consists of a series of meetings, usually four or more, with emphasis on individual work, within the group, with the help of consultants and professional personnel. The total workshop may be divided into small groups and each group will choose a chairman and a recorder. The individual's work, solve a part of the problem through their personal effort, with the help of consultants, contribute to group work and group discussion and leave the workshop with a plan of action on the problem. Learning takes place in a friendly, happy and democratic atmosphere, under expert guidance. The workshop provides each participant opportunities to improve his effectiveness as a professional worker.

(7) Role playing (21, 22)

Role playing or sko-drama is based on the assumption that many values in a situation cannot be expressed in words, and the communication can be more effective if the situation is dramatised by the group. The group members who take part in the sko-drama enact their roles as they have observed or experienced them. The audience is not passive but actively concerned with the drama. They are supposed to pay sympathetic attention to what is going on, suggest alternative solutions at the request of the leader, and if requested, come up and take an active part by demonstrating how they feel a particular role should be handled, or the like. The size of the group is thought to be best at about 25. Role playing is a useful technique to use in providing discussion, of problems of human relationship. It is a particularly useful communication device for school children. Role playing is followed by a discussion of the problem.

(8) Conferences and seminars

This category contains a large component of commercialized continuing education. The programs are usually held on a regional, state, or national level. They range from once or twice a year to one week in length and may cover a single topic in depth or be broadly comprehensive. They usually use a variety of forums to aid the learning process from self-instruction to multimedia.
3. Mass approach – Education of the general public

No health worker or health team can mount an effective health education programme for the whole community, except through mass media of communication. The evolution of the media has been rapid. Until the early 1950s, mass communication depended largely on what was printed – posters, pamphlets, books, periodicals and newspapers. Then came the radio and with it a new dimension of experience. TV went a gigantic step further and has become a very powerful weapon. The press, naturally, primarily to the eye, the radio appeals to the ear, and TV to both eye and ear. A final word about radio and TV – they are close to the warm and motivational effect of a peer-to-peer-person communication. They have become part of the fabric of modern civilization.

Mass media are a “one-way” communication. They are useful in transmitting messages to people even in the remotest places. The number of people who are reached usually count in millions. Their effectiveness can give high returns for the time and money involved.

Mass media alone are generally inadequate in changing human behavior. For effective health communication, they should be used in combination with other methods. The power of mass media in creating a political will in favour of health, raising the health consciousness of the people, setting norms, delivering technical messages, popularizing health knowledge and fostering community involvement are well recognized (6). Public health methodologies should be culturally appropriate; they should be carefully thought-out before use. A brief account of the mass media is given below:

1. Television

Television has become the most popular of all media. It is effective in not only creating awareness, but also to an extent influencing public opinion and introducing new ways of life. It is raising levels of understanding and helping people familiarise with things they have not seen before, including crime and violence which are shown as part of feature programmes. TV is a one-way channel. It can only be an aid to teaching. It cannot cover all areas of learning. It has much potential for health communication.

2. Radio

Radio is found nearly in every home. In many developing countries the radio has a broader audience than TV. Both radio and TV can reach illiterate population not accessible through printed word. It is a purely didactic medium. It can be valuable aid in “putting across” useful health information, in the form of straight talks, plays, question and answers and quiz programmes. Radio is much cheaper than TV. Doctors and health workers may speak out on radio. Local health issues may be identified and discussed leading to increases general awareness.

3. Internet

This new means of computer based communication system has opened vast capability of transfer of knowledge, and has made it possible to get into direct and instant communication across the world by means of e-mail and even a on-line chat. This is a fast growing communication media and holds very large potential to become a major health education tool. Already a fairly large number of persons in India are using this media, and the numbers are growing everyday. Vast amount of health related literature from WHO and other health agencies is available on line. The Health related information from the ministry of health and family welfare Govt. of India, is also available on their website.

4. Newspapers

Newspapers are the most widely disseminated of all forms of literature. News must be newsworthy before it is printed. Whereas many people turn to radio or TV for entertainment, newspaper readers are often serious. Newspapers. Newspapers should, therefore, provide more factual, detailed and even statistical material (7). Unfortunately, health problems have little value to newspaper. Newspapers have limitation of having low readership in rural areas because of illiteracy. They reach only a limited group, i.e. the literates in the community.

5. Printed material

Magazines, pamphlets, booklets and hand-outs have long been in use for health communication. They are aimed at those who can read. Their usefulness lies in the fact that they can convey detailed information. They can be produced in bulk for very little cost, and can be shared by others in the family and community.

6. Direct mailing

This is a new innovation in health communication in India. The intention is to reach the remote areas of the country with printed word (e.g., folders and newsletters and booklets on family planning, immunization and nutrition etc.). They are sent directly to village leaders, literate persons, panchayats and local bodies and others who are considered as opinion leaders. Direct mailing has been a successful mass media in creating public awareness. It is possibly the most personal of mass communication.

7. Posters, billboards and signs

These are intended to catch the eye and create awareness. Therefore, the message to be communicated must be simple, and artistic. Posters are not expensive when one considers they are seen by a large number of people. Motives such as humour and fear are introduced into posters in order to hold the attention of the public. In places where the exposure time is short (e.g., streets), the message of the poster should be short, simple, direct and one that can be taken at a glance and easy to understand immediately. In places where people have some time to spend (e.g., bus stops, railway stations, hospitals, health centres) the poster can present more information. The right amount of matter should be put up in the right place and at the right time. That is, when there is an epidemic of viral hepatitis, there should be posters displayed on viral jaundice, but not on cholera. The life of a poster is usually short; posters should be changed frequently, otherwise they will lose their effect. As a media of health education, posters have much less effect in changing behaviour than its enthusiastic users would hope. Indiscriminate use of posters by pasting them on walls serves no other useful purpose than cowering the wall.

8. Health museums and exhibitions

If properly organized, health museums and exhibitions can attract large numbers of people. By presenting a variety of ideas, they do increase knowledge and awareness. Photographic panels attract more persons than graphic panels. This is because photos give a humanized touch to the communication. The three dimensional models with lighted visuals are even more effective than photos.
In exhibitions, there is a big element of personal communication through workers who explain each item on the exhibit. Printed literature explaining the exhibits is often freely distributed. Health exhibitions and museums thus offer a package of both personal and impersonal methods of communication.

9. Folk media

The term "mass communication" ought to refer to the totality of communication which takes within its compass not only the electronic media, but also folk (or indigenous), media such as keethan, ketha, folk songs, dances and dramas and puppet shows which have roots in our culture. The muscles have their own traditional fus forum like the ghazals, the khasi.

The mass media are only "instruments". As such they are neither good nor bad; what matters is the message they convey and the way the message is delivered (6). There is no single way to do public education. Health education is still art rather than a science. Each community and country should develop techniques that meet its own needs.

PLANNING AND MANAGEMENT

Health education cannot be planned in a vacuum. It is planned in connection with a specific health programme or health service. Therefore, the specifics of a health education strategy in a local community have to be formulated in accordance with its socio-cultural, psycho-social, political, economic and situational characteristics. The planners should be fully conversant with the health education needs of the particular programme for which health education is to be planned.

Health education planning follows the main steps in scientific planning, which are:

1. Collecting information on specific problems as seen by the community
2. Identification of the problem
3. Deciding on priorities
4. Setting goals and measurable objectives
5. Assessment of resources
6. Consideration of possible solutions
7. Preparation of a plan of action:
   (i) What will be done?
   (ii) When?
   (iii) By whom?
8. Implementing the plan
9. Monitoring and evaluating the degree to which stated objectives have been achieved
10. Reassessment of the process of planning. Planning and evaluation are essential for effective health education. The subject of planning is discussed more fully in chapter 20.

All health education work requires continuous evaluation to measure the effectiveness of health education activities in achieving stated objectives and to assess the importance on programme performance of such variables as knowledge, attitudes, behaviour change and consumer satisfaction.

ADMINISTRATION AND ORGANIZATION

Governments have a responsibility for assisting and guiding the health education of the general public. At the national level, the Government of India in 1956 established a Central Health Education Bureau in the Ministry of Health, New Delhi to promote and coordinate health education work in the country. Some state governments in India have now Health Education Bureaux in their Health Directorates.

There are also other official agencies in the country such as the Directorates of Advertising and Visual Publicity (DAVP), Press Information Bureau, Doordarshan and All India Radio which are active in health education work. Several voluntary bodies such as Indian Red Cross are also engaged in the health education work. At the international level, there is an International Union for Health Education with headquarters in Paris, whose main task is to promote the creation of national societies for health education. The South East Asia Regional Bureau (SEARB) of the International Union for Health Education was established in 1983 with headquarters at Bangalore.

A new division of Health Education and Health Promotion has been established by the WHO. The division will support regional offices of WHO in strengthening national capabilities in health education and promotion and develop and test new ideas and tools. (The former Division of Public Information and Education for Health was now called Division of Public Information and Public Relations).

Health education is a complex activity in which different individuals and organizations play a part. Among them are parents, teachers, friends, physicians, nurses, health workers and various organizations, governmental and non-governmental. No country in the world, least of all a country with a large population and small resources such as India, can afford to employ institutionally trained health workers alone. Therefore, health education should concern everybody engaged in any form of community welfare work.

References
18. Health For All, No. 1.
20. WHO (1972). Public Health Papers No.47, p. 5:.
Planning and management are relatively new subjects. Planning is for tomorrow, and management is for today. These subjects have acquired great importance during the past two decades. The purpose of planning is (1) to match the limited resources with many problems; (2) to eliminate wasteful expenditure or duplication of expenditure; and (3) to develop the best course of action to accomplish a defined objective. The increasing demand for medical and health care services, in the face of limited resources, has brought out the need for careful planning and management of health services. Planning and management are considered essential if higher standards of health and health care are to be achieved (1).

Planning in its broadest sense includes three steps:
(a) Plan formulation
(b) Execution; and
(c) Evaluation

Planning is a matter of team work and consultation. The planning team consists of not only specialists within the field, but also specialized in other fields, viz. economics, statistics, sociology, management, etc.

DEVELOPMENT PLANNING

Every country has its own plan for national development. The purpose of national planning is to achieve a rapid, balanced, economic and social development of the country as a whole. The National Development Plan of a country is a combination of sectoral plans which comprise the following sectors, viz. food and agriculture, education, health and family planning, industry, transport and communications, housing, power, social welfare, etc. All these sectors compete for national resources (2).

In this context, National Development Planning has been defined as "continuous, systematic, coordinated, planning for the investment of the resources of a country (man, money and materials) in programmes aimed at achieving the most rapid economic and social development possible (3).

HEALTH PLANNING

Health planning is a concept of recent origin. It is part of national development planning. Health planning is necessary for the economic utilisation of material, manpower and financial resources. The purpose of health planning is to improve the health services.

In this context, National Health Planning has been defined as "the orderly process of defining community health problems, identifying unmet needs and surveying the resources to meet them, establishing priority goals that are realistic and feasible and projecting administrative action to accomplish the purpose of the proposed programme" (3).

Health needs and demands

The purpose of health planning is to meet the health needs and demands of the people. Health needs have been defined as "deficiencies in health that call for preventive, curative, control or indication measures" (3); The need for medical care, safe water supply, adequate nutrition, immunization, family planning are all community health needs. It may be mentioned that the health needs as seen by the people are not exactly the same as seen by experts. Some needs may not be perceived at all; others vaguely perceived, and still others awaken only on contact with new ways of life. People's needs are conditioned by their aspirations. In a democratic society, people's needs may be presented as demands.

Resources

The term "resources" is widely used in health planning. It implies the manpower, money, materials, skills, knowledge, techniques and time needed or available for the performance or support of action directed towards specified objectives. The resources can be readily wasted if there is no proper planning and management.

Objectives, targets and goals

A number of words are used to describe the end-results of planning — objective, target, goal. These words are drawn from military and sports terminology. An important element of planning is the setting of clear-cut objectives, targets and goals. Let us consider the meaning of these words:

An OBJECTIVE (point) is precise — it is either achieved or not achieved. It is a planned end-point of all activities. A TARGET often refers to a discrete activity such as the number of blood films collected or vaccinations done; it permits the concept of degree of achievement. Targets are thus concerned with the factors involved in a problem, whereas objectives are concerned directly with the problem itself.

GOAL is defined as the ultimate desired state towards which objectives and resources are directed. Unlike objectives and targets, goals are not constrained by time or existing resources, nor are they necessarily attainable. Goals formulated at the highest level are generally broad. A goal is usually described in terms of (1) what is to be attained; (2) the extent to which it is to be attained; (3) the population or section of the environment involved; (4) the geographic area in which the proposed programme will operate; and (5) the length of time required for attaining the goal (3).
Plan
Planning results in the formulation of a Plan. A "Plan" is a blue print for taking action. It consists of five major elements: objectives, policies, programmes, schedules and budget.

A "programme" is a sequence of activities designed to implement policies and accomplish objectives. A programme gives a step-by-step approach to guide the action necessary to reach a predetermined goal. Programmes must be closely integrated with objectives.

A "schedule" is a time sequence for the work to be done. "Procedures" are a set of rules for carrying out work which, when observed by all, help to ensure the maximum use of available resources and efforts. "Policies" are the guiding principles stated as an expectation, not as a commandment.

Pre-planning
Pre-planning is preparation for planning. The important preconditions are: (a) Government interest: Any plan for the health and welfare of a country must be based on a strong 'political will' as manifested by clear directives or policies given by the political authority. (b) Legislation: The social and health policies formulated may have to be translated into legislation. As an example may be cited the enactment of the Medical Termination of Pregnancy Act, 1971, by the Indian Parliament to protect the health of mothers. (c) Organisation for planning: There should be an organizational structure for the preparation of the various parts of the plan. The Planning Commission in India serves this function. It is composed of full-time planners who are advised by representatives and technical experts in the field of social and economic development as well as political leaders. (d) Administrative capacity: One of the essential pre-conditions of planning is administrative capacity for proper coordination of activities and implementation of the plan at all levels. For the health plan, administrative capacity is vested in the Central and State Ministries of Health.

PLANNING CYCLE
Planning is the broad foundation on which much of the management is based. Planning may be defined as a process of analysing a system, or defining a problem, assessing the extent to which the problem exists as a need, formulating goals and objectives to alleviate or ameliorate those identified needs, examining and choosing from among alternative intervention strategies, initiating the necessary action for its implementation and monitoring the system to ensure proper implementation of the plan and evaluating the results of intervention in the light of stated objectives. Planning thus involves a succession of steps (3, 4, 5). These are as shown in Fig. 1.

FIG. 1
The planning cycle
1. Analysis of the health situation

The first step in health planning is analysis of the health situation. It involves the collection, assessment and interpretation of data to produce a clear picture of the health situation. The following items of data are the minimum essential requirements for health planning:

(a) The population, its age and sex structure
(b) Statistics of morbidity and mortality
(c) The epidemiology and geographical distribution of different diseases
(d) Medical care facilities such as hospitals, health centres, and other health agencies - both public and private
(e) The technical manpower of various categories
(f) Training facilities available
(g) Attitudes and beliefs of the population towards disease, its cure and prevention.

The analysis and interpretation of the above data brings out the health problems, the health needs and health deficits of the population.

2. Establishment of objectives and goals

Objectives and goals are needed to guide efforts. Unless objectives are established, there is likely to be haphazard activity, un economical use of funds and poor performance. Objectives must be established at all levels, down to the smallest organizational unit. At upper levels, objectives are general; at successively lower levels, they become more specific and detailed. The objectives may be short-term or long-term. In setting these objectives, time and resources are important factors. Objectives may be stated in broad terms, but also a yardstick to measure work after it is done. Modern management techniques such as "cost-benefit" analysis, and "input-output" study of health services are being used for defining goals, objectives and targets in more definite terms than hitherto.

3. Assessment of resources

The term resources implies the manpower, money, materials, skills, knowledge and techniques needed or available for the implementation of the health programmes. These resources are assessed and a balance is struck between what is required and what is available, or likely to be available in terms of resources.

4. Fixing priorities

Once the problems, resources and objectives have been determined, the next most important step in planning is establishment of priorities in order of importance or magnitude, since the resources always fall short of the total requirement. In fixing priorities, attention is paid to financial constraints, mortality and morbidity data, diseases which can be prevented at low cost, saving the lives of younger people in whom there has been considerable social investment; and also political and community interests and pressures.

Once priorities have been established, ALTERNATIVE PLANS for achieving them are also formulated and assessed in order to determine whether they are practicable and feasible. Alternate plans with greater effectiveness are chosen.

5. Write-up of formulated plan

The next major step in the planning process is the preparation of the detailed plan or plans. The plan must be complete in all respects for the execution of a project. For each proposed health programme, the resources (inputs) required are related to the results (outputs) expected. Each stage of the plan is defined and costed and the time needed to implement is specified. The plan must contain working guidance to all those responsible for execution. It must also contain a "built-in" system of evaluation. It will be left to the central planning authority and the government to consider modifications of the plan relating to allocation of resources.

6. Programming and implementation

Once the health plan has been selected and approved by the policy-making authorities, programming and implementation are begun. Plan execution depends upon the existence of effective organization. The organizational structure must incorporate well-defined procedures to be followed and sufficient delegation of authority to and fixing of responsibility of different workers for achieving the predetermined objectives during the period prescribed. It is at the implementation stage that shortcomings often appear in practice. Many well considered plans have fallen down because of delays in critical supplies, inappropriate use of staff, and similar factors. The main considerations at the implementation stage include: (a) definition of roles and tasks, (b) the selection, training, motivation and supervision of the manpower involved, (c) organization and communication, and (d) the efficiency of individual institutions such as hospitals or health centres.

7. Monitoring

Monitoring is the day-to-day follow-up of activities during their implementation to ensure that they are proceeding as planned and on schedule. It is a continuous process of observing, recording, and reporting on the activities of an organization or project. Monitoring, thus, consists of keeping track of the course of activities and identifying deviations and taking corrective action if excessive deviations occur.

8. Evaluation

The purpose of evaluation is to assess the achievement of the stated objectives of a programme, its adequacy, its efficiency and its acceptance by all parties involved. While monitoring is confined to day-to-day or operational operations, evaluation is mostly concerned with the final outcome and with factors associated with it. Good planning will have a built-in evaluation to measure the performance and effectiveness and for feed-back to correct deficiencies or fill up gaps discovered during implementation. In the words of the National Committee on National Health Planning in Developing Countries, evaluation "measures the degree to which objectives and targets are fulfilled and the quality of the results obtained. It measures the productivity of available resources in achieving clearly defined objectives. It measures how much output or cost-effectiveness is achieved. It makes possible the reallocation of priorities and of resources on the basis of changing health needs" (6).

MANAGEMENT (7)

The term "management" is used in many senses. It is sometimes confused with administration; sometimes with organization. Some equate the terms, management and administration. Others view it as a technique of leadership. The widely prevalent view is that administration broadly means "getting things done" and management as the "purposeful and effective use of resources - manpower,
MANAGEMENT

materials and finances – for fulfilling a pre-determined objective”. In theory, management consists of four basic activities:

(i) planning: determining what is to be done.
(ii) organizing: setting up the framework or apparatus and making it possible for groups to do the work.
(iii) human resource management: motivating people to do the work.
(iv) monitoring (controlling): checking to make sure the work is progressing satisfactorily.

Management techniques are familiar in business, industry, defence and other fields. The current emphasis by WHO and many governments is on improving the efficiency of the health care delivery systems through the application of modern management methods and techniques.

MANAGEMENT METHODS AND TECHNIQUES (1, 8, 9)

Management techniques are many. They are based on principles of behavioural sciences as well as quantitative methods. These techniques have been developed by experts in management science to help the managers of any organization to achieve the stated goals more effectively. Efforts are being made by the WHO for making these techniques more popular for application in the health field. A brief account of these techniques is given below:

Methods based on behavioural sciences

1. ORGANIZATIONAL DESIGN

Poor organization results in waste of resources. It is a theory of management that organization must be suited to its current situation and the needs to be serviced. The organization of health services should, therefore, be designed so as to meet the health needs and demands of the people. Further, the organizational design should be reviewed every few years because of changing concepts or purpose, changing problems and changing technology. Efficient delivery of health services depends upon the existence of an effective organization.

2. PERSONNEL MANAGEMENT

This is a skillful use of human resources. Proper methods of selection, training and motivation; division of responsibility; distribution of roles; elimination of “square pegs in round holes” (i.e., professional staff not suited to administration, either through training, selection or natural inclination, should not be entrusted with administrative and management burdens); incentive for better work; opportunities for promotion and the like; effective design of “health teams” are all fundamental techniques of personnel management which could contribute to the efficiency of health service delivery.

3. COMMUNICATION

Better communication contributes to effective functioning of an organization. Communication roadblocks exist at various levels: between the doctor and the patient; doctor and nurse; between the senior officials and junior; between the directorate and the health ministry; between the health ministry and other ministries and rest of the government. Communication barriers are responsible for delays in regular reporting and notification; delays in the compilation of statistics; delays in the release of supplies and salaries; delays in the institution of prompt remedial measures. In fact, there are some of the major weaknesses in health ministries. One of the tasks of health management is to solve the communication problems by establishing suitable vertical and horizontal communication channels.

4. INFORMATION SYSTEMS

Information is needed for day-to-day management of the health system. Information comes from many sources – both formal and informal. The information system should be tailored according to the management needs of the individual health services. The functions of an information system consist of collection, classification, transmission, storage, retrieval, transformation and display of information. A good information system provides data for monitoring and evaluation of health programmes and gives the requisite feedback to health administrators and planners at all levels. Computers can play a great role in improving the health information system.

5. MANAGEMENT BY OBJECTIVES (MBO)

Objectives are set forth for different units and subunits, each of which prepares its own plan of action – usually on a short-term basis. This helps in achieving the results more effectively and smoothly.

Quantitative methods

Quantitative methods are derived from the field of economics, operation research and budgeting. Some of these techniques have a great role in the management of health services:

1. COST-BENEFIT ANALYSIS

This is a management technique which has attracted the widest attention for application in the health field. The economic benefits of any programme are compared with the cost of that programme. The benefits are expressed in monetary terms to determine whether a given programme is economically sound, and to select the best out of several alternate programmes. The main drawback with this technique is that the benefits in the health field, as a result of a particular programme, cannot always be expressed in monetary terms. We generally express the benefit in terms of births or deaths prevented, or illness avoided or overcome. Hence the scope of applying this method is rather vague.

2. COST-EFFECTIVE ANALYSIS

This is a more promising tool for application in the health field than cost-benefit analysis. It is similar to cost-benefit analysis except that benefit, instead of being expressed in monetary terms is expressed in terms of results achieved, e.g., number of lives saved or the number of days/leé from disease. However, even cost-effective analysis is not possible in many cases.

3. COST-ACCOUNTING (10)

It provides basic data on cost structure of any programme. Financial records are kept in a manner permitting costs to be associated with the purpose for which they are incurred. Cost-accounting has three important purposes in health services: (a) cost control; (b) planning and allocation of people and financial resources; and (c) pricing of cost reimbursement.

4. INPUT-OUTPUT ANALYSIS

Input-output analysis is an economist technique. In the
health field, "input" refers to all health service activities which consume resources (manpower, money, materials and time); and "output" refers to such useful outcomes as cases treated, lives saved or inoculations performed. An input-output table shows how much of each "input" is needed to produce a unit of each "output". It enables calculations to be made of the effects of changing the inputs.

5. MODEL
The model is a basic concept of management science. It is an aid to understand how the factors in a situation affect one another. It is an abstraction of the reality, not the reality itself. The decision process includes the use of a model.

6. SYSTEMS ANALYSIS
The purpose of systems analysis is to help the decision maker to choose an appropriate course of action by investigating his problem, searching out objectives, finding out alternative solutions, evaluation of the alternatives in terms of cost-effectiveness, re-examination of the objectives if necessary and finding the most cost-effective alternative. Systems analysis is essentially finding the cost-effectiveness of the available alternatives. The system can be a hospital supply system, an information system, a total community health service system, an outpatient clinic or any other system with problems of management. A system may be made of independent subsystems.

7. NETWORK ANALYSIS
A network is a graphic plan of all events and activities to be completed in order to reach an end objective (Fig. 2). It brings greater discipline in planning. The two common types of network technique are (a) PERT and (b) CPM.

(a) PERT (Program and Review Technique) is a management technique which makes possible more detailed planning and more comprehensive supervision. Every housewife who plans a meal so that each part of the menu is completed at the same time is using the basic technique of PERT.

The essence of PERT is to construct an Arrow Diagram (Fig. 2). The diagram represents the logical sequence in which events must take place. It is possible with such a diagram to calculate the time by which each activity must be completed, and to identify those activities that are critical. This simple technique provides a basic discipline by which all concerned in a project can know what is expected of them and to minimise any delays or crises in the implementation of the plan.

PERT is a useful management technique which can be applied to a great variety of projects. It aids in planning, scheduling and monitoring the project; it allows better communication between the various levels of management; it identifies potential problems; it furnishes continuous, technical progress reports; it forms a solid foundation upon which to build an evaluation and checking system.

(b) CRITICAL PATH METHOD (CPM) : The longest path of the network (Fig. 2) is called "critical path". If any activity along the critical path is delayed, the entire project will be delayed (11).

8. PLANNING-PROGRAMMING- BUDGETING SYSTEM (PPBS)
The Planning-Programming-Budgeting System (PPBS) is primarily a system to help decision makers to allocate resources so that the available resources of an organization are used in the most effective way in achieving its objectives. The PPBS does not call for changes in the existing organization. It calls for grouping of activities into programs related to each objective. Another approach is known as the "Zero Budget Approach", i.e., all budgets start at zero and no one gets any budget that he cannot specifically justify on a year-to-year basis.

9. WORK SAMPLING
It is systematic observation and recording of activities of one or more individuals, carried out at predetermined or random intervals. It provides quantitative measurement of the various activities. The major parameters that are obtained are the type of activities performed and the time needed to do specified jobs. Work sampling studies have been done on doctors, nurses, pharmacists and laboratory technicians. Work sampling permits judgments to the appropriateness of current staff, job description and training. It helps in standardising the methods of performing jobs and determining the manpower needs in any organization.

10. DECISION MAKING
Decision making is just like the basic discipline of differential diagnosis in medical practice. It is an edage that decisions should be made at the level where the best decisions can be made: it does not follow that the best decision is always made at the top of an organization. Decisions should not be made with incomplete data. In the health sector, decisions have to be made about development of resources, optimum work load for medical and paramedical workers, strategies for providing health care, etc.
NATIONAL HEALTH POLICY-2002 (12)

The Ministry of Health and Family Welfare, Govt. of India, evolved a National Health Policy in 1983 keeping in view the national commitment to attain the goal of Health for All by the year 2000. Since then there has been significant changes in the demarcant factors relating to the health sector, necessitating revision of the policy, and a new National Health Policy-2002 was evolved.

The main objective of this policy is to achieve an acceptable standard of good health amongst the general population of the country. The approach would be to increase access to decentralized public health system by establishing new infrastructure in the existing institutions. Over-riding importance would be given to ensure a more equitable access to health services across the social and geographical expanse of the country. Primary care is to be prevented and first line curative initiatives at the primary health level. The policy is focused on those diseases which are principally contributing to disease burden such as tuberculosis, malaria, blindness and HIV/AIDS. Emphasis will be laid on rational use of drugs within the allopathic system. To translate the above objectives into reality, the Health Policy has laid down specific goals to be achieved by year 2005, 2007, 2010 and 2015. These are as given in Table 1. Steps are already under way to implement the policy.

HEALTH PLANNING IN INDIA

Health planning in India is an integral part of national socio-economic planning (13). The guide-lines for national health planning were provided by a number of committees dating back to the Bhore committee in 1946. These committees were appointed by the Government of India from time to time to review the existing health situation and recommend measures for further action. A brief review of the recommendations of these committees, which are important landmarks in the history of public health in India, is given below.

The Alma-Ata Declaration on primary health care and the National Health Policy of the Government gave a new direction to health planning in India, making primary health care the central function and main focus of its national health system. The goal of national health planning in India was to attain Health for All by the year 2000.

1. Bhore committee, 1946 (14)

The Government of India in 1943 appointed the Health Survey and Development Committee with Sir Joseph Bhore as Chairman, to survey the then existing position regarding the health of the country, and to make recommendations for the future development. The Committee which had among its members some of the pioneers of public health, met regularly for 2 years and submitted in 1946 its famous report which runs into 4 volumes. The Committee put forward, for the first time, comprehensive proposals for the development of a national programme of health services for the country. The Committee observed: "If the nation's health is to be built, the health programme should be developed on a foundation of preventive health work and that such activities should proceed side by side with those concerned with the treatment of patients." Some of the important recommendations of the Bhore Committee were:

(1) Integration of preventive and curative services at all administrative levels;

(2) The Committee visualised the development of primary health centres in 2 stages: (a) as a short-term measure, it was proposed that each primary health centre in the rural areas should cater to a population of 40,000 with a secondary health centre to serve as a supervisory, co-ordinating and referral institution. For each PHC, two medical officers, 4 public health nurses, one nurse, 4 midwives, 4 trained dais, 2 sanitary inspectors, 2 health assistants, one pharmacist, and 15 other class IV employees were recommended (b) a long-term programme (also called the 3 million plan) of setting up primary health units with a health sub-centre for every 10,000 to 20,000 population and secondary units with 600-bedded hospitals, again nationalised around district hospitals and 2,500 beds hospitals.

(3) Major changes in medical education which includes 3 month's training in preventive and social medicine to prepare 'social physicians'.

Although the Bhore Committee's recommendations did not form part of a comprehensive plan for national socio-economic development, the Committee's Report continues to be a national document, and has provided guidelines for national health planning in India.

2. Muldair committee, 1962 (15)

By the close of the Second Five-Year Plan (1956–61), a fresh look at the health needs and resources was called for to provide guidelines for national health planning in the context of the Fifth Five Years Plan. In 1959, the Government of India appointed another Committee known as "Health Survey and Planning Committee", popularly known as the Muldair Committee (after the name of its Chairman, Dr. A.C. Muldair) to survey the progress made in the field of health since submission of the Bhore Committee's Report and to make recommendations for future development and expansion of health services.

The Muldair Committee focused on the quality of services provided by the primary health centres inadequate, and
advised strengthening of the existing primary health centres before new centres were established. It also advised strengthening of the existing centres so that they may effectively function as referral centres.

The main recommendations of the Muddallar Committee were: (1) consolidation of advances made in the first two five-year plans; (2) strengthening of the district hospital with specialist services to serve as central base of regional services; (3) regional organizations in each state between the headquarters organization and the district in charge of a Regional Deputy or Assistant Directors — each to supervise 2 or 3 district medical and health officers; (4) each primary health centre to serve more than 40,000 population; (5) to improve the quality of health care provided by the primary health centres; (6) integration of medical and health services as recommended by the Bhore Committee; and (7) constitution of an All India Health Service on the pattern of Indian Administrative Service.

3. Chadah committee, 1963 (16)

It was held in 1963, a Committee was appointed by the Government of India, under the Chairmanship of Dr. M. S. Chadah, the then Director General of Health Services to study the arrangements necessary for the maintenance phase of the National Malaria Eradication Programme.

The Committee recommended that the "vigilance" operations in respect of the National Malaria Eradication Programme should be the responsibility of the General Health Services, i.e., primary health centres at the block level. The Committee also recommended that the vigilance operations through which vigilance should be implemented through the basic health workers. One basic health worker per 10,000 population was recommended. These workers were envisaged as "multi-purpose" workers to look after additional duties of collection of vital statistics and family planning, in addition to malaria vigilance. The Family Planning Health Assistants were to supervise 3 or 4 of these basic health workers. At the district level, the health services were to take the responsibility for the maintenance phase.

4. Makerji committee, 1965

Within a couple of years of implementation of the Chadah Committee's recommendations by some states, it was realized that the basic health workers could not function effectively as multipurpose workers. As a result the malaria vigilance operations had suffered and also the work of the family planning programme could not be carried out satisfactorily. This subject came up for discussion at a meeting of the Central Health Council in 1965. A committee known as "Makerji Committee, 1965" under the Chairmanship of Shri Makerji, the then Secretary of Health to the Government of India, was appointed to review the strategy for the family planning programme. The Committee recommended separate staff for the family planning programme. The family planning assistants were to undertake family planning duties only. The basic health workers were to be utilized for purposes other than family planning. The Committee also recommended that the malaria activities from family planning so that the latter would receive undivided attention of its staff. The recommendations were accepted by the Government of India.

5. Nukeri committee, 1966 (17)

As the states were finding it difficult to take over the whole burden of the maintenance phase of malaria and other mass programmes like family planning, analphabets, leprosy, trachoma, etc. due to paucity of funds, the matter came up for discussion at a meeting of the Central Council of Health held in Bangalore in 1966. The Council recommended that these and related questions may be referred to the multi-purpose health workers and the Committee constituted under the Chairmanship of the Union Health Secretary, Shri Makerji. The Committee worked out the details of the BASIC (Buyer-Seller) plan, the proposed upgradation plan, and the new block level, and some consequential strengthening required at higher levels of administration.

The Central Council of Health at its meeting held in Srinagar in 1964, taking note of the importance and urgency of integration of health services, and elimination of private practice by government doctors, appointed a Committee known as the "Committee on Integration of Health Services" under the Chairmanship of Dr. N. Jungalwalla, Director, National Institute of Health Administration and Education, New Delhi to examine the various problems including those of service conditions and submit a report to the Central Government in the light of these considerations. The report was submitted in 1967.

The Committee defined "integrated health services" as: (i) a service with a unified approach for all problems instead of a segmented approach for different problems; and (ii) medical care of the sick and conventional public health programmes functioning under a single administrator and operating in unified manner at all levels of hierarchy with due priority for each programme obtaining at a point of time.

The Committee recommended integration from the highest to the lowest level in the services, organization and personnel. The main thrust of the recommendations were: (a) unified cadre (b)common seniority (c) recognition of extra qualifications (d) equal pay for equal work (e) special pay for specialized work (f) no private practice, and good service conditions. The Committee while giving specific indication for action to be taken was careful neither to spell out steps and programmes to indicate an uniform integrated set-up but left the matter to the States to work out the set-up based on the experience of West Bengal, Punjab and Defence Forces. The Committee stated that "integration should be a process of logical evolution rather than revolution."

The Government of India constituted a Committee in 1972 known as the "Committee on Multi-purpose Workers under Health and Family Planning" under the Chairmanship of Katar Singh, Additional Secretary, Ministry of Health and Family Planning, Government of India. The terms of reference of the Committee were to study and make recommendations on: (a) the structure for integrated services at the peripheral and supervisory levels; (b) the feasibility of having multipurpose, bipurpose workers in the field; (c) the training requirements for such workers; and (d) the utilization of mobile service units set up under family planning programme for integrated medical, public health and family planning services operating in the field.

The Committee submitted its report in September 1973. Its main recommendations were: (a) That the present Auxiliary Nurse Midwives be replaced by the newly designated "Female Health Workers", and the present-day Basic Health Workers, Malaria Surveillance Workers,
Vaccinators, Health Education Assistants (Trachoma) and the Family Planning Health Assistants to be replaced by "Male Health Workers". (b) The Programme for having multipurpose workers to be first introduced in areas where malaria is in maintenance phase and smallpox has been controlled, and later to other areas as malaria passes into maintenance phase or smallpox is controlled. (c) For proper coverage, there should be one primary health centre for a population of 50,000; (d) Each primary health centre should be divided into 16 sub-centres each having a population of about 3,000 to 5,000 depending upon topography and means of communication; (e) Each (1) centre to be staffed by a team of one male and one female health worker; (f) There should be a male health supervisor to supervise the work of 3 to 4 female health workers; (g) A female health supervisor to supervise the work of 4 female health workers; (h) The present-day lady health visitors to be designated as female health supervisors and (j) The doctor in charge of a primary health centre should have the overall charge of all the supervisors and health workers in his area. The recommendations of the Kartar Singh Committee were accepted by the Government of India to be implemented in a phased manner during the Fifth Five Year Plan.

8. Srivastav committee, 1975 (20, 21)

The Government of India in the Ministry of Health and Family Planning had in November 1974 set up a "Group on Medical Education and Support Manpower" popularly known as the Srivastav Committee. (1) to devise a suitable curriculum for training a cadre of health assistants so that they can serve as link between the quatile medical practitioners and the multipurpose workers, thus forming an effective team to deliver health care, family welfare and nutritional services to the people; (2) to suggest steps for improving the existing medical educational process as to provide due emphasis on the problems particularly relevant to national requirements, and (3) to make any other suggestions to realise the above objectives and matters incidental thereto.

The Group submitted its report in April 1975. It recommended immediate action for: (1) creation of bands of para-professional and semi-professional health workers from within the community itself-(e.g., school teachers, postmasters, grain servals) to provide simple, promotive, preventive and creative health services needed by the community; (2) establishment of 2 cadres of health workers, namely--multipurpose health workers and health assistants between the community level workers and doctors at the PHC, (3) development of a "Referral Services Complex" by establishing proper linkages between the PHC and higher level referral and service centres, viz taluka/tehsil, district, regional and medical college hospitals, and (4) establishment of a Medical and Health Education Commission for planning and implementing the reforms needed in health and medical education on the lines of the University Grants Commission.

The Committee felt that by the end of the Sixth Plan, one male and one female health worker should be available for every 5,000 population. Also, there should be one male and female health assistant for 2 male and 2 female health workers respectively. The health assistants should be located at the sub-centre, and not at the PHC.

9. Rural health scheme, 1977

The most important recommendation of the Srivastav Committee was that primary health care should be provided within the community itself through specially trained

workers so that the health of the people is placed in the hands of the people themselves.

The basic recommendations of the Committee were accepted by the Government in 1977, which led to the launching of the Rural Health Scheme. The programme of training of community health workers was initiated during 1977-78. Steps were also initiated (a) for involvement of medical colleges in the total health care of selected PHCs with the objective of revitalising medical education to the needs of rural people; and (b) reorientation training of multipurpose workers engaged in the control of various communicable disease programmes into unipurpose workers. This "Plan of Action" was adopted by the Joint Meeting of the Central Council of Health and Central Family Planning Council held in New Delhi in April 1976 (22).

A working group on Health was constituted by the Planning Commission in 1986 with the Secretary, Ministry of Health and Family Welfare, as its Chairman, to identify, in programme terms, the goal for Health for All by 2000 AD and to outline with that perspective, the specific programmes for the sixth Five Year Plan.

The Working Group, besides identifying and setting out the broad approach to health planning during the sixth Five Year Plan, had also evolved fairly specific indices and targets to be achieved in the country by 2000 AD.

PLANNING COMMISSION

The Government of India set up a Planning Commission in 1950 to make an assessment of the material, capital and human resources of the country, and to draft developmental plans for the most effective utilization of these resources. In 1957, the Planning Commission was provided with a "Respective Planning Division which makes projections into the future over a period of 20 to 25 years. The Planning Commission consists of a Chairman, Deputy Chairman and 5 members. The Planning Commission works through 3 major divisions-- Programme Advisers, General Secretariat and Technical Division which are responsible for scrutinizing and analyzing various schemes and projects to be incorporated in the Five Year Plans. Over the years, the Planning Commission has been formulating successive Five Year Plans. By its terms of reference, the Planning Commission also reviews from time to time the progress made in various directions and to make recommendations to Government on problems and policies relevant to the pursuit of rapid and 'balanced' economic development. The planning process was decentralised towards Decentralised District Planning by the year 2000.

NITI AAYOG

Government of India has established NITI Aayog (National Institution for Transforming India) to replace Planning Commission on 1st January 2015. It will seek to provide a critical directional and strategic input into the development process; NITI Aayog will emerge as a "think-tank" that will provide Governments at the central and state levels with relevant strategic and technical advice across the spectrum of key elements of policy. In addition, the NITI Aayog will monitor and evaluate the implementation of programmes, and focus on technology upgradation and capacity building.
HEALTH SECTOR PLANNING

Since "health" is an important contributory factor in the utilization of manpower, the Planning Commission gave considerable importance to health programmes in the Five Year Plans. For this reason the health sector has been divided into the following sub-sectors (25),

1. Water supply and sanitation
2. Control of communicable diseases
3. Medical education, training and research
4. Medical care including hospitals, dispensaries and primary health centres
5. Public health services
6. Family planning; and
7. Indigenous systems of medicine.

All the above sub-sectors have received due consideration in the Five Year Plans. However, the emphasis has changed from Plan to Plan depending upon the felt-needs of the people and technical considerations. To give effect to a better coordination between the Centre and State Governments, a Bureau of Planning was constituted in 1965 in the Ministry of Health, Govt. of India. The main function of this Bureau is compilation of National Health Five Year Plans. The Health Plan is implemented at various levels, e.g., Centre, State, District, Block and Village.

FIVE YEAR PLANS (26, 27, 28)

The five year plans were conceived to re-build rural India, to lay the foundations of industrial progress and to secure the balanced development of all parts of the country. Recognising "health" as an important contributory factor in the utilisation of manpower and the uplifting of the economic conditions of the country, the Planning Commission gave considerable importance to health programmes in the five year plans. The broad objectives of the health programmes during the five year plans have been:

1. Control or eradication of major communicable diseases
2. Strengthening of the basic health services through the establishment of primary health centres and subcentres
3. Population control;
4. Development of health manpower resources.

Twelfth Five Year Plan (2012-2017)

The health of a nation is an essential component of development, vital to the nation's economic growth and internal stability. Assuring a minimal level of health care to the population is critical to the development process.

Since independence, India has built up a vast health infrastructure and health personnel at primary, secondary and tertiary care in public, voluntary, and private sectors. For producing skilled human resources, a number of medical and paramedical institutions including Ayurveda, Yoga and Naturopathy, Unani, Siddha and Homeopathy (AYUSH) institutions have been set up.

Considerable achievements have been made over the last six decades in the efforts to improve health standards, such as life expectancy, child mortality, infant mortality, and maternal mortality. Smallpox, guinea worm, poliomyelitis have been eradicated. Nevertheless, problems abound. Malnutrition affects a large proportion of children. An unacceptable high proportion of the population continues to suffer and die from new diseases that are emerging apart from continuing and new threats posed by the existing ones.

Pregnancy and childbirth related complications also contribute to the suffering and mortality. The strong link between poverty and ill-health needs to be recognized. The onset of a long and expensive illness can drive the non-poor into poverty. Ill-health creates immense stress even among those who are financially secure. The country has to bear the costs of health services. The challenge of quality health services in remote rural regions has to be urgently met. Given the current inequities in health care, it is clear that there is a need to develop public health care into an accountable, accessible, and affordable system of quality services during the Twelfth Five Year Plan.

The Union Govt. makes a special effort to strengthen the health system in the 11th Plan to ensure the reach of health care and work towards the long-term objective of establishing a system of Universal Health Coverage in the country. This means that each individual would have access to a defined essential package of medical services and treatment at an affordable price, which should be entirely free for a large percentage of the population. The High Level Expert Group (HLEG) has defined the Universal Health Coverage as "Ensuring equitable access for all Indian citizens in any part of the country, regardless of income level, social status, gender, caste or religion, to affordable, accountable and appropriate, assured quality health services (preventive, curative, curative and rehabilitative) as well as services addressing wider determinants of health delivered to individuals and households, with the government being the guarantor and enabler, although not necessarily the only provider of health and related services" (29). This definition affirms that the system must be available for all who want it, though some, typically the upper income groups, may opt out.

In order to achieve health goals, the universal health coverage (UHC) must build on universal access to services that are considered essential, such as safe drinking water and sanitation, wholesome nutrition, basic education, safe housing and hygienic environment. Therefore, it may be necessary to realign the goal of UHC in two parallel steps:

1. Clinical services at different levels, defined in an Essential Health Package, which the government would finance and ensure the 12th mission through the public health system, supplemented by contracted-in private providers;
2. The universal provision of high impact, preventive and public health interventions which the government would universally provide within the 12th Five Year Period (as shown in Table 2). The UHC would take almost two plan periods for realization.

Outcome Indicators for Twelfth Plan (29)

The Twelfth Plan will work towards national health outcome goals with following target health indicators:

1. Reduction of Infant Mortality Rate (IMR) to 25 at the recent rate of decline of 5 per cent per year, India is projected to have an IMR of 36 by 2015 and 32 by 2017. An achievement of the MDG of reducing IMR to 27 by 2015 would result in the acceleration of this historical rate of decline. If this accelerated rate is sustained, the country can achieve an IMR of 25 by 2017.
2. Reduction of Maternal Mortality Ratio (MMR) to 100:

   a. Reduction of Maternal Mortality Ratio (MMR) to 100:

   At the recent rate of decline of 5.8 per cent per annum India is projected to have an MMR of 139 by 2015 and 123 by 2017. An achievement of the Millennium Development Goal (MDG) of reducing mortality to 109 by 2015 would require an accelerated rate of decline, the country can achieve an MMR of 100 by 2017.
TABLE 2
List of preventive and public health interventions funded and provided by government

1. Full immunization among children under three years of age, and pregnant women.
2. Full immunization, natal and postnatal care.
3. Skilled birth attendance with facility for emergency obstetric care.
4. Iron and Folic acid supplementation for children, adolescent girls and pregnant women.
5. Regular treatment of intestinal worms, especially in children and reproductive age women.
6. Universal use of iodine and iron fortified salt.
7. Vitamin A supplementation for children aged 9 to 59 months.
8. Access to a basket of contraceptives, and safe abortion services.
9. Preventive and promotive health educational services, including information on hygiene, hand-washing, dental hygiene, use of potable drinking water, avoidance of tobacco, alcohol, high calorie diet and obesity; need for regular physical exercise, use of helmets on two-wheelers and seat belts; advice on limitation of breast-feeding within one hour of birth and exclusively up to six months of age, and complimentary feeding thereafter; adolescent sexual health, awareness about RTI/STD; need for screening for NCDs and common cancers for those at risk.
11. Community based care for sick children, with referral of cases requiring higher levels of care.
12. HIV testing and counselling during antenatal care.
13. Free drugs to pregnant HIV positive mothers to prevent mother to child transmission of HIV.
14. Malaria prophylaxis, using Long Lasting Insecticidal Treated Nets (LLIN), diagnosis using Rapid Diagnostic Kits (RDK), and appropriate treatment.
15. School check-up of health and wellness, followed by advice, and treatment if necessary.
17. Diagnosis and treatment of Tuberculosis, Leprosy including Drug and Multi-drug Resistant cases.
18. Vaccines for hepatitis B and C for high risk groups.
19. Patient transport systems including emergency response ambulance services of the 'dia 108' model.

3. Reduction of Total Fertility Rate (TFR) to 2.1 : India is on track for the achievement of a TFR target of 2.1 by 2017, which is necessary to achieve net replacement level of fertility, and realise the long cherished goal of the National Health Policy, 1983 and National Population Policy of 2000.

4. Prevention and reduction of under-nutrition in children under 5 years to half of NFHS-3 (2005-06) levels: Underweight children are at an increased risk of mortality and morbidity. At the current rate of decline, the prevalence of under-weight children is expected to be 29 per cent by 2015, and 27 per cent by 2017. An achievement of the MDG of reducing undernourished children under 5 years to 26 per cent by 2015 would require an acceleration of this historical rate of decline. The country needs to achieve a reduction in below 5 year child under-nutrition to half of 2005-06 (NFHS) levels by 2017. This particular health outcome has a very direct bearing on the broader commitment to security of life, as do MMR, IMR, anaemia and child sex ratio.

5. Prevention and reduction of anaemia among women aged 15-19 years to 28 per cent: Anaemia, as underlying determinant of maternal mortality and low birth weight, is preventable and treatable by a very simple intervention. The prevalence of anaemia needs to be steeply reduced to 28 per cent by the end of the twelfth plan.

6. Raising child sex ratio in the 0-6 years age group from 914 to 950: Like anaemia, child sex ratio is another important indicator which has been showing a deteriorating trend, and needs to be targeted for priority attention.

7. Prevention and reduction of burden of communicable and non-communicable diseases (including mental illnesses) and injuries: State wise and national targets for each of these conditions will be set by the Ministry of Health and Family Welfare as robust systems are put in place to measure their burden. Broadly, the goals of communicable diseases shall be as indicated in Table 3.

8. Reduction of poor households' out-of-pocket expenditure: Out-of-pocket expenditure on health care is a burden on poor families, leads to impoverishment and is a regressive system of financing. Increase in public health spending to 1.97 per cent of GDP by the end of the twelfth plan, cost-free access to essential medicines in public facilities, regulatory measures proposed in the twelfth plan are likely to lead to increase in share of public spending. The twelfth plan measures will also aim to reduce out-of-pocket spending as a proportion of private spending on health.

Table 5 shows the investments in health and Family Welfare Programmes during different plan periods.

HEALTH SYSTEM IN INDIA

India is a Union of 29 States and 7 Union territories. Under the Constitution of India, the States are largely independent in matters relating to the delivery of health care to the people. Each State, therefore, has developed its own system of health care delivery, dependent on the Central Government. The Central responsibility consists mainly of policy making, planning, guiding, assisting, evaluating, and coordinating the work of the State Health Ministries, so that health services cover every part of the country, and so State laws behind for want of these services. The Health system in India has 3 main linka, i.e., Central, State and Local or peripheral.

1 - AT THE CENTRE

The official "organs" of the health system at the national level consist of: (1) The Ministry of Health and Family Welfare; (2) The Directorate General of Health Services; and (3) The Central Council of Health and Family Welfare.

1. Union Ministry of Health and Family Welfare

(1) ORGANIZATION

The Union Ministry of Health and Family Welfare is headed by a Cabinet Minister, a Minister of State and a Deputy Health Minister. These are political appointments. Currently, the Union Health Ministry has the following departments: (1) Department of Health and (2) Department of Family Welfare. The Health Department is headed by a Secretary to the Government of India as its executive head, assisted by joint secretaries, deputy secretaries and a large administrative staff. The Department of Family Welfare was created in 1960 within the Ministry of Health and Family Welfare. The Secretary to the Govt. of India in the Ministry of Health and Family Welfare is in overall charge of the Department of Family Welfare. He is assisted by an Additional Secretary & Commissioner (Family Welfare), and one Joint Secretary.

(2) FUNCTIONS

The functions of the Union Health Ministry are set out in the seventh schedule of Article 246 of the Constitution of India under (a) the Union list and (b) the Concurrent list.

(a) Union list: The functions given in the Union list are:
(1) International health relations and administration of port quarantine (2) Administration of central institutes such as the All India Institute of Hygiene and Public Health, Kolkata; National Institute for the Control of Communicable Diseases, Delhi, etc. (3) Promotion of research through research centres and other bodies (4) Regulation and development of medical, pharmaceutical, dental and nursing professions (5) Establishment and maintenance of drug standards (6) Census, and collection and publication of

</table>
other statistical data (7) Immigration and emigration
(8) Regulation of labour in the working of mines and oil
fields and (9) Coordination with States and with other
ministries for promotion of health.

(b) Concurrent list: The functions listed under the
concurrent list are the responsibility of the Government of
India and the Government of the State.

The Centre and the States have simultaneous powers of legislation; the powers of the latter
are restricted to the framework of such legislation as may be
undertaken by the Centre. The concurrent list includes:

1) Preventions of extension of communicable diseases
   from one unit to another (2) Prevention of adulteration of
   foodstuffs (3) Control of drugs and poisons (4) Vital
   statistics (5) Labour Welfare (6) Ports other than major
   (7) Economic and social planning, and (8) Population
   control and Family Planning.

2. Directorate General of Health Services

(a) ORGANIZATION: The Director General of Health
   Services is the principal advisor to the Government in
   both medical and public health matters. He is assisted by an
   additional Director General of Health Services, a team of
   deputies and a large administrative staff. The Directorate
   comprises of three main units, e.g., medical care and
   hospitals, public health and general administration.

(b) FUNCTIONS: The GENERAL functions are surveys,
   planning, coordination, programming and appraisal of all
   health matters in the country. The SPECIFIC functions are
   (1) International health relations and quarantine: All
   the major ports in the country (Kolkata, Visakhapatnam,
   Chennai, Cochin, Mumbai, Kandy) and international air
   ports (Mumbai—Santa Cruz, Kolkata—Dum Dum, Chennai—
   Meenambakkam, Tiruchirappalli, Delhi—Palam) are directly
   controlled by the Directorate General of Health Services.
   All matters relating to the obtaining of assistance from
   International agencies and the coordination of their
   activities in the country are undertaken by the Directorate
   General of Health Services. (2) Control of drug standards:
   The Drugs Control Organization is part of the Directorate
   General of Health Services, and is headed by the Drugs
   Controller. Its primary function is to lay down and enforce
   standards and control the manufacture and distribution of
   drugs through both Central and State Government Officers.
   The Drug Act (1940) vests the Central Government with the
   powers to test the quality of imported drugs. (3) Medical
   store depots: The Union Government runs medical store
   depots at Mumbai, Chennai, Kolkata, Karnal, Guwahati and
   Hyderabad. These depots supply the civil medical
   requirements of the Central Government and of the various
   State Governments. These depots also handle supplies from
   foreign agencies. The Medical Stores Organization
   endeavours to ensure the highest quality, cheapest bargain
   and prompt supplies. (4) Post-graduate training: The
   Directorate General of Health Services is responsible for the
   administration of national institutes, which also provide
   post-graduate training to different categories of health
   personnel. Some of these institutes are: the All India
   Institute of Hygiene and Public Health at Kolkata, All India
   Institute of Mental Health at Bangalore, College of Nursing
   at Delhi, National Tuberculosis Institute at Bangalore,
   National Institute of Communicable Diseases at Delhi,
   Central Research Institute at Kasauli, National Institute of
   Health and Family Welfare at Delhi, etc. (5) Medical
   education: The Central Directorate is directly in charge of
   the following medical colleges in India: the Lady Hardinge,
   the Maulana Azad and the medical colleges at浦路痴hy, and Goa. Besides these, there are many medical colleges in
   the country which are guided and supported by the Centre.
   (6) Medical Research: Medical research in the country is
   organized largely through the Indian Council of Medical
   Research, founded in 1911 in New Delhi. The Council plays a
   significant role in aiding, proposing and coordinating
   scientific research on human diseases, their causation,
   prevention and cure. The research work is done through the
   Council's several permanent research institutes: research
   units, field surveys and a large number of ad-hoc research
   enquiries financed by the Council. It maintains Cancer
   Research Centre, Tuberculosis Chemotherapy Centre at
   Chennai, Virus Research Centre at Poona, National Institute
   of Nutrition at Hyderabad and Blood Group Reference
   Centre at Mumbai. The funds of the Council are wholly
   derived from the budget of the Union Ministry of Health.
   (7) Central Govt. Health Scheme: (8) National Health
   Programmes: The various national health programmes for
   the eradication of malaria and for the control of tuberculosis,
   filaria, leprosy, AIDS and other communicable diseases
   involve expenditure of crores of rupees. Health
   programmes of this kind can hardly succeed without the
   help of the Central Government. The Central Directorate
   plays a very important part in planning, guiding and
   coordinating all the national health programmes in the
   country. (9) Central Health Education Bureau: An
   outstanding activity of this Bureau is the preparation of
   education material for creating health awareness among
   the people. The Bureau offers training courses in health
   education to different categories of health workers.

   (10) Health Intelligence: The Central Bureau of Health
   Intelligence collects, compiles, analyses and distributes
   the data, information and statistics which are of importance
   to the Health Services in India. The Bureau prepares
   summaries, analytical reports, and research reports, based
   on the work of International bodies, such as WHO, UNICEF
   and FAO. The Central Bureau of Health Intelligence
   provides all necessary intelligence and data on health
   and related sciences by collection, dissemination and
   exchange of information.

3. Central Council of Health

   A large number of health subjects fall in the Concurrent
   list which calls for continuous consultation, mutual
   understanding and cooperation between the Centre and the
   States. The Central Council of Health was set up by a
   Presidential Order on 9 August, 1952 under Article 263 of
   the Constitution of India for promoting coordinated and
   concerted action between the Centre and the States in the
   implementation of all the programmes and measures
   pertaining to the health of the nation. The Union Health
   Minister is the Chairman and the State Health Ministers
   are the members.

   FUNCTIONS: The functions of the Central Council of
   Health are: (1) To consider and recommend broad outlines
   of policy in regard to matters concerning health in all its
   aspects, e.g., the provision of remedial and preventive
   care, environmental hygiene, nutrition, health education
   and the promotion of facilities for training and research.

   (2) To make proposals for legislation in fields of activity
   relating to medical and public health matters and to lay
   down the pattern of development for the country as a whole.

   (3) To make recommendations to the Central Government
regarding distribution of available grants-in-aid for health purposes to the States and to review periodically the work accomplished in different areas through the utilisation of these grants-in-aid. (4) To establish any organisation or organisations invested with appropriate functions for promoting and maintaining a closer coordination between the Central and State Health administrations.

II – AT THE STATE LEVEL

Historically, the first milestone in State health administration was the year 1919, when the States (then known as provinces) obtained autonomy, under the Montagu-Chelmsford reforms, from the Central Government, in matters of public health. By 1921–22, all the States had created some form of public health organization. The Government of India Act, 1935 gave further autonomy to the States. The health subjects were divided into three groups: federal, concurrent and state. The “state” list which became the responsibility of the State included provision of medical care, preventive health services and pilgrimages within the State. The position has largely remained the same, even after the new Constitution of India came into force in 1950. The State is the ultimate authority responsible for the health services operating within its jurisdiction.

State health administration

At present there are 29 States in India, with each state having its own health administration. In all the States, the management sector comprises the State Ministry of Health and a Directorate of Health.

1. State Ministry of Health

The State Ministry of Health is headed by a Minister of Health and Family Welfare and a Deputy Minister of Health and Family Welfare. In some States, the Health Minister is also in charge of other portfolios. The Health Secretariat is the official organ of the State Ministry of Health and is headed by a Secretary who is assisted by Deputy Secretaries, Under Secretaries and a large administrative staff. The Secretary is a senior officer of the Indian Administrative Service. The Bhore Committee (1946) recommended that the Director of Health Services should also be Secretary to the State Government to facilitate administration, but this recommendation has not been implemented.

2. State Health Directorate

For a long time, two separate departments, medical and public health, were functioning in the States; the heads of these departments were known as Surgeon General and Inspector General of Civil Hospitals and Director of Public Health respectively. The Bhore Committee (1946) recommended that the medical and public health organizations should be integrated at all levels and therefore, should have a single administrative officer for the curative and preventive departments of health. West Bengal led the process of integrating health services at the State level by creating a post of the Director of Health Services in August 1947; the process was completed by Maharashtr in May 1970.

The Director of Health Services (known in some States as Director of Medical and Health Services) is the chief technical adviser to the State Government on all matters relating to medicine and public health. He is also responsible for the organization and direction of all health activities. With the advent of family planning as an important programme, the designation of Director of Health Services has been changed in some States and is now known as Director of Health and Family Welfare. A recent development in some States is the appointment of a Director of Medical Education in view of the increasing number of medical colleges. Some experts feel that there is no justification for the removal of medical education from general health services under the Director of Health Services. The health services and training institutions should develop into one logical whole designed to an end – the protection of the health of the people. The Director of Health and Family Welfare is assisted by a suitable number of deputies and assistants. The Deputy and Assistant Directors of Health may be of two types – regional and functional. The Regional Directors inspect all the branches of public health within their jurisdiction, irrespective of their speciality. The Functional Directors are usually special divisional officers in branches of public health such as mother and child health, family planning, nutrition, tuberculosis, leprosy, health education etc. The Public Health Engineering Organization in most States is part of the Public Works Department of the State Government. It has been recommended by the experts in the public health that the public health engineering organization in every State should be part of the State Health Department, and that the Chief Engineer of Public Health should have the status of an Additional Director of Health Services.

III – AT THE DISTRICT LEVEL

The District

The principal unit of administration in India is the district under a Collector. There are 614 (year 2007) districts in India. There is no “average” district that is the district varies widely in area and population. Within each district again, there are 6 types of administrative areas

1. Sub-divisions
2. Tahsils (Talukas)
3. Community Development Blocks
4. Municipalities and Corporations
5. Villages
6. Panchayats

Most districts in India are divided into two or more sub-divisions, each in charge of an Assistant Collector or sub-collector. Each division is again divided into tahsils (talukas), in charge of a Tahsildar. A tahsil usually comprises between 200 to 600 villages. Since the launching of the Community Development Programmes in India in 1952, the rural areas of the district have been organized into Blo-ba, known as Community development blocks, the area of which may or may not coincide with a tahsil. The block is a unit of rural planning and development, and comprises approximately 100 villages and about 80,000 to 1,20,000 population, in charge of a Block Development Officer. Finally there are the village panchayats, which are institutions of rural local self-government.

The urban areas of the district are organized into the following institutions of local self-government:

1. Town area committees – (In areas with population ranging between 5,000 and 10,000)
2. Municipal Boards – (In areas with population ranging between 10,000 and 2 lakhs)
3. Corporations – (With population above 2 lakhs)
The Town area committee are like panchayats. They provide sanitary services. The Municipal Boards are headed by a Chairman/President, elected usually by the members. The term of a Municipal Board ranges between 3–5 years. The functions of a municipal board are: construction and maintenance of roads, sanitation and drainage, street lighting, water supply, maintenance of hospitals and dispensaries, education, registration of births and deaths, etc. Corporations are headed by Mayors. The councillors are elected from different wards of the city. The executive agency includes the Commissioner, the Secretary, the Engineer and the Health Officer. The activities are similar to those of the municipalities, but on a much wider scale.

Health organization

The Bhore Committee (1946) recommended integrated preventive and curative services at all levels and the setting up of a unified health authority in each district. Subsequent expert committees, appointed by the Government of India have also recommended the same. Since "health" is a state subject, there is no uniform "model" of a district health organization in India, each State developed its own pattern to suit its policy and convenience.

Under the Multi-Purpose Workers Scheme, it has been suggested to the States to have an integrated set-up at the district level by having a Chief Medical Officer with three Deputy CMOs (existing Civil Surgeons, District Health Officers and District Family Welfare Officers) with each of the Dy. CMOs being incharge of one-third of the district for all the Health, Family Welfare and MCH programmes. The recent Working Group on Health for All by 2000 AD, appointed by the Planning Commission, recommended that the District Hospitals should be converted into District Health Centres, each centre monitoring all preventive, promotive and curative services of one million population. It has been recommended that the district set-up should be reorganized on the basis of the number of primary health centres it comprises (23).

PANCHAYATI RAJ (32, 33)

The Panchayati Raj is a 3-tier structure of rural local self-government in India, linking the village to the district. The three institutions are:

1. Panchayat – at the village level
2. Panchayat Samiti – at the block level
3. Zilla Parishad – at the district level

The Panchayati Raj institutions are accepted as agencies of public welfare. All development programmes are channelled through these bodies. The Panchayati Raj institutions strengthen democracy at its root, and ensure more effective and better participation of the people in the government.

1. At the village level

The Panchayati Raj at the village level consists of:

(i) the Gram Sabha
(ii) the Gram Panchayat and
(iii) the Nyaya Panchayat

Gram Sabha: It is the assembly of all the adults of the village, which meets at least twice a year. The gram sabha considers proposals for taxation, discusses the annual programme and elects members of the gram panchayat.

Gram Panchayat: It is the executive organ of the gram sabha, and an agency for planning and development at the village level. Its strength varies from 15 to 30, and the population covered also varies widely from 5,000 to 15,000 or more. The members of the panchayat hold office for a period of 3 to 4 years. Elected panchayats have an elected President (Sarpanch or Sabha Sahab or Mukhiya) and a Vice-President and a Panchayat Secretary. The powers and functions of the Panchayat Secretary are very wide – they cover the entire field of civic administration, including sanitation and public health; and all social and economic development of the village.

2. At the Block level

The block consists of about 100 villages and a population of about 80,000 to 1,20,000. The Panchayat Raj agency at the block level is the Panchayat Samiti / Janpada Panchayat. The Panchayat Samiti consists of all Sarpanches (heads) of the village panchayats in the Block; MLAs, MPs residing in the block area; representatives of women; scheduled castes, scheduled tribes and cooperative societies. The Block Development Officer (BDO) is the ex-officio secretary of the Panchayat Samiti. The prime function of the Panchayat Samiti is the execution of the community development programme in the block. The funds provided by the Government for Stage I and Stage II development are channelled through the Panchayat Samiti. The Block Development Officer and his staff give technical assistance and guidance to the village panchayats engaged in development work.

3. At the District level

The Zilla Parishad / Zilla Panchayat is the agency of rural local self-government at the district level. The members of the Zilla Parishad include all heads of the Panchayat Samitis in the district; MPs, MLAs of the district; representatives of scheduled castes, scheduled tribes and women; and 2 persons of experience in administration, public life or rural development. The Collector of the district is a non-voting member. Thus, the membership of the Zilla Parishad is fairly large varying from 40 to 70.

The Zilla Parishad is primarily supervisory and coordinating body. Its functions and powers vary from state to state. In some states, the Zilla Parishads are vested with administrative functions. In Gujarat, the District Health Officer and the District Family Planning and MCH Officers are under the control of the Zilla Parishad.

RURAL DEVELOPMENT

Terms such as village improvement, rural upliftment, rural reconstruction and community development have been in vogue for many years to depict certain aspects of rural development. It is only during the last four decades that they have become comprehensive in content.

Community Development Programme

Community development was defined as "a process designed to create conditions of economic and social progress for the whole community with its active participation and the fullest possible reliance upon the community’s initiative" (34). The United Nations defined community development as "the process by which the efforts of the people themselves are united with those of governmental authorities to improve the economic, social and cultural conditions of communities, to integrate those
communities with the life of the nation and to enable them to contribute fully to national progress” (33).

A beginning was made in India in 1952 during the First Five Year Plan to involve the rural population in the process of planning their own welfare measures. A Programme known as the Community Development Programme was launched on 2nd October 1952 for the all-round development of the rural areas, where nearly 72 per cent of India’s population lives. The programme was hailed as “a programme of the people, for the people, by the people” to exterminate the three ills of poverty, disease and illiteracy.

Under the Community Development Programme, the rural areas of the country have been divided into Community Development Blocks – each Block comprising approximately 100 villages and a population of one lakh. There are about 6,000 Community Development Blocks in the country, each Block is headed by a Block Development Officer. Over the years, the CD Block has emerged as a permanent unit of rural planning and development.

The Community Development Programme was envisaged as a multi-purpose programme covering the following main activities – improvement of agriculture, improvement of communications, education, health and sanitation (through the establishment of primary health centres and sub-centres), improvement of housing through self-help, social welfare and training in rural arts, crafts and industries to local people.

Each Block passed through two stages of development – Stage I of 5 years intensive development followed by Stage II of another 5 years. The Centre Government supported the programme substantially by providing funds to the tune of Rs 12 lakhs during Stage I and Rs 5 lakhs during Stage II phases of development. At the end of 10 years, the Blocks entered post-stage II phase and their financial arrangements became the responsibility of the State Governments. The Block continues to be the permanent infrastructure for rural planning and development.

Although the Community Development Programme has made its own contribution to rural development, it has not succeeded in bringing about all-round development to rural areas and in eliminating rural poverty and unemployment. The hope that people would unite their efforts with those of the Government to build the village community on a pattern in which disparities in income and wealth would disappear was not realised. In fact, the benefits of the programme did not reach the weaker sections of the community.

Integrated Rural Development Programme (IRDP)

Another innovation in the continuous search for appropriate strategies to attack poverty is the IRDP. It was launched in April 1978 to eliminate rural poverty and improve the quality of life of the rural poor. The target families are generally agricultural labourers, small cultivators, village artisans and craftsmen. They are provided with resources and skills, bank loans and subsidies by the government. The IRDP is being implemented through District Rural Development Agency (DRDA).

During Ninth Five Year Plan it was implemented through an integrated approach under which the existing schemes of Training of Rural Youth for Self Employment (TRYSEM) and Supply of Improved Toolkits to Rural Artisans (SITRA), Development of Women and Children in Rural Areas (DWCRD) and Ganga Kalyan Yojana (GKY) were merged in to IRDP. There will be a strategic shift from an individual beneficiary approach to formation of Self-Help Groups. This approach will focus on the identification of few specified viable activities based on the local resources and occupational skills of the people of that area.

The Village Level Worker

The village level worker (gram sevak) is the key person responsible for transforming the economic and social life of the people. Each gram sevak is in charge of 10 villages and attends to 5 or 6 thousand people. He lives with the people and keeps in close touch with them and their families. He proves into their “felt-needs” and seeks to arouse in them interest in all-round family and village development. In short, he functions as a multi-purpose worker and a link between the people and governmental agencies.

EVALUATION OF HEALTH SERVICES

Health services have become complex. There has been a growing concern about their functioning both in the developed and developing countries. Questions are raised about the quality of medical care (35), utilization and coverage of health services (36), benefits to community health in terms of morbidity and mortality reduction (37) and improvement in the health status of the recipients of care. An evaluation study addresses itself to these issues.

General steps of evaluation

The basic steps involved are as follows:

1. Determine what is to be evaluated
2. Establish standards and criteria
3. Plan the methodology to be applied
4. Gather information
5. Analyse the results
6. Take action
7. Re-evaluate

1. Determine what it is to be evaluated

Generally speaking, there are three types of evaluation:

(a) Evaluation of "structure": This is evaluation of whether facilities, equipment, manpower and organization meet a standard accepted by experts as good.

(b) Evaluation of "process": The process of medical care includes the problems of recognition, diagnostic procedures, treatment and clinical management, care and prevention. The way in which the various activities of the programme is carried out is evaluated by comparing with a predetermined standard. An objective and systematic way of evaluating the physician (or nurse) performance is known as "Medico (or Nursing) Audit" (38).

(c) Evaluation of "outcome": This is concerned with the end results, that is, whether persons using health services experience measurable benefits such as improved survival or reduced disability. The traditional outcome components are the "5 Ds" of ill-health, viz. disease, discomfort, dissatisfaction, disability and death.

2. Establishment of standards and criteria

Standards and criteria must be established to determine how well the desired objectives have been attained. Naturally such standards are a prerequisite for evaluation. Standards and criteria must be developed in accordance with the focus of evaluation—structure or process criteria: e.g., physical facilities and equipment; process criteria: e.g., every prenatal
mother must receive 6 check-ups; every laboratory technician must examine 100 blood smears, etc; outcome criteria: e.g., alterations in patient health status (cured, death, disability); or behavior resulting from health care satisfaction, dissatisfaction; or the educational process (e.g., cessation of smoking, acceptance of a small family norm), etc.

3. Planning the methodology

A format in keeping with the purpose of evaluation must be prepared for gathering information desired. Standards and criteria must be included at the planning stage.

4. Gathering information

Evaluation requires collection of data or information. The type of information required may include political, cultural, economic, environmental and administrative factors influencing the health situation as well as morality and morbidity statistics. It may also concern health and related socio-economic policies, plans and programmes as well as the extent, scope and use of health systems, services and institutions (39). The amount of data required will depend on the purpose and use of the evaluation.

5. Analysis of results

The analysis and interpretation of data and feedback to all individuals concerned should take place within the shortest time feasible, once information has been gathered. In addition, opportunities should be provided for discussing the evaluation results.

6. Taking action

For evaluation to be truly productive, emphasis should be placed on actions - actions designed to support, strengthen or otherwise modify the services involved. This may also call for shifting priorities, revising objectives, or development of new programmes or services to meet previously unidentified needs.

7. Re-evaluation

Evaluation is an on-going process aimed mainly at rendering health activities more relevant, more efficient and more effective.

Elements of evaluation

Evaluation is perhaps the most difficult task in the whole area of health services. The components of the evaluation process are:

(a) Relevance: Relevance or requisite link to the appropriateness of the service, whether it is needed at all (40). If there is no need, the service can hardly be of any value. For example, vaccination against smallpox is now irrelevant because the disease no longer exists.

(b) Adequacy: It implies that sufficient attention has been paid to certain previously determined courses of action. For example, the staff allocated to a certain programme may be described as inadequate if sufficient attention was not paid to the quantum of work-load and targets to be achieved.

(c) Accessibility: It is the proportion of the given population that can be expected to use a specified facility, service, etc. The barriers to accessibility may be physical (e.g., distance, travel, time); economic (e.g., travel cost, fee charged); or social and cultural (e.g., caste or language barrier) (41).

(d) Acceptability: The service provided may be acceptable, but not acceptable to all, e.g., male sterilization, screening for renal cancer (42).

(e) Effectiveness: It is the extent to which the underlying problem is prevented or alleviated. Thus it measures the degree of attainment of the predetermined objectives and targets of the programme, service or institution - expressed, if possible, in terms of health benefits, problem reduction or, in an improvement of an unsatisfactory health situation. The ultimate measures of effectiveness will be the reduction in morbidity and mortality rates (43).

(f) Efficiency: It is a measure of how well resources (money, men, material and time) are utilized to achieve a given effectiveness. The following examples will illustrate: the number of immunizations provided in an year as compared with an accepted norm; the percentage of bed occupancy, cost per day in hospital, cost per patient treated, etc (43, 44, 45).

(g) Impact: It is an expression of the overall effect of a programme, services or institution on health status and socio-economic development. For example, as a result of malaria control in India, not only the incidence of malaria dropped down, but all aspects of life-agricultural, industrial and social-showed an improvement. If the target of 100 per cent immunization has been reached, it must also lead to a reduction in the incidence of diarrhoeal diseases.

Planning and evaluating must be viewed as a continuous interactive process, leading to continual modification both of objectives and plans. Successful evaluation may also depend upon whether the means of evaluation were built into the design of the programme before it was implemented (46).

HISTORY OF PUBLIC HEALTH IN INDIA

1. Early History

India has one of the most ancient civilizations in recorded history. Thousands of years before the Christian era, there existed a civilization in the Indus Valley, known as the Indus Valley Civilization. Excavations in the Indus Valley (e.g., Mohenjodaro and Harappa), showed relics of planned cities with drainage, houses and public baths built of baked bricks suggesting the practices of environmental sanitation, by ancient people as far back as 3,000 B.C. India was invaded by the Aryans around 1,400 B.C. It was probably during this period, the Ayurveda and the Siddha systems of medicine came into existence. Ayurveda or the Science of Life developed a comprehensive concept of health. The Maitri Samhita prescribed rules and regulations for personal health, dietetics and hygienic ritual at the time of birth and death, and also emphasised the unity of the physical, mental and spiritual aspects of life (47). Sarve jana Sukhino Bhavantu (May all men be free from disease and may all be healthy) was an ancient saying of the Indian sages. This concept of happiness has its roots in the ancient Indian philosophy of life, which conceived the oneness and unity of all people, wherever they lived.

The Post-Vedic period (600 B.C.-600 A.D.) was dominated by the religious teachings of Buddhism and Jainism. Medical education was introduced in the ancient universities of Taxila and Nalanda, leading to the titles of
Pranacharya and Pranativitara (47). A hospital system was developed during the reign of Rakhula Sanjitya (son of the Buddha) for men, women and animals and the system was continued and expanded by King Ashoka.

The next phase in Indian history (650–1850 A.D.) witnessed the rise and fall of the Moghul empire. The Muslim rulers introduced into India around 1,000 A.D. the Arabic system of medicine, popularly known as the Unani system, the origin of which is traced to Greek medicine. The Unani system since then became part of Indian medicine. With changes in the political conditions in India, the torch which was lighted thousands of years ago by the ancient sages grew dim, medical education and medical services became static, and the ancient universities and hospitals disappeared.

2. Public Health in British India (14, 15, 47, 48, 49)

By the middle of the 18th Century, the British had established their rule in India which lasted till 1947. The significance of the history of public health during this period is given below in chronological order:

1757 The British had established their rule in India. The civil and military services were established.
1825 The Quaranite Act was promulgated.
1859 A Royal Commission was appointed to investigate the causes of the extremely unsatisfactory condition of health in the British Army stationed in India. The Commission recommended the establishment of a Commission of Public Health in every presidency and pointed out the need for the protection of water supplies, construction of drains and prevention of epidemics in the civil population for safeguarding the health of the British Army.
1864 Sanitary Commissioners were appointed in the three major provinces—Bombay, Madras and Bengal. The Civil Surgeons/District Medical Officers became ex-officio District Health Officers.
1869 A Public Health Commissioner and a Statistical Officer were appointed with the Government of India.
1873 A Birth and Death Registration Act was promulgated.
1880 The Vaccination Act was passed.
1881 The first Indian Factories Act was passed; the first all-India Census was taken.
1885 The Local Self-Government Act was passed; Local Bodies came into existence.
1888 The Government of India directed that sanitation should be looked after by the local bodies, but no local public health staff was created to look after sanitation.
1896 A severe epidemic of plague occurred in India which awakened the Government to the urgent need of improving public health. The Plague Commission was appointed.
1897 The Epidemic Diseases Act was promulgated.
1904 The Plague Commission in its report recommended the reorganisation and expansion of public health departments and establishment of laboratory facilities for research, and production of vaccines and sera.
1909 The Central Malaria Bureau was founded at Kasauli.

1911 The Indian Research Fund Association (now I.C.M.R.) was established for the promotion of research.
1912 The Government of India decided to help the local bodies with grants, and also sanctioned the appointment of Deputy Sanitary Commissioners and Health Officers.
1918 The Lady Reading Health School, Delhi was established. The Nutrition Research Laboratory was established at Calcutta.
1919 The Montague-Cheilmsford Constitutional Reforms led to the transfer of public health, sanitation and vital statistics to the provinces under the control of an elected minister. This was the first step towards decentralisation of health administration in India.

1920–21 Municipalities and Local Board Acts, containing legal provisions for the advancement of public health were passed in several provinces.
1930 The All India Institute of Hygiene and Public Health, Calcutta was established with aid from the Rockefeller Foundation. The Child Marriage Restraint Act (Barda Act) came into effect fixing the minimum age of marriage at 14 for girls and 18 for boys.
1931 A Maternity and Child Welfare Bureau was established under the Indian Red Cross Society.
1935 The Government of India Act, 1935 revitalised the 1919 Act, giving greater autonomy to the provinces. All the health activities in the country were grouped in three lists–federal, concurrent and provincial under the control of Central, Central–cum–Provincial and Provincial Governments respectively.

1937 The Central Advisory Board of Health was set up with the Public Health Commissioner as Secretary and representatives from the provinces and Indian States as members, to coordinate the public health activities in the various provinces.
1939 The Madras Public Health Act was passed, which was the first of its kind in India; the first Rural Health Training Centre was established at Simgur, near Calcutta with aid from the Rockefeller Foundation; the Tuberculosis Association of India was established.
1940 The Drugs Act was passed, and drugs were brought under control for the first time.

1943 The Health Survey and Development Committee (Bhore Committee) was appointed by the Government of India to survey the existing position in regard to health conditions and health organization in the country, and to make recommendations for the future development.

1946 The Bhore Committee submitted its report. The health of the nation was reviewed under (1) Public Health (2) Medical Relief (3) Professional Education (4) Medical Research and (5) International Health. The Committee recommended a short term and a long-term programme for the attainment of reasonable health services based on concepts of modern health practice.

3. Public Health in the Post-independence era

India became independent in 1947. For the first time in India's long history, a democratic regime was set up with its
economy geared to a new concept, the establishment of a "Welfare State". The burdens of improving the health of the people, and widening the scope of health services fell upon the national government. The Bhore Committee's report and recommendations became the basis for most of the planning and measures adopted by the national government. The significant events in the history of public health since India became free are as follows:

1947 Ministries of Health were established at the Centre and States. The posts of Director General, Indian Medical Service, and of Public Health Commissioner with the Government of India were integrated in the post of Director General of Health Services, who is the principal adviser to the Union Government on both medical and public health matters. This example was followed by many States. The posts of Surgeon General, the Director of Public Health and Inspector General of Hospitals were integrated in many States in the post of Director of Health Services.

1948 (1) India joined the World Health Organisation as a member state (2) The Employees State Insurance Act, 1948 was passed (3) The report of the Environmental Hygiene Committee was published.

1949 (1) The Constituent Assembly adopted the Constitution of India on 26 November, 1949. Article 246 of the Constitution of India covers all the health subjects; these have been enumerated in the seventh schedule under three lists — Union List, Concurrent List and State List. Article 47 of the Constitution under the Directive Principles of State Policy states: "That the State shall regard the raising of the level of nutrition and the standard of living of its people and the improvement of public health as among its primary duties". (2) The post of Registrar General of India was created in the Ministry of Home Affairs (3) The South East Asia Regional Office of the W.H.O. was established in New Delhi (4) The Indian Research Fund Association was reconstituted into Indian Council for Research.

1950 The Constitution of India came into force in 1950 and India became a Republic. The Planning Commission was established in Government of India, which set to work immediately for drafting the first Five Year Plan.

1951 The launch of the first Five Year Plan, with a total outlay of Rs.2,356 crores. A sum of Rs.140 crores (5.9 per cent) was allotted for health programmes. The B.C.G. vaccination programme was launched in the country.

1952 (1) The Community Development Programme was launched on 5 October, 1952 for the all-round development of the rural areas. Provision of medical relief and preventive health services were part of the programme (2) The Central Council of Health was constituted with the Union Health Minister as Chairman and the Health Ministers of the States as members to coordinate health policies between the Central and State Governments. Primary health centres set up (3).

1953 (1); The National Malaria Control Programme was commenced as part of the first Five Year Plan (2) The National Extension Service Programme was started in various States as a permanent organization for rural development (3) A nation-wide family planning programme was started. (4) A committee was appointed to draft a Model Public Health Act for the States. (5) The Committee on Health Services (Central Government Health Scheme) was started at Delhi (6) The Central Textile Board was set up (7) The National Water Supply and Sanitation Programme was inaugurated (8) The National Leprosy Control Programme was started (9) VDRL antigen production was set up in Calcutta (10) The Prevention of Food Adulteration Act was passed by the Ford Foundation.

1954 (1) The National Filaria Control Programme was commenced as part of the first Five Year Plan (2) The Central Leprosy Teaching and Research Institute was established at Chhingbun, Madras (3) A Filaria Training Centre was established at Ernakulam, Kerala. (4) The Hindu Marriage Act prescribed the minimum age for marriage — 18 for boys and 15 for girls. (5) National TB sample survey commenced.

1955 (1) The Second Five Year Plan (1956–61) was launched with an outlay of Rs.4,800 crores, out of which Rs.225 crores (5.0 per cent) were earmarked for health programmes. (2) The Model Public Health Act was published. (3) The Central Health Education Bureau was established in the Union Health Ministry. (4) Director, Family Planning was appointed in the Union Health Ministry (5) The Demographic Training and Research Centre was established in Bombay. (6) The Tuberculosis Chemotherapy Centre was established in Madras (7) The Immoral Traffic Act was passed by Parliament (8) The Tamil Nadu Leprosy Control Pilot Project was established (9) The R.C.A. projects were established by the Union Health Ministry with aid from India.

1956 (1) Influenza pandemic swept the country (2) The Demographic Research Centres were established in Madras (3) The National Malaria Control Programme was converted into National Malaria Eradication programme (4) The Leprosy Advisory Committee of the Government of India was reconstituted. The National Development Council endorsed the recommendations made by the Balwantrai Mehta Committee on Panchayati Raj. A three-tier structure of local self-governing bodies from the village to the district was recommended for dispersal of power and responsibilities in the future. (4) The National TB Survey was completed.

1957 (1) The Mubalwar Committee was appointed by the Government of India to survey the progress made in the field of health since submission of the Bhore Committee's report, and to make recommendations for future development and expansion of health services (2) A Central Expert Committee was appointed under the ICMR to study the problems of cholera and malaria in India, which recommended measures for their eradication. (3) Rajashtan was the first State to introduce Panchayati Raj (4) The National Tuberculosis Institute at Bangalore was established. (5) The Nutrition Research Laboratory at Coimbatore was shifted to Hyderabad.

1958 (1) The School Health Committee was constituted.
by the Union Health Ministry to assess the present standards of health and nutrition of school children and suggest ways and means to improve them. (2) A National Nutrition Advisory Committee was constituted to tender advice regarding the nutrition programs adopted by the Government. (3) Pilot projects for the eradication of smallpox were initiated (4) Vital statistics were transferred to the National Health Survey, Ministry of Home Affairs, from the Directorate General Health Services.

1961
(1) The Third Five Year Plan (1961-66) was launched with an outlay of Rs.7,500 crores out of which Rs.342 crores (4.3 per cent) were provided for health programmes. (2) The Report of the Muladar Committee was published. (3) The Central Bureau of Health Intelligence was established.

1962
(1) The Central Family Planning Institute was established in Delhi by amalgamating the Family Planning Training Centre and Family Planning Communications and Action Research Centre. (2) The National Smallpox Eradication Programme was launched (3) The School Health Programme was initiated (4) The National Coiite control programme was launched (5) The District Tuberculosis Programme was formulated.

1963
(1) The Applied Nutrition Programme was launched by the Government of India with aid from UNICEF, FAO and WHO. (2) The Defence Institute of Physiology and Allied Sciences was set up. (3) The National Repealable Diseases (formerly Malaria Institute of India) was inaugurated. (4) The National Trachoma Control Programme was launched. (5) The name of "prophylactic Health Service Scheme" was changed to "Central Government Health Scheme". (6) Extended Family Planning Programmes were launched; emphasis in family planning was shifted from the clinic approach to "Extension approach". (7) The Chhada Committee estimated the need of Basic Health Workers for every 10,000 population. (8) A Drinking Water Board was set up.

1964
(1) The National Institute of Health Administration and Education was opened in collaboration with the Ford Foundation. (2) A Committee was set up by the Union Government under the chairmanship of Shantilal Shah, to study the question for legalising abortions.

1965
(1) Director, ICMR, recommended Lippes Loop as safe and effective for a mass programme (2) Reinforced Extended Family Planning was launched (3) Direct BCG vaccination without prior tuberculin test, on a house to house basis, was introduced.

1966
(1) A Committee of Health Secretaries under the chairmanship of Mukherjee, Secretary, Ministry of Health, Government of India was constituted to look into the minimum additional staff required for the primary health centres to take over the maintenance-work of malaria and smallpox (2) The Minister of Health was also appointed Minister for Family Planning (3) A separate department of Family Planning was constituted in the Union Ministry of Health to coordinate family planning programme at the Centre and States, (4) The population Council started the International Postpartum Family Planning Programme in 25 hospitals in 15 countries. Two of the centres were located in India – Delhi and Trivandum.

1967
(1) The Modhot Committee was constituted to review the working of the National Malaria Eradication Programme and recommended measures for improvement. (2) A Small Family Norm Committee was set up to recommend suitable incentives to those accepting the small family norm and practicing family planning. (3) The Central Council of Health recommended the levy of a health cess on patients attending hospitals: (i) a minimum charge of 10 Paise per patient and (ii) a minimum charge of 25 paise per day of hospital stay.

1968
(1) The Small Family Committee's Report was submitted. (2) A Bill of Registration of Births and Deaths was passed by the Parliament. (3) The Govt. of India appointed the Medical Education Committee to study all aspects of medical education in the light of national needs and resources.

1969
(1) The Fourth Five Year Plan (1969-74) was launched with an outlay of Rupees 16,774 crores, out of which Rs.8,480 crores were allocated to health and Rupees 3,156 crores to family planning. (2) The name of the Nutrition Research Laboratories was changed to National Institute of Nutrition. (3) Comprehensive legislation for control of river water pollution from domestic and industrial wastes was drafted to be introduced into Parliament. (4) The Central Births and Deaths Registration Act (1969) was promulgated. (5) The Report of the Medical Education Committee (1969) was submitted. The Committee recommended (1) that the total period for MBBS course should be 4½ years and one year for internship, which should include posting in a rural centre for a period of at least 3 months and (ii) the medical teaching and training should be orientated to produce a basic doctor, i.e., a doctor conversant with the basic health problems of rural and urban communities and who is able to play an effective role in primary health care.

1970
(1) The Drugs (Price Control) Order, 1970 was promulgated (2) All India Hospitals (Postpartum) Family Planning Programme was started (3) The Population Council of India was formed in April 1970 (4) Chittaranjan Mobile Hospitals (mobile training-cum-service unit) were installed on the 25th anniversary of Late C.R. Das on 5 Nov. 1970. The scheme envisages attachment of a mobile hospital to a suitable medical college in each State. (5) The Registration of Births and Deaths Act, 1969 came into force from 1 April (6) The name of the Demographic Trainging and Research Centre, Bombay was changed into International Institute for Population Studies.

1971
(1) The Family Planning Scheme (FPS) for industrial workers came into force (2) The Medical Termination of Pregnancy Bill, 1969 was passed by Parliament (3) An expert committee was appointed by the Govt. of India to draft suitable legislation on air pollution.

1972
(1) The Medical Termination of Pregnancy Act came into force on April 1, 1972 (2) National Service Bill
passed. It authorises the Government to compel medical personnel below 30 years of age to take up work in the countryside. (3) The National Nutrition Monitoring Bureau was set up under the Indian Council of Medical Research, with headquarters at the National Institute of Nutrition, Hyderabad. Regional units have also been established in the States.

1973

(1) The National Programme of Minimum Need was incorporated in the Fifth Five Year Plan. A provision of Rs. 2,803 crores was made for the programme, which covered elementary education, rural health, nutrition, rural roads and water supply, housing, slum improvement and rural electrification.

(2) The Government envisaged a scheme for setting up 30–bedded rural hospitals; one such hospital for every 4 primary health centres. (3) The Kastur Singh Committee submitted its report recommending the formation of a new cadre of health workers designated "Multi-purpose Health Workers" for the delivery of health, family planning and nutrition services to the rural communities, who will replace in course of time the basic health workers, family planning health assistants, auxiliary nurse-midwives, etc.

1974

(1) The Fifth Five Year Plan was launched on April 1, 1974 with a total outlay of Rs.35,411 crores of which Rs.37,250 crores were in the public sector and Rs.1,616 crores in the private sector. A sum of Rs.796 crores were allotted to health, and Rs.516 crores were allotted to education. (2) Regional Health Strategies for the "Second Indepth Evaluation Committee" and the "Consultative Committee of experts on the National Health Programmes" were submitted. Both the Committees suggested a "revised strategy" for malaria control. (3) The Union Cabinet designated 1974 as World Population Year. (4) Parliament enacted the Water (prevention and control of pollution) Act, 1974.

1975

1976

(1) Indian Factories Act of 1948 amended (2) The Prevention of Food Adulteration (Amendment) Act, 1975 came into force on 1 April, 1976 (3) The Equal Remuneration Act, 1975 was promulgated providing for equal wages for men and women for the same work of a similar nature. (4) The Union Health Ministry announced a new population policy. (5) The Central Council of Health proposed a 3-tier plan for medical care in villages. (6) The Indian Centre of Japan Leprosy Mission for Asia at Aga was handed over to the Indian authorities. (7) National Programme for Prevention of Blindness was formulated.

1977

(1) Eradication of smallpox declared in April by the International Commission (2) National Institute of Health and Family Planning formed. (3) Rural Health Scheme was launched. Training of community health workers was started. (4) Malaria eradication programme was put into operation (5) The 42nd Amendment of the Constitution made "Prevention of Malaria" a concurrent subject. (6) WHO adopted the goal of Health for All by 2000 AD (7) Rome scheme was launched.

1978

(1) Bill on Air Pollution introduced in the Lok Sabha (2) Parliament approved the Child Marry Restraint (Amendment) Bill, 1978 fixing the minimum age at marriage 21 years for boys and 18 years for girls. (3) EPI was launched (4) The Charter for Health Development in South East Asia was finalised and endorsed (5) Declaration of Alma Ata underlined the primary health care approach.

1979

(1) World Health Assembly endorsed the Declaration of Alma Ata on primary health care (2) The offices of family welfare and NMEP were merged and named as Regional Office for Health and Family Welfare.

1980

(1) On May 8, 1980, smallpox was officially declared eradicated from the entire world by World Health Assembly. (2) Sixth Five Year Plan (1980–1985) was launched.

1981

(1) The 1981 census was taken (2) WHO and Member Countries adopted the Global strategy for Health for All (3) Report of the Working Group on Health for All, set up by the Planning Commission, was published. (4) Efforts were made in the goal of providing safe drinking water and adequate sanitation for all by 1990, under the International Drinking Water Supply and Sanitation Decade, 1981–1990. (5) The Air (Prevention and Control of Pollution) Act of 1981 was enacted.

1982

(1) The New 20 Point Programme was announced. (2) The Govt. of India announced its National Health Policy.

1983

(1) India launched a National Plan of Action against avoidable disability, known as "IMPACT India". (2) National Leprosy Control Programme to be continued. (3) Medical Education Review Committee submitted its report. (4) National Health Policy was approved by the Working Manpower Compensation (Amendment) Act. 1984 came into force.

1984

(1) Bhopal gas tragedy, the worst ever industrial accident in history occurred on the night of Dec. 2/3 taking a toll of at least 3000 people and no fewer than 50,000 affected (2) The ESI (Amendment) Bill, 1984 was approved by Parliament (3) The Workers' Compensation (Amendment) Act, 1984 came into force from July 1. (4) Juvenile Justice Act 1986 came into force.

1985

(1) Health Five Year Plan (1985–1990) was launched (2) Universal Immunization Programme was launched (3) The Lepers Act, 1986 was repealed by Parliament (4) A separate Department of Women and Child Development was set up under the newly created Ministry of Human Resource Development.

1986

1987 (1) New 20 – point programme was launched (2) Indian Standards institute (ISI) renamed: Bureau of Indian Standards (BIS) (3) A world-wide "safe motherhood" campaign was launched by World Bank. (4) National Diabetics Control Programme and National AIDS Control Programme (NACP) (5) The Factories (Amendment) Act 1987 operated – with provisions to protect employees exposed to hazardous processes.
1989 Blood Safety Programme was launched The ESI (Amendment) Act 1989 operated – Modifications in dependent, employer, family, factory and seasonal factory definitions and provisions in original Act.
1990 Control of Acute Respiratory Infection (ARI) Programme initiated as a pilot project in 14 districts.
1991 India stages the last decade Census of the Century
1992 (1) Eighth Five Year Plan (1992–97) was launched (2) Child Survival and Safe Motherhood Programme (CSP) was launched on 20th August (3) The Infant Milk substitute, Feeding Bottles and Infant Foods (Regulation of Production, Supply and Distribution) Act 1992 came into force.
1993 (1) Revised National Tuberculosis Programme with DOTS introduced at Pilot Project in the country (2) National Nutrition Policy 1993 formulated
1994 (1) Return of plague after 28 years of silence (2) The Panchayati Raj Act came into force with all States completing the process of legislation.
1995 (1) IND (India), a Mother and child Development Services (IMDD) (2) The legislation on Transplantation of Human Organs was enacted to regulate the removal, storage and transplantation of human organs for therapeutic purposes and for prevention of commercial dealings in human organs (3) Expert committee on malaria submitted its report and recommended guidelines for Malaria Action Plan
1996 (1) Pulse Polio Immunization, the largest single day public health event took place on 9th December 1995 and 20th January 1996. The second phase of PPI was conducted on 7th December 1996 and 18th January 1997. (2) Family planning programme made target-free from 1st April 1996 (3) Prenatal Diagnostic Technique (Regulation and Prevention of Misuse) Act 1994 came into force from January 1996 (4) Yaws eradication programme launched.
2006 (1) WHO releases new paediatric growth chart based on breast-fed children's (2) Ban on child labour as domestic servant (3) RRTC covers whole country since March 2006 (4) National Family Health Survey-3 conducted (5) Ministry of Women and Child Development carried out the Ministry of Human Resources and development (6) IMNCI was launched in 16 states.
2007 (1) 11th Five Year Plan launched (2) NACP III launched (3) Indian Public Health Standards for PHC and sub-centres formulated (4) Management and Welfare of Parents and Senior Citizens Bill 2007 passed.
2008 (1) Non-communicable Disease Programme as pilot project launched on 4th Jan.
2009 Panemic Influenza A (H1N1) 2009 outbreak, New ICDS Mothers and Child Protection Card came into use.
2010 ICDS announces nutritional requirements and recommended dietary allowances for Indians. (1) India stages second census of the century.
2013 National Health Mission launched, RMNCH+A launched.
2014 (1) India Newborn Action Plan launched on 27th March. (2) India declared polio free country (3) Mission Indradhanush launched on 25th December.
2015 NITI Aayog replaces Yojana Aayog on 1st January 2015.

References
Health has been declared a fundamental human right. This implies that the State has a responsibility for the health of its people. National governments all over the world are striving to expand and improve their health care services. The current criticism against health care services is that they are (a) predominantly urban-oriented (b) mostly curative in nature, and (c) accessible mainly to a small part of the population. The present concern in both developed and developing countries is not only to reach the whole population with adequate health care services, but also to secure an acceptable level of Health for All, through the application of primary health care programmes.

Concept of health care
Since health is influenced by a number of factors such as adequate food, housing, basic sanitation, healthy lifestyles, protection against environmental hazards and communicable diseases, the frontiers of health extend beyond the narrow limits of medical care. It is thus clear that “health care” implies more than “medical care”. It embraces a multitude of services provided to individuals or communities by agents of the health services or professions, for the purpose of promoting, maintaining, monitoring, or restoring health.

The term “medical care” is not synonymous with “health care”. It refers chiefly to those personal services that are provided directly by physicians or rendered as the result of physicians’ instructions. It ranges from domiciliary care to resident hospital care. Medical care is a subset of health care system.

Health care is a public right, and it is the responsibility of governments to provide this care to all people in equal measure. These principles have been enshrined in the constitutions of all countries in the world, and in India, health care is completely a governmental function.

Health system
Health services are designed to meet the health needs of the community through the use of available knowledge and resources. It is not possible to define a fixed role for health services when the socio-economic pattern of one country differs so much from another. The health services are delivered by the “health system”, which constitutes the management sector and involves organisational matters.

Two major themes have emerged in recent years in the delivery of health services: (a) First, that health services should be organised to meet the needs of entire populations and not merely selected groups. Health services should cover the full range of preventive, curative and rehabilitation services. Health services are now seen as part of the basic social services of a country; (b) Secondly, it is now fully realised that the best way to provide health care to the vast majority of underserved rural people and urban poor is to develop effective “primary health care” services supported by an appropriate referral system. The social policy throughout the world was to build up health systems based on primary health care, towards the policy objective of Health for All by 2000 A.D.

Community participation is now recognized as a major component in the approach to the whole system of health care – treatment, promotion and prevention. The stress is on the provision of these services to the people – representing a shift from medical care to health care and from urban population to rural population.

Levels of health care
It is customary to describe health care service at 3 levels, viz. primary, secondary and tertiary care levels. These levels represent different types of care involving varying degrees of complexity.

1. Primary care level
It is the first level of contact of individuals, the family and community with the national health system, where “primary health care” (“essential health care”) is provided. As a level of care, it is close to the people, where most of their health problems can be dealt with and resolved. It is at this level that health care will be most effective within the context of the area’s needs and limitations (3).

In the Indian context, primary health care is provided by the community, primary health centres and their subcentres through the agency of multipurpose health workers, village health guides and trained auxiliaries. Besides providing primary health care, the village “health teams” bridge the cultural and communication gap between the rural people and organised health sector. Since India opted for “Health for All” by 2000 AD, the primary health care system has been reorganized and strengthened to make the primary health care delivery system more effective.

2. Secondary care level
The next higher level of care is the secondary (intermediate) health care level. At this level more complex problems are dealt with. In India, this kind of care is generally provided in district hospitals and community health centres which also serve as the first referral level(4).
3. Tertiary care level

The tertiary level is a more specialized level than secondary care level and requires specific facilities and attention of highly-qualified health workers (5). This care is provided by the regional or central level institutions, e.g., Medical College Hospitals, All India Institutes, Regional Hospitals, Specialized Hospitals and other Apex Institutions.

A fundamental and necessary function of health care system is to provide a sound referral system. It must be a two-way exchange of information and returning patients to those who referred them for follow-up care (6). It will ensure continuity of care and inspire confidence of the consumer in the system. For a large majority of developing countries (including India) this aspect of the health system remains very weak.

Changing concepts

With political independence, there was a national commitment to improve health in developing countries. Against this background different approaches to providing health care came into existence. These are:

1. Comprehensive health care

The term "comprehensive health care" was first used by the Bhore Committee in 1946. By comprehensive services, the Bhore committee meant provision of integrated preventive, curative and promotional health services from "womb to tomb" to every individual residing in a defined geographic area. The Bhore Committee defined comprehensive health care as having the following criteria:

(a) provide adequate preventive, curative and promotional health services;
(b) be as close to the beneficiaries as possible;
(c) has the widest cooperation between the people, the service and the profession;
(d) is available to all irrespective of their ability to pay;
(e) look after specifically the vulnerable and weaker sections of the community; and
(f) create and maintain a healthy environment both in homes as well as working places.

The Bhore Committee suggested that comprehensive health care should replace the policy of providing more medical care. This concept formed the basis of national health planning in India and led to the establishment of a network of primary health centres and subcentres.

The Government of India, during the successive 5-year plans has built up a vast infrastructure of rural health services based on primary health centres and subcentres. However, experience during the past 50 years has indicated that the primary health centres were not able to effectively cover the whole population under their jurisdiction, and their sphere of service did not extend beyond a 2-5 km radius. These facilities often did not enjoy the confidence of the people because they were understaffed and poorly supplied with medicines and equipment; as a result, there was growing dissatisfaction with the delivery of health services.

2. Basic health services

In 1965, the term "basic health services" was used by UNICEF/WHO in their joint health policy (7). They defined the term as follows: "A basic health service is understood to be a network of coordinated, peripheral and intermediate health units capable of performing effectively a selected group of functions essential to the health of an area and assuring the availability of competent professional and auxiliary personnel to perform these functions."

The change in terminology from comprehensive to basic health services did not affect materially the quality or content of health services. The manpower or drawbacks of the basic health services are those shared by the comprehensive health care services, viz., lack of community participation, lack of intersectoral coordination and dissociation from the socio-economic aspects of health.

3. Primary health care

A new approach to health care came into existence in 1978, following an international conference at Alma-Ata (USSR). This is known as "primary health care". It has all the hallmarks of a primary health care delivery, first proposed by the Bhore Committee in 1946 and now espoused worldwide by international agencies and national governments (8).

Before Alma-Ata, primary health care was regarded as synonymous with "basic health services", "first contact care", "easily accessible care", "services provided by generalists", etc. The Alma-Ata International conference gave primary health care a wider meaning. The Alma-Ata Conference defined primary health care as follows (9):

"Primary health care is essential health care made universally accessible to individuals and acceptable to them, through their full participation and at a cost the community and country can afford."

The primary health care is equally valid for all countries from the most to the least developed, although it takes varying forms in each of them. The concept of primary health care has been accepted by all countries as the key to the attainment of Health for All by 2000 AD. It has also been accepted as an integral part of the country's health system.

Elements of primary health care

Although specific services provided will vary in different countries and communities, the Alma-Ata Declaration has outlined 8 essential components of primary health care (9):

1. education concerning prevailing health problems and the methods of preventing and controlling them;
2. promotion of food supply and proper nutrition;
3. an adequate supply of safe water and basic sanitation;
4. maternal and child health care, including family planning;
5. immunization against major infectious diseases;
6. prevention and control of locally endemic diseases;
7. appropriate treatment of common diseases and injuries; and
8. provision of essential drugs.

Principles of primary health care

1. Equitable distribution

The first key principle in the primary health care strategy is equity or equitable distribution of health services, i.e., health services must be shared equally by all people, irrespective of their ability to pay, and all (rich or poor, urban or rural) must have access to health services. At
present, health services are mainly concentrated in the major towns and cities resulting in inequality of care to the people in rural areas. The worst hit are the needy and vulnerable groups of the population in rural areas and urban slums. This has been termed as social injustice. The failure to reach the majority of the people is usually due to inaccessibility. Primary health care aims to redress this imbalance by shifting the centre of gravity of the health care system from facilities (where three-quarters of the health budget is spent) to the rural areas (where three-quarters of the people live), and bring these services as near people's homes as possible.

2. Community participation

Notwithstanding the overall responsibility of the Central and State Governments, the involvement of individuals, families, and communities in promotion of their own health and safety to be an essential ingredient of primary health care. Countries are now conscious of the fact that universal coverage by primary health care cannot be achieved without the involvement of the local community. There must be a continuing effort to secure meaningful involvement of the community in the planning, implementation and maintenance of health services, besides maintaining reliance on local resources such as manpower, money and materials. In short, primary health care must be built on the principle of community participation (or involvement).

One approach that has been tried successfully in India is the use of village health guides and trained dai's. They are selected by the local community and trained locally in the delivery of primary health care to the community they belong, free of charge. By overcoming cultural and communication barriers, they provide primary health care in ways that are meaningful to the community. They are now considered that "health guides" and trained dai's are an essential feature of primary health care in India. These concepts are by no means new, they have been greatly influenced by experience in China where community participation in the form of bare-foot doctors took place on an unprecedented scale.

3. Intersectoral coordination

There is an increasing realization of the fact that the components of primary health care cannot be provided by the health sector alone. The Declaration of Alma-Ata states that "primary health care involves in addition to the health sector, all related sectors and aspects of national and community development, in particular agriculture, animal husbandry, transport, housing, power and works, communication and other sectors" (9). To achieve such cooperation, countries may have to review their administrative system, reallocate their resources and introduce suitable legislation to ensure that coordination can take place. This requires strong political will to translate values into action. An important element of intersectoral approach is planning — planning with other sectors to avoid unnecessary duplication of activities.

4. Appropriate technology

Appropriate technology has been defined as "technology that is scientifically sound, adaptable to local needs, and acceptable to those who apply it and those for whom it is used, and that can be maintained by the people themselves in keeping with the principle of self-reliance with the resources the community and country can afford" (10). The term "appropriate" is emphasized because it is some countries, large, luxurious hospitals that are totally inappropriate to the local needs, are built, which absorb a major part of the national health budget, effectively blocking any improvement in general health services. The same applies to using costly equipment, procedures and techniques whose cheaper, scientifically valid and acceptable ones are available, viz. oral rehydration fluid, standpipes which are socially acceptable, and financially more feasible than house-to-house connections, etc.

It will be seen from the above discussion that primary care is qualitatively a different approach to deal with the health problems of a community. Unlike the previous approaches (e.g. basic health services, integrated health care, vertical health services) which depended upon taking health services to the doors of the people, primary health care approach starts with the people themselves. This approach signifies a new dynamism in health care and has been described as Health by the people, placing people's health is people's hands (11). The end of the primary health care approach are the same as those of earlier approaches (i.e., attainment of an acceptable level of health by every individual), but the means adopted are different (12), that is, more equitable distribution and nation-wide coverage, more intersectoral coordination and more community involvement in health related matters. In short, primary health care goes beyond the conventional health services. It forms part of the larger concept of Human Resources and Development.

HEALTH FOR ALL

In 1977, it was decided in the World Health Assembly to lay down a Joint Declaration of Alma-Ata (20Wk). The fundamental principle of HFA strategy is equity, that is, an equal health status for people and countries, ensured by an equitable distribution of health resources. The Member countries of WHO at the 30th World Health Assembly defined Health for All as:

"attainment of a level of health that will enable every individual to lead a socially and economically productive life."

In 1978, the Alma-Ata International conference on Primary Health Care reaffirmed Health for All as the major social goal of governments, and stated that the best approach to achieve the goal of HFA is by providing primary health care, especially to the vast majority of underserved rural people and urban poor. It was envisaged that by the year 2000, at least essential health care should be accessible to all individuals and families in an acceptable and affordable way, with their full participation.

The Alma-Ata Conference called on all governments to formulate national policies, strategies and plans of action to launch and sustain primary health care as part of a national health system. It is left to each country to develop its norms and indicators for providing primary health care according to its own circumstances.

In 1981, a global strategy for HFA was evolved by WHO (13). The global strategy provides a global framework that is broad enough to apply to all Member States and flexible enough to be adapted to national and regional variations of conditions and requirements. This was followed by individual countries developing their own strategies for achieving HFA, and synthesis of national strategies for developing regional strategies.

The WHO has established 12 global indicators (13) as the
National strategy for HFA/2000

As a signatory to the Alma-Ata Declaration in 1978, the Government of India was committed to taking steps to provide HFA to its citizens by 2000 AD. In pursuance of this objective various attempts were made to evolve suitable strategies and approaches. In this connection two important reports appeared: (i) Report of the Study Group on “Health for All - an alternative strategy”, sponsored by ICSRR and ICMR, and (ii) Report of the Working Group on “Health for All by 2000 AD” sponsored by the Ministry of Health and Family Welfare, Government of India in 1983 (16) which committed the Government and people of India to the achievement of HFA.

The National Health Policy echoes the WHO call for HFA and the Alma-Ata Declaration. It laid down specific goals in respect of the various health indicators by different dates such as 1990 and 2000 AD. Foremost among the goals to be achieved by 2000 AD were:

1. Reduction of infant mortality from the level of 125 (1978) to below 60.
2. To raise the expectation of life at birth from the level of 52 years to 64.
3. To reduce the crude death rate from the level of 14 per 1000 population to 9 per 1000.
4. To reduce the crude birth rate from the level of 33 per 1000 population to 21.
5. To achieve a net reproduction rate of one.
6. To provide portable water to the entire rural population.

THE MILLENNIUM DEVELOPMENT GOALS

During September 2000, representatives from 189 countries met at the Millennium Summit in New York, to adopt the United Nations Millennium Declaration. The goals in the area of development and poverty eradication are now widely referred to as “Millennium Development Goals” (MDGs). The MDGs place health at the heart of development and represent commitments by governments throughout the world to do more to reduce poverty and hunger and to tackle ill-health, gender inequality, lack of education, access to clean water and environmental degradation. They are an integral part of the road map towards the implementation of the UN Millennium Declaration. Three of the 8 goals, 8 of the 18 targets required to achieve them, and 1b of the 48 indicators of progress, are health related. They assist in the development of national policies focusing on poor, and help track the performance of health programmes and systems. Although, the MDGs do not cover the whole range of public health domains, a broad interpretation of the goals provides an opportunity to tackle important cross-cutting issues and key constraints to health and development. Governments have set a date of 2015 by which they would meet the MDGs, i.e.

eradicate extreme poverty and hunger; achieve universal primary education; promote gender equality; improve maternal health; combat HIV/AIDS, malaria and other communicable diseases; ensure environmental sustainability; and develop a global partnership for development (17,18,19).

More recently one of the major changes made to the MDG configuration is the inclusion of a specific target on reproductive health: Millennium Development Goal 5, Target B, which seeks to “Achieve, by 2015, universal access to reproductive health.” This new target falls within the goal’s overarching objective of improving maternal health and complements its original target and associated indicators.

CONCEPTS AND DEFINITIONS OF MDG INDICATORS (20)

The concepts and definitions of MDGs are as follows (G.T. and I written in parenthesis are pertaining to goal number, target no and indicator no. of UN Declaration) (20):

Prevalence of underweight children (under five years of age) (G1.T2.14): Proportion of children under five years of age with low weight-for-age, as measured by percentage of children in moderate and severe undernutrition—those falling below 80% of the median weight for reference value or below 2 standard deviations of national or international reference populations, such as growth charts of the US National Center for Health Statistics.

Proportion (%) of population below minimum level of dietary energy consumption (G1.T2.15): Since there is no specific data available, proxy indicator “Proportion of population undernourished” is used. It is the proportion in percentage of persons whose food intake falls below the minimum requirement or food intake that is insufficient to meet dietary energy requirements continuously.

Under-five mortality rate (G4.T5.113): Probability of dying between birth and exactly five years of age, expressed per 1,000 live births.

Infant mortality rate (G4.T5.114): Probability of dying between birth and exactly one year of age expressed per 1,000 live births.

Proportion (%) of 1 year old children immunized for measles (G4.T9.115): The percentage of infants reaching their first birthday fully immunized against measles (1 dose).

Maternal mortality ratio (G5.T4.116): Annual number of maternal deaths per 100,000 live-births. A maternal death is the death of a woman while pregnant or within 42 days of termination of pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes.

Proportion (%) of births attended by skilled health personnel (G5.T6.117): The proportion in percentage of births attended by skilled personnel per 100 live-births. Skilled health personnel refer exclusively to those health personnel (for example, doctors, nurses, midwives) who have been trained to proficiency in the skills necessary to manage normal deliveries and diagnose or refer obstetric complications. Traditional birth attendants trained or untrained, are not included in this category.

HIV prevalence among young people (G6.T7.118): Since the relevant data is not available, the proxy indicator as proposed by UNAIDS/WHO is used. The proxy indicator is
"HIV prevalence among 15–24 years old by sex" which is the estimated number of young people (15–24 years old) living with HIV as per proportion of the same population and sex. These country-specific estimates are expressed as a range generated by regional modelling. The other proportion indicator is "HIV prevalence rate among population 15–49 years of age".

Condom use in high-risk population (G6.T7.119): Since the data is not available, it has been proposed to use "condom-use among 15–24 years old by sex". This is the percentage of young men and women of age 15–24 years, who said that they used a condom the last time they had sex with a non-marital, non-cohabiting partner of those who have had sex with such a partner in the last 12 months.

Ratio of children orphaned/non-orphaned in schools (G6.T7.120): Since the data is not available, the proxy indicator "AIDS orphans currently living" which is the estimated number of children (0–14) in a given year, having lost their mother or both parents to AIDS.

Malaria death rate per 100,000 in children (0–4 years of age) (G6.T8.121): Proportion of children (0–4 years of age) died due to malaria in a given year.

Malaria prevalence rate per 100,000 population (G6.T8.121): Proportion of notified or reported cases of malaria per 100,000 population in a given year. It is malaria crude death rate.

Proportion (%) of population under-age 5 in malaria risk areas using insecticide treated bed nets (G6.T8.122): The percentage of children under-five years of age who are using insecticide treated bed nets among the same population living in malaria risk area, in a given year.

Proportion (%) of population under-age 5 with fever being treated with anti-malarial drugs (G6.T8.122): The percentage of children under-five years of age who are with fever being treated with anti-malarial drugs among the same population living in malaria risk area, in a given year.

Tuberculosis death rate per 100,000 (G6.T8.123): Proportion of people of all age groups died due to tuberculosis in a given year.

Tuberculosis prevalence rate per 100,000 (G6.T8.123): Proportion of tuberculosis cases of all age groups per 100,000 population in a given year.

Proportion (%) of smear-positive pulmonary tuberculosis cases detected and put under directly observed treatment short-course (DOTS) (G6.T8.124): Since the base line data is not available WHO proposed to use "DOTS detection rate".

Proportion (%) of smear-positive pulmonary tuberculosis cases detected cured under directly observed treatment short course (DOTS) (G6.T8.124): Since the baseline data is not available WHO proposed to use "DOTS cure rate" which implies treatment success rate that is treatment completion rate and cure rate.

Proportion (%) of population using biomass fuel (G7.T7.129): Biomass fuel is any material, derived from plants or animals, deliberately burnt by human, for example, wood, animal dung, crop residues and coal. Since the baseline data is not available the proxy indicator is proposed as "percentage of populations using solid fuels".

Proportion (%) of population with sustainable access to an improved water source, rural (G7.T10.130): Since the baseline data is not available, the proxy indicator "percentage of population with access to improved drinking water sources, rural" is used. "Improved" water sources means household connection, public standpipes, borehole, protected dug well, protected spring, rainwater collection. "Access" means the availability of at least 20 litres water per person per day from a source within one kilometre of the user's dwelling.

Proportion (%) of population with sustainable access to an improved water source, urban (G7.T10.130): Since the baseline data is not available, the proxy indicator "percentage of population with access to improved drinking water sources, urban" is used. "Improved" water sources mean household connection, public standpipes, borehole, protected dug well, protected spring, rainwater collection. "Access" means the availability of at least 20 litres water per person per day from a source within one kilometre of the user's dwelling.

Proportion (%) of urban population with access to improved sanitation (G7.T11.131): "Improved" sanitation means: connection to a public sewer, connection to septic system, pour-flush latrine, simple pit latrine, or ventilated improved pit latrine. The excrete disposal system is considered adequate if it is private or shared (but not public), and if hygienically, separates human excreta from human contact.

Proportion (%) of population with access to affordable drugs on a sustainable basis (G8.T7.146): Since the baseline data is not available, the proxy indicator "percentage of population with access to essential drugs", which WHO routinely reports for international comparison, is used. Every year, in order to estimate the level of access to essential drugs, WHO Global Action Programme on Essential Drugs interviews relevant experts in each country about the pharmaceutical situation. The interviewees could choose from four levels of access by the population to essential drugs: less than 50%; between 50–80%; 80–95% and above 95%. They indicate which category is most appropriate for their country. Essential drugs are those drugs that satisfy the health care needs of the majority of the population.

The indicators selected to monitor progress towards MDG, 5 Target B are as follows:

- Condom prevalence rate: Percentage of women aged 15–49 in union currently using contraception.
- Adolescent birth rate: Annual number of births to women aged 15–19 per 1,000 women in that age group. Alternatively, it is referred to as the age-specific fertility rate for women aged 15–18.
- Antenatal care coverage: Percentage of women aged 15–49 attended at least once during pregnancy by skilled health personnel (doctors, nurses or midwives) and the percentage attended by any provider at least four times.

Urns need for family planning: Refers to women who are fecund and sexually active but are not using any method of contraception and report not wanting any more children or wanting to delay the birth of the next child.

Table 1 shows the detailed information regarding the indicators of health related MDGs in India, i.e. the baseline (1990) and current level data (2010).

**Health Care Delivery**

The challenge that exists today in many countries is to reach the whole population with adequate health care services and to ensure their utilization. The "large hospital" which was chosen hitherto for the delivery of health services has failed in the sense that it serves only a small part of the population, that too, living within a small radius of the building and the services rendered are mostly curative in nature. Therefore, it has been aptly said that these large hospitals are more ivory towers of diseases than centres for the delivery of comprehensive health care services. Rising costs in the maintenance of these large hospitals and their failure to meet the total health needs of the community have led many countries to seek 'alternative' models of health care at the level of the primary health care services that are reasonably inexpensive, and have the basic essentials required by rural population.

**The Model**

A number of models have been developed for the delivery of health care services (22). One of the simplest models is shown in Table 2.

</table>

**Strenghts:** Dept. of PW/DGI is covering free supply of essential drugs to sub-centres, primary health centres and community health centres. It was considered appropriate that Dept. of Family Welfare may cover the indicator while also taking into account the free drugs supplied under other National Health Programmes like NLUP, RNTCP and VBCDP through Govt. health facilities. **(21)**
In actual practice the model is more detailed and complex. The INPUTS are the health status or health problems of the community; they represent the health needs and health demands of the community. Since resources are always limited to meet the many health needs, priorities have to be set. This envisages proper planning so that resources are not wasted. An account of the health planning has already been given in the preceding chapter. The HEALTH CARE SERVICES are designed to meet the health needs of the community through the use of available knowledge and resources. The services provided should be comprehensive and community-based. The resources must be distributed according to the needs of the community. The HEALTH CARE SYSTEM is intended to deliver the health care services; in other words, it constitutes the management sector, and involves organizational matters. The final outcome or the OUTPUT is the changed health status or improved health status of the community which is expressed in terms of lives saved, deaths averted, diseases prevented, cases treated, expectation of life prolonged, etc. Models such as these are being employed for improving health care services. A discussion of the application of the model (Fig. 1) in the Indian context is given in the following pages.

HEALTH STATUS AND HEALTH PROBLEMS

An assessment of the health status and health problems is the first requisite for any planned effort to develop health care services. This is also known as Community Diagnosis. The data required for analyzing the health situation and for defining the health problems comprise the following:

2. Demographic conditions of the population.
3. Environmental conditions which have a bearing on health.
4. Socio-economic factors which have a direct effect on health.
5. Cultural background, attitudes, beliefs, and practices which affect health.
6. Medical and health services available.
7. Other services available.

An analysis of the health situation in the light of the above data will bring out the health problems and health needs of the community. These problems are then ranked according to priority or urgency for allocation of resources. A brief description of current demographic and mortality profile and the health problems of India is given in the following pages.

1. Demographic profile

A major concern today is population explosion. The demographic profile is characterised by:

- a. large population base
- b. high fertility rates in terms of birth rate and family size
- c. low or declining mortality
- d. "young" population (about 35.35 per cent of the population) is below the age of 15 years
- e. the proportion of literate population is close to 34.62 per cent: this explains why the decline in birth rate has been so slow
- f. dependency ratio of £2 per 100; that is, every economically productive member has to support almost one dependant

Table 3 summarizes the most recent demographic information available.

![FIG. 1](Model of health care system)
2. Mortality profile

During the last few decades, there has been a notable improvement in the health status of the population. The death rate has steadily declined from 21 (1965) to 7.0 (2012). The life expectancy at birth has gone up considerably since 1951, recording an estimated 66 years during 2012. The mortality rates for a number of infectious and communicable diseases have also registered a decline (e.g., cholera, tuberculosis, malaria).

However, a deeper study reveals distressing situation. India's health standards are still low compared to those in developed countries. While in the world as a whole, the IMR for the year 2012 is about 35 per 1000 live births, and in the developed countries as low as 5, in India it is as high as 42. Our life expectancy of about 66 years lags behind by almost 12-15 years compared to that in developed countries where it is currently between 71 and 80 years.

The mortality profile in terms of age-sex and urban-rural distribution is presented in Table 4 and 5. It shows wide variations in crude death rate between rural and urban areas. The current urban death rate (2012) was 5.6 and the rural death rate 7.6 per 1000 of population. There were also considerable interstate variations in death rate, as for example, during 2012 the death rate in Odisha was highest at 8.5 compared to the national average of 7.0 and 4.2 in Delhi. Among the states, Kerala had the lowest IMR of 12 per 1000 live births and Madhya Pradesh had the highest IMR of 56 per 1000 live births (24).

Table 4 shows that the death rate is the highest in the age group 0-4 years. This is as a result of malnutrition and infection. 15 to 25 per cent of total deaths are attributed to infectious and parasitic diseases.

Health problems

The HEALTH PROBLEMS of India may be conveniently grouped under the following heads:

1. Communicable disease problems
2. Non-communicable disease problems
3. Nutritional problems
4. Environmental sanitation problems
5. Medical care problems
6. Population problems

1. Communicable disease problems

Communicable diseases continue to be a major problem in India. Diseases considered to be of great importance today are:

- Malaria: Malaria continues to be a major health problem in India. Although total malaria cases have declined compared to previous years, the proportion of P. falciparum has increased. Malaria cases have increased in

All ages (Crude death rate) 7.0 | 7.7 | 6.4 | 7.0

Source: (23)
North-East states, Madhya Pradesh, Chhattisgarh, Jharkhand, Orissa, Andhra Pradesh, Maharashtra etc. During 2013 there were 0.26 million cases of malaria (which included 0.44 million cases of P. falciparum) and 379 deaths.

(b) Tuberculosis: Tuberculosis remains a public health problem, in India accounting for one-fifth of the world incidence. Every year about 2.6 million people develop tuberculosis, of which about 0.62 million are new smear positive cases and about 0.24 million people die of TB every year. The emergence of HIV-TB co-infection and multidrug-resistant TB has increased the severity and magnitude of the disease. In March 2006 RNTCP has achieved national-wide coverage. (c) Diarrhoeal diseases: Diarrhoeal diseases constitute one of the major causes of morbidity and mortality, specifically in children below 5 years of age. They are responsible for about 10.76 million cases of diarrhoea each year. Outbreaks of diarrhoeal diseases (including cholera) continue to occur in India due to poor environmental conditions.

(d) ARI: Acute respiratory infections are one of the major causes of mortality and morbidity in children below 5 years of age. During 2013, 31.7 million episodes of ARI were reported in 3.278 deaths. (e) Leprosy: Leprosy is another important public health problem in India. During the year 2013–2014, total of 1.27 lakh new cases were detected, out of which child cases were 9.49% and deformity grade II and above was 4.14%. 51.46% of these cases are estimated to be multibacillary. All the Stater and Union Territories report cases of leprosy. However, there are considerable variations not only between one State and another, but also between one district and another. With the progress of DOTS programme, India has achieved the goal of leprosy elimination at national level. (f) Filariasis: The problem of filariasis remains considerable in many parts of the country. The population at risk is over 600 million. To achieve elimination of LF, the Govt. of India has launched nationwide Annual MDA campaign. (g) Malaria: Malaria population of India has increased from 90 million in 2000 to 206 million in 2012, according to WHO estimates. The population at risk is over 600 million. To achieve elimination of LF, the Govt. of India has launched nationwide Annual MDA campaign. (h) tuberculosis: Tuberculosis remains a public health problem in India. The population at risk is over 600 million. To achieve elimination of LF, the Govt. of India has launched nationwide Annual MDA campaign. (i) Cholera: Cholera is a major public health problem in India. The population at risk is over 600 million. To achieve elimination of LF, the Govt. of India has launched nationwide Annual MDA campaign.

3. Nutritional problems

From the nutritional point of view, the Indian society is a dual society, consisting of a small group of well fed and a very large group of undernourished. The high income groups are showing diseases of affluence which one finds in developed countries.

The specific nutritional problems in the country are:
(a) Protein-energy malnutrition: Insufficiency of food— the so-called “food gap”—appears to be the chief cause of PEM, which is a major health problem, particularly in the first years of life. The great majority of cases of PEM, nearly 80 per cent are mild and moderate cases. The incidence of severe cases is 1 to 2 per cent in preschool age children. The problem exists in all the States and the nutritional marasmus is more frequent than kwashiorkor.
(b) Nutritional anaemia: India has probably the highest prevalence of nutritional anaemia in women and children. About one-half of non-pregnant women and young children are estimated to suffer from anaemia. 60 to 80 per cent of pregnant women are anaemic. 19 per cent of maternal deaths are attributed to anaemia. According to NFHS-3, about 57.9 per cent women are anaemic of which 54.6 per cent are in urban areas and 59 per cent in rural areas. The survey also shows that the incidence of anaemia in children aged 0-35 months is 70.2 per cent with 72.7 per cent in urban areas and 81.2 per cent in rural areas. By far the most frequent cause of anaemia is iron deficiency, and less frequently folate and vitamin B12 deficiency. (c) Low birth weight: This is a major public health problem in many developing countries. About 28 per cent of low birth weight babies (less than 2.5 kg), as compared to about 4 per cent in some developed countries. Maternal malnutrition and anaemia are mainly responsible for this condition. (d) Xerophthalmia (nutritional blindness): About 0.04 per cent of total blindness in India is attributed to nutritional deficiency of vitamin A. Keratomalacia has been the major cause of nutritional blindness in children usually between 1-3 years of age. Subclinical deficiency of vitamin A is also widespread and is associated with increased morbidity and mortality from respiratory and gastro-intestinal infections. (e) Edema deficiency disorders: Goiters and other iodine deficiency disorders (IDD) have been known to be highly endemic in sub-Himalayan regions. Reassessment of the magnitude of the problem by the Indian Council of Medical Research showed that the problem is not restricted to the “goitre belt” as was thought earlier, but is extremely prevalent in other parts of India as well. It has been found that out of 924 districts surveyed in 29 states and at UTs, 263 districts...
are endemic i.e. where the prevalence of IOD is more than 10 per cent. It is also estimated that more than 71 million people are suffering from goitre and other IODs. (27) Other nutritional problems of importance are limnitis and endemic fluorosis in certain parts of the country. To these must be added the widespread adulteration of foodstuffs.

4. Environmental sanitation

The most difficult problem to tackle in this country is perhaps the environmental sanitation problem, which is multifaceted and multifactorial. The great sanitary awakening which took place in England in 1840's is yet to be born. The twin problems of environmental sanitation are lack of safe water in many areas of the country and primitive methods of excreta disposal. Besides these, there has been a growing concern about the impact of "new" problems resulting from population explosion, urbanization and industrialization leading to hazards to human health in the air, in water and in the food chain. At the United Nations Water Conference in Argentina, in 1977, it was recommended that the priority should be given to the provision of safe water supply and sanitation services for all. As of year 2012 safe water is available to 96 per cent of the urban and 87 per cent of the rural population; and adequate facilities for waste disposal to 54 per cent of the urban and 21 per cent of the rural population. The problem is gigantic.

5. Medical care problems

India has a national health policy. It does not have a national health service. The financial resources are considered inadequate to furnish the costs of running such a service. The existing hospital-based, disease-oriented health care delivery system is unable to provide health benefits mainly to the urban elite. Approximately 80 per cent of health facilities are concentrated in urban areas. Even in urban areas, there is an uneven distribution of doctors. With large migrations occurring from rural to urban areas, urban health problems have been aggravated and include overcrowding in hospitals, inadequate staffing and scarcity of certain essential drugs and medicines. The rural areas where nearly 72 per cent of the population live, do not enjoy the benefits of the modern curative and preventive health care. Many villages rely on indigenous systems of medicine. Thus the major medical care problem in India is inequitable distribution of available health resources between urban and rural areas, and lack of penetration of health services to the social periphery. The HPK/2000 movement and the primary health care movement which gave stress on equity, intersectional coordination and community participation seek to redress these imbalances.

6. Population problem

The population problem is one of the biggest problems facing the country, with its inevitable consequences on all aspects of development, especially employment, education, housing, health care, sanitation and environment. The country's population has already reached one billion mark by the turn of the century.

The Government has set a goal of 1 per cent population growth rate by the year 2000 (which was not attained); currently, the country's growth rate is 1.8 per cent. This calls for the "two child family norm". The population size and structure represent the most important single factor in health and manpower planning in India today where the law of diminishing returns, among other factors, plays an important role in the economic development of the country.

RESOURCES

Resources are needed to meet the vast health needs of a community. No nation, however rich, has enough resources to meet all the need for all health care. Therefore an assessment of the available resources, their proper allocation and efficient utilization are important considerations for providing efficient health care services. The basic resources for providing health care are:

(i) Health manpower
(ii) Money and material;
(iii) Time

Health manpower

The term "health manpower" includes both professional and auxiliary health personnel who are needed to provide the health care. An auxiliary is defined by WHO as "technical worker in a certain field with less than full professional training". Health manpower requirements of a country are based on (i) health needs and demands of the population; and (ii) desired outputs. The health needs in turn are based on the health situation and health problems and aspirations of the people.

Health manpower planning is an important aspect of community health planning. It is based on a series of accepted ratios such as doctor-population ratio, nurse-population ratio, bed-population ratio, etc. They are given in Table 6. The country is producing annually, on an average 31,296 allopathic doctors; 9,865 Ayurvedic graduates; 1,025 Unani graduates; 320 Siddha graduates and 12,785 Homeopathic graduates (26).

Although the a-avages are satisfactory on a national basis, they vary widely within the country. There is also maldistribution of health manpower between rural and urban areas. Studies in India have shown that there is a concentration of doctors (up to 73.6 per cent) in urban areas where only 26.4 per cent of population live. This maldistribution is attributed to absence of amenities in rural areas, lack of job satisfaction, professional isolation, lack of rural experience and inability to adjust to rural life.
The national averages of doctor-population ratio, population-bed ratio and nurse to doctor ratio in some countries are shown in Table 7.

Health manpower requirements are subject to change, both qualitatively and quantitatively, as new programmes, projects and philosophies are introduced into the health care system. For example, there has been a change from unipurpose to multipurpose strategy. Then came the goal of Health for All. In addition, national health programmes such as tuberculosis control, leprosy eradication and control of blindness needed more trained workers and technicians. Thus during the past decade many new categories of health manpower have been introduced. They include village health guides, multipurpose workers, technicians, ophthalmic assistants, etc. Table 8 gives the total health manpower current stock under the “rural health scheme”.

Money and material

Money is an important resource for providing health services. Scarcity of money affects all parts of the health delivery system. In most developed countries, average government expenditure for health is about 18 per cent of GNP. In developing countries it is less than 1 per cent of the GNP and it seldom exceeds 2 per cent of the GNP. This translates into an average of a few dollars per person per year in the underdeveloped countries as compared to several hundred dollars in developed ones. To make matters worse, much of the spending is for services that reach only a small fraction of the population.

To achieve Health for All, WHO has set as a goal the expenditure of 5 per cent of each country’s GNP on health care. At present India is spending about 3 per cent of GNP on health and far behind developed countries.

Since money and material are always scarce resources, they must be put to the most effective use, with an eye on maximising output of results for investment. Since deaths from preventable diseases such as whooping cough, measles, tuberculosis, tetanus, diphtheria, malnutrition frequently occur in developing countries, the case is strong for investing resources on preventing these diseases rather than spending money on multiplying prestigious medical institutions and other establishments which absorb a large portion of the national health budget (30). Management techniques such as cost-effectiveness and cost-benefit analysis are now being used for allocation of resources in the field of community health.

Time

“Time is money”, someone said. It is an important dimension of health care services. Administrative delays in sanctioning health project imply loss of time. Proper use of man-hours is also an important time factor. For example, a survey by WHO has shown that an Auxiliary Nurse Midwife spends 45 per cent of her time in giving medical care, 40 per cent in travelling, 5 per cent on paper work; and only 10 per cent in performing duties for which she has been trained (31). Such studies may be extended to other categories of health personnel with a view to promote better utilisation of the time resource.

To summarise, resources are needed to meet the many health needs of a community. Resources are desperately short in the health sector in all poor countries. What is important is to employ suitable strategies to get the best out of limited resources.

Health care services

The purpose of health care services is to improve the health status of the population. The goals to be achieved have been fixed in terms of mortality and morbidity reduction, increase in expectation of life, decrease in population growth rate, improvements in nutritional status, provision of basic sanitation, health manpower requirements and resources development and certain other parameters such as food production, literacy rate, reduced levels of poverty, etc.

The scope of health services varies widely from country to country and influenced by general and ever changing national, state and local health problems, needs and attitudes as well as the available resources to provide these services. A comprehensive list of health services may be found in the Report of the WHO Expert Committee (1961) on “Planning of Public Health Services” (32).

There is now broad agreement that health services should be (a) comprehensive (b) accessible (c) acceptable (d) provide scope for community participation, and (e) available at a cost the community and country can afford. These are the essential ingredients of primary health care which forms an integral part of the country’s health system, of which it is the central function and main agent for delivering health care (9).

Health care systems

The health care system is intended to deliver the health care services. It constitutes the management sector and involves organisational matters. It operates in the context of
1. Village level

One of the basic tenets of primary health care is universal coverage and equitable distribution of health resources. That is, health care must penetrate to the farthest reaches of rural areas, and that everyone should have access to it. To implement this policy at the village level, the following schemes are in operation:

a. Village Health Guides Scheme
b. Training of Local Dais
c. ICDS Scheme
d. ASHA Scheme

A Village Health Guide is a person with an aptitude for social service and is not a full time government functionary. The Village Health Guides Scheme was introduced on 2nd October 1977 with the idea of securing people's partial completion of their own health. The scheme was launched in all States except Kerala, Karnataka, Tamil Nadu, Anurachh Prades and Jammu and Kashmir which had alternative systems (e.g., Mini-health Centres in Tamil Nadu) of providing health services at the village level.

The Health Guides are now mostly women. A circular was issued by Government of India in May 1986 that male Health Guides would be replaced by female Health Guides (33). The Health Guides come from and are chosen by the community in which they work. They serve as links between the community and the governmental infrastructure. They provide the first contact between the individual and the health system. The guidelines for their selection are (34):

(a) they should be permanent residents of the local community, preferably women
(b) they should be able to read and write, having minimum formal education at least up to the VI standard
(c) they should be acceptable to all sections of the community
(d) they should be able to spare at least 2 to 3 hours every day for community health work.

After selection, the Health Guides undergo a short training in primary health care. The training is arranged in the nearest primary health centre, subcentre or any other suitable place for the duration of 200 hours, spread over a period of 3 months. During the training period they receive a stipend of Rs. 200 per month.

On completion of training, they receive a working manual and a kit of simple medicines belonging to the modern and traditional systems of medicine in vogue in that part of the country to which they belong. Broadly the duties assigned to health guides include treatment of simple ailments and activities in aid of first aid, mother and child health including family planning, health education and sanitation. The manual or guide-book gives them detailed information about medical care of common illnesses – of what they can and cannot do. In practical terms, they know exactly what should be done when confronted with a situation, when they can begin treatment by themselves and when they should refer the patient immediately to the nearest health centre.

The Health Guides are free to attend to their normal vocation. They are expected to do community health work in their spare time of about 2 to 3 hours daily for which they are paid an honorarium of Rs. 50 per month and drugs worth Rs. 600 per annum. As the training involves expenditure, the Government will not train another Health
HEALTH CARE SYSTEMS

Guide from the same village before three years. As of date, there are 3,253 with village Health Guides functioning in the county (45). The national target is to achieve one Health Guide for each village or 1,000 rural population.

b. Local dais (36)

Most deliveries in rural areas are still handled by untrained dais who are often the only people immediately available for consultation during the perinatal period. An extensive programme has been undertaken, under the Rural Health Scheme, to train all categories of local dais (traditional birth attendants) in the country to improve their knowledge in the elementary concepts of maternal and child health and sterilization, besides obstetric skills. The training is for 30 working days. Each dai is paid a stipend of Rs. 300 during her training period. Training is given at the PHC, subcentres or MCH centre for 2 days in a week, and on the remaining four days of the week they accompany the Health worker (Female) to the villages preferably in the dai's own area. During her training each dai is required to conduct at least 2 deliveries under the guidance and supervision of the HW (F), ANM or HA (F). The emphasis during the training is on asepsis so that home deliveries are conducted under safe hygienic conditions thereby reducing the maternal and infant mortalities.

After successful completion of training, each dai is provided with a delivery kit and a certificate. These dais are also expected to play a vital role in propagating small family norms since they are more acceptable to the community. The national target is to train one local dai in each village.

c. Anganwadi worker

Angan literally means a courtyard. Under the ICDS (Integrated Child Development Services) Scheme, there is an anganwadi worker for a population of 400-800. There are about 100 such workers in each ICDS Project. As of date over 6,719 such blocks are functioning in the country. The anganwadi worker is selected from the community she is expected to serve. She undergoes training in various aspects of health, nutrition, and child development for 4 months. She is a part-time worker and is paid an honorarium of Rs. 1500 per month for the services rendered, which include health check-up including maintenance of growth chart, immunization, supplementary nutrition, health education, non-formal pre-school education and referral services. The beneficiaries are especially nursing mothers, pregnant women, other women (15–45 years), children below the age of 6 years and adolescent girls (37). Along with Village Health Guides, the anganwadi workers are the community's primary link with the health services and all other services for young children.

d. ASHA

Please refer to page 409 for details.

2. Sub-centre level

The sub-centre is the peripheral outpost of the existing health delivery system in rural areas. They are being established on the basis of one sub-centre for every 5000 population in general and one for every 3000 population in hilly, tribal and backward areas. As of March 2014, 152,326 sub-centres were established in the country.

A sub-centre provides interface with the community at the grass-root level, providing all the primary health care services. Of particular importance are the packages of services such as immunization, antenatal and postnatal care, prevention of malnutrition and common childhood diseases, family planning, services and counselling. They also provide elementary drugs for minor ailments such as ARI, diarrhoea, fever, worms, infestation etc. The care provided mostly meets the health needs of the community. Besides the above, the government implements several national health and family welfare programmes through these frontline workers.

Currently, a sub-centre is staffed by one Female Health Worker known as Auxiliary Nurse Midwife (ANM) and one Male Health Worker known as Multipurpose Worker (Male). One Health Assistant (Female) known as Lady Health Visitor (LHV) and one Health Assistant (Male) located at the PHC level are entrusted with the task of supervision of all sub-centres under a PHC. The Ministry of Health and Family Welfare, Govt. of India provides assistance to all the sub-centres in the country since April 2002 in the form of salary of ANMs and LHVs, rent (if located in a rented building) and contingency, in addition to drugs and equipment kits. The salary of Male Health Workers is borne by the State Governments. In addition, a voluntary worker is provided at the sub-centre level as a helper to ANM, as and when needed. The ANM pays to the voluntary worker from her contingency fund.

Indian Public Health Standards for sub-centres (38)

In order to provide quality care in these sub-centres, Indian Public Health Standards (IPHS) are being prescribed to sub-centres to provide comprehensive primary health care services to the community and achieve and maintain an acceptable standard of quality of care. These standards would monitor and improve the functioning of the sub-centres. These services are called assured services and are as follows (38).

1. Maternal health care:

a) Antenatal care: (a) Early registration of pregnancy (ideally 12 weeks of pregnancy). Minimum three antenatal check-ups. Recording of general check-up, weight, blood pressure, abdominal examination, haemoglobin, routine urine examination and blood group (at first visit if not done previously); (b) Folic acid supplementation from first trimester and folic acid and iron supplementation from 12 weeks onwards; (c) Tetanus toxoid immunization; (d) Identification of high-risk pregnancy and referral; (e) Counselling on diet, pre-birth preparedness and rest.

b) Post-natal care: (a) Promotion of institutional deliveries; (b) Skilled attendance at home deliveries; and (c) Appropriate and prompt referral in case of complications.

2. Child health care: (a) Essential new born care as per guidelines; (b) Promotion of exclusive breast feeding for 6 months; (c) Full immunization of all infants and children against vaccine preventable diseases; (d) Vitamin A prophylaxis; and (e) Prevention and control of childhood diseases like malnutrition, ARI, diarrhoea etc.

3. Family Planning and Contraception: (a) Education, motivation and counselling to adopt appropriate family planning method; (b) Provision of contraceptives such as...
condoms, oral pills, emergency contraceptives and IUD insertion (wherever ANM is trained for IUD insertion); and (c) Follow up services to the eligible couples adopting permanent methods of tubectomy and vasectomy.

4. Counselling and appropriate referral for safe abortion service (MTP).

6. Assistance to school health services.

8. Promotion of sanitation including use of toilet and appropriate garbage disposal.

9. Field visits by appropriate health workers for disease surveillance, family welfare services including STI, RTI awareness.

11. Curative services for minor ailments including fever, diarrhoea, worm infestation and first-aid, appropriate and prompt referral if needed. To organize Health Day at anganwadi centres at least once in a month. To provide AYUSH treatment.

12. Training of Traditional Birth Attendants and ASHA/community health volunteers.

13. Co-ordinate services of anganwadi workers, ASHA, village health and sanitation committee etc.

National AIDS Control Programme (NACP): (a) IEC activities to enhance awareness and preventive measures about STIs and HIV/AIDS, PPTCT services and HIV/TB coordination; (b) counselling and referral of persons practicing high risk behaviour in relation to HIV/AIDS and STD; (c) linkage with microscopy centre for HIV/TB diagnosis; (d) condom promotion and distribution of condoms to the high risk groups; and (e) help and guide people with HIV/AIDS receiving ART with focus on adherence.

National Vector Borne Disease Control Programme (NVBDCP): Prevention of breeding places of vectors through IEC, community mobilization, collection of blood smears from all fever cases, supply of anti-malarial drugs and follow-up of patients on treatment are the activities that are required at the sub-centre level. Rapid test kits for malaria may be used in sub-centre wherever such provision has been made. Assistance to integrated vector control activities in relation to Malaria, Filaria, JE, Dengue, Kala- Azar etc. as prevalent in specific areas and record keeping and reporting of the same. Where filarial is endemic, identification of cases of lymphoedema / elephantiasis and hydrocele and their referrals to PHC/CHC for appropriate management. The disease specific guidelines issued by NVBDCP are to be followed.

National Leprosy Eradication Programme (NLEP): Refer the suspected cases of leprosy (patients with skin patches with loss of sensation) to PHC, provision of MDT to diagnosed patients of leprosy at sub-centre, follow-up and defaulter retrieval. Educating public about sign, symptoms and complication of leprosy and availability of MDT at government health institutions.

Integrated Disease Surveillance Projects (IDSP): (a) Surveillance about any abnormal increase in cases of diarrhoea/dysentery, fever with rigors, fever with rash, fever with jaundice or fever with unconsciousness and early reporting to concerned PHC; (b) Weekly reporting of information for syndromic surveillance in prescribed format to primary health centres on every Monday.

Revised National tuberculosis Control Programme (RNTCP): Referral of suspected symptomatic cases to the PHC/Microscopy centre; and provision of DOTS at sub-centre and proper documentation and follow-up.

National Blindness Control Programme (NBCP): IEC is the major activity to help identify cases of blindness and refer suspected cataract cases to the PHC/CHC.

Non-communicable Disease (NCD) and cancer control programmes: IEC to sensitize the community about prevention of cancers and other NCDs, early detection through awareness regarding warning signs and appropriate and prompt referral of suspect cases.

Promotion of medicinal herbs: Locally available medicinal herbs/plants should be grown around the sub-centre.

Record of vital events: Recording and reporting of vital events including births and deaths, particularly of mothers and infants to the health authorities; maintenance of all the relevant records concerning mother, child and eligible couples in the area.

Manpower requirement

In order to provide above services, each sub-centre should have the following personnel:

<table>
<thead>
<tr>
<th>Manpower</th>
<th>Existing</th>
<th>Proposed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Health worker (female)</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>Health worker (male)</td>
<td>1</td>
<td>1 (funded and appointment by the state government)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>(optional)</td>
</tr>
<tr>
<td>Total</td>
<td>2/3</td>
<td>3/4</td>
</tr>
</tbody>
</table>

* The voluntary worker at the sub-centre level should preferably be a Trained Birth Attendant (TBA) and be paid Rs. 200/- at least (with equal contribution by the Government of India and the concerned State).

3. Primary health centre level

The concept of primary health centre is not new to India. The Bhore committee in 1946 gave the concept of a primary health centre as a basic health unit, to provide, as close to the people as possible, an integrated curative and preventive health care to the rural population with emphasis on preventive and promotive aspects of health care. The Bhore Committee aimed at having a health centre to serve a population of 10,000 to 20,000 with 6 medical officers, 6 public health nurses and other supporting staff. But in view of the limited resources, the Bhore Committee’s recommendations could not be fully implemented, even after a lapse of 60 years.

The health planners in India have visualized the primary health centre and its sub-centres as the proper infrastructure to provide health services to the rural population. The Central Council of Health at its first meeting held in January 1953 had recommended the establishment of primary health centres in community development blocks to provide comprehensive health care to the rural population. The number of primary health centres established since then had increased from 76 in during the First Five Year Plan to 5484
by the end of the Fifth Plan (1975–1980) – each PHC covering a population of 100,000 or more spread over some 100 villages in each community development block. These centres were functioning as peripheral health service institutions with little or no community involvement. Increasingly, these centres came under criticism as they were not able to provide adequate health coverage, partly because they were poorly staffed and equipped, and partly because they had to cover a large population of one lakh or more. The Muddalir Committee in 1962 had recommended that the existing primary health centres should be strengthened and the population to be served by them be scaled down to 40,000.

The Declaration of Aina-Ata Conference in 1978 setting the goal of Health for All by 2000 AD has ushered in a new philosophy of equity, and a new approach, the primary health care approach. The National Health Plan (1983) proposed reorganization of primary health centres on the basis of one PHC for every 30,000 rural population in the plains, and one PHC for every 20,000 population in hilly, tribal and backward areas for more effective coverage. As on March 2014, 25,020 primary health centres have been established in the country.

Functions of the PHC

The functions of the primary health center in India cover all the 8 “essential” elements of primary health care as outlined in the Aina-Ata Declaration. They are:

1. Medical care
2. MCH including family planning
3. Safe water supply and basic sanitation
4. Prevention and control of local endemic diseases
5. Collection and reporting of vital statistics
6. Education about health
7. National Health Programmes - as relevant
8. Referral services
9. Training of health guides, health workers, local dais and health assistants
10. Basic laboratory services

It is proposed to equip the primary health centres with facilities for selected surgical procedures (e.g., vasectomy, tubectomy, MTP and minor surgical procedures) and for paediatric care. In order to revamp medical education (Rome Programme) towards the needs of the country and community care, these primary health centres have been attached to each of the IHS medical colleges.

Indian Public Health Standards for PHCs (29)

The IPHS for primary Health Centres has been prepared keeping in view the resources available with respect to functional requirement for PHCs with minimum standards such as building, manpower, instruments and equipments, drugs and other facilities etc. The standards prescribed are for a PHC covering 20,000-30,000 population with six beds, as all the block level PHCs are ultimately going to be upgraded as CHCs with 30 beds of providing specialized services.

The objectives of IPHS for PHCs are:

1. To provide comprehensive primary health care to the community through the Primary Health Centre.
2. To achieve and maintain an acceptable standard of quality of care.
3. To make the services more responsive and sensitive to the needs of the community.

Minimum requirements at primary health centre for meeting the IPHS

The assured services cover all the essential elements of preventive, promotive, curative and rehabilitative primary health care. This implies a wide range of services that include:

1. MEDICAL CARE: (a) OPD services: 4 hours in the morning and 2 hours in the afternoon/evening. Time schedule will vary from state to state. Minimum OPD attendance should be 40 patients per doctor per day; (b) 24 hours emergency services: appropriate management of injuries and accident. First-aid, stabilization of the condition of patient before referral, dog bite/snake bite/ scorpion bite cases, and other emergency conditions; (c) Referral services; and (d) In-patient services (6 beds).

2. MATERNAL AND CHILD HEALTH CARE: Antenatal care: (a) Early registration of pregnancy and minimum 3 antenatal check-ups; (b) Minimum laboratory investigations such as haemoglobin, urine albumin and sugar and RFT test for syphilis; (c) Nutrition and health counselling; (d) Supplementation of foetal acid and iron tablets and tetanus toxoid immunization; (e) Identification of high risk pregnancies and appropriate management; (f) Referral to First Referral Unit or other hospital in case of high risk pregnancy beyond the management capability of medical officer in PHC.

Intra-natal care: (a) 24 hours services for normal delivery; (b) Promotion of institutional delivery; (c) Conducting assisted deliveries including forceps and vacuum delivery whenever required; (d) Manual removal of placenta; and (e) Appropriate and prompt referral for cases needing specialist care.

Postnatal care: (a) A minimum of 2 post-partum home visits, first within 48 hours of delivery and 2nd within 7 days through sub-centre staff; (b) Initiation of breast-feeding within half-hour of delivery; (c) Education on nutrition, hygiene and contraception; and (d) Provision of facilities under Janani Suraksha Yojana.

New born care: (a) Essential newborn care; (b) Facilities and care for neonatal asystole; and (c) Management of neonatal hypothermia and jaundice.

Care of the child: (a) Emergency care of sick child including Integrated Management of Neonatal and Childhood Illness (IMNCI); (b) Care of routine childhood illness; (c) Promotion of breast-feeding for 6 months; (d) Full immunization of all infants and children against vaccine preventable diseases as per guidelines; and (e) Vitamin A prophylaxis.

3. Full range of family planning services including counseling and appropriate referral for couples having infertility.

4. Medical termination of pregnancy using manual vacuum aspiration technique, wherever trained personnel and facility exists.

5. Health education for prevention and management of RTI/STI.

6. Nutrition Services: Diagnosis and management of malnutrition, anemia and vitamin A deficiency and coordination with ICDS.

7. School health services.

8. Adolescent health care.

9. Disease surveillance and control of epidemics.

10. Collection and reporting of vital events.
11. Promotion of sanitation including use of toilet and appropriate garage disposal.

12. Testing of water quality and disinfection of water sources.

Revised National Tuberculosis Control Programme (RNTCP) All PHCs to function as DOTs Centres to deliver treatment as per RNTCP treatment guidelines through DOTs providers and treatment of common complications of TB and side effects of drugs, record and report on RNTCP activities as per guidelines.

National Programme for Control of Blindness: (a) Basic services: Diagnosis and treatment of common eye diseases; (b) Refraction services; and (c) Detection of cataract cases and referral for cataract surgery.

National Vector Borne Disease Control Programme: (a) Diagnosis of malaria cases, microscopic confirmation and treatment; (b) Cases of suspected dengue to be provided symptomatic treatment, hospitalization and case management as per the protocols; (c) Complete treatment to Kala-azar cases in Kala-azar endemic areas as per national policy; (d) Complete treatment of microfilaria positive cases with DEC and participation and arrangement of Mass Drug Administration (MDA) along with management of side reactions, if any. Morbidity management of lymphoedema cases.

National AIDS Control Programme: (a) IEC activities to enhance awareness and preventive measures about STIs and HIV/AIDS, Prevention of Parents to Child Transmission (PPTCT) services. (b) Organizing school health education programme. (c) Screening of persons practicing high-risk behaviour with one rapid test to be conducted at the PHC level and development of referral linkages with the nearest VCTC at the district hospital level for confirmation of HIV status of those found positive at one test stage in the high prevalence states. (d) Risk screening of antenatal mothers with one rapid test for HIV and to establish referral linkages with CHC or district hospital for PPTCT services in the six high HIV prevalence states of Tamil Nadu, Andhra Pradesh, Maharashtra, Karnataka, Manipur and Nagaland.

(e) Linkage with microcytosis centre for HIV-TB coordination.

(f) Condom promotion and distribution of condoms to the high-risk groups.

(g) Help and guide patients with HIV/AIDS receiving ART with focus on adherence. (h) Pre and post-test counselling of AIDS patients by PHC staff in high prevalence states.

14. Appropriate and prompt referral of cases needing special care and providing transport facilities either by PHC vehicle or other available referral transport. The funds should be made available for referral transport as per the provision under NRHM/RCH-II programme.

15. Record of vital events, reporting of births and deaths, and maintenance of all relevant records concerning services provided in PHC.

16. Training:

(i) Health workers and traditional birth attendants.

(ii) Initial and periodic training of paramedics in treatment of minor ailments.

(iii) Training of ASHAs.

(iv) Periodic training of doctors through continuing medical education, conferences, skill development training, etc. on emergency obstetric care.

(v) Training of ANM and LHV in antenatal care and skilled birth attendance.

(vi) Training under Integrated Management of Neonatal and Childhood Illness (IMNCI).

(vii) Training of pharmacist on AYUSH component with standard modules.

(viii) Training of AYUSH doctor in imparting health services related to National Health and Family Welfare programme.

17. Basic laboratory services

(i) Routine urinalysis, stool and blood tests.

(ii) Bleeding time, clotting time.

(iii) Diagnosis of RT/STDs with wet mounting, Grams stain, etc.

(iv) Spurt test in tuberculous (if designated as a microscopy center under RNTCP).

(v) Blood smear examination for malaria parasite.

(vi) Rapid tests for pregnancy.

(vii) RPR test for Syphilis/NETS surveillance.

(viii) Rapid diagnostic tests for typhoid (5 whip Dot) and malaria.

(v) Rapid test kit for fecal contamination of water.

(vii) Estimation of chlorine level of water using orthotolidine reagent.

18. Monitoring and supervision:

(i) Monitoring and supervision of activities of sub-centres through regular meetings/periodic visits, etc.

(ii) Monitoring of all National Health Programmes.

(iii) Monitoring of activities of ASHAs.

(iv) Medical officer should visit all sub-centres at least once a month.

(v) Health assistants male and LHV should visit sub-centres once a week.

19. Selected surgical procedures

The vasectomy, tubectomy (including laparoscopic tubectomy), MTP, hydrocelectomy and cataract surgeries as a component of the approach have to be carried out in a PHC having facilities of O.T.

20. Mainstreaming of AYUSH STAFFING PATTERN

The manpower that should be available in the PHC is as follows:

<table>
<thead>
<tr>
<th>Staff</th>
<th>Existing</th>
<th>Recommended</th>
</tr>
</thead>
<tbody>
<tr>
<td>Medical Officer</td>
<td>1</td>

4. Community Health Centres

As on 31st March 2014, 3,363 community health centres were established by upgrading the primary health centres, each community health centre covering a population of 80,000 to 1,23 lakh (one in each community development block) with 30 beds and specialists in surgery, medicine, obstetrics and gynaecology, and paediatrics with X-ray and laboratory facilities. For strengthening preventive and promotive aspects of health care, a new non-medical post called community health officer has been created at each community health centre. The community health officer is selected from amongst the supervisory category of staff at the PHC and district level with minimum of 7 years experience in rural health programmes. Some states have not accepted this scheme and have opted for a second medical officer (27).

The specialists at the community health centre may refer a patient directly to the State level hospital or the nearest/ appropriate Medical College Hospital, as may be necessary, without the patient having to go first to the sub-district or District Hospital.

Indian Public Health Standards for community health centres

In order to provide quality care in CHCs, Indian Public Health Standards (IPHS) are being prescribed to provide optimal expert care to the community and achieve and maintain an acceptable standard of quality of care. These standards would help monitor and improve the functioning of the CHCs.

Every CHC has to provide following services which are known as the assured services (39):

1. Care of routine and emergency cases in surgery:
   a. This includes incision and drainage, and surgery for hernia, hydrocele, appendicitis, haemorrhoids, fistula, etc.
   b. Handling of emergencies like intestinal obstruction, haemorrhage, etc.

2. Care of routine and emergency cases in medicine:
   Specific mention is being made of handling of all emergencies in relation to the national health programmes as per guidelines like dengue/DHF, cerebral malaria, etc. Appropriate guidelines are already available under each programme, which should be compiled in a single manual.

3. 24-hour delivery services, including normal and assisted deliveries.

4. Essential and emergency obstetric care including surgical interventions like caesarean sections and other medical interventions.

5. Full range of family planning services including laparoscopic services.

6. Safe abortion services.

7. Newborn care.

9. Other management, including nasal packing, tracheostomy, foreign body removal etc.

10. All the national health programmes (NHP) should be delivered through the CHCs. Integration with the existing programmes like blindness control. Integrated Disease Surveillance Project, is vital to provide comprehensive services.

a. RNTCP: CHCs are expected to provide diagnostic services through the microscopy centres which are already established in the CHCs, and treatment services as per the technical guidelines and operational guidelines for tuberculosis control.

b. HIV/AIDS Control Programme services will be provided.

c. National Vector-Borne Disease Control Programme: The CHCs are to provide diagnostic and treatment facilities for routine and complicated cases of malaria, filaria, dengue, Japanese Encephalitis and Kala-azar in the respective endemic zones.

d. National Leprosy Eradication Programme: The minimum services that are to be available at the CHCs are for diagnosis and treatment of cases and reactions of leprosy along with advice to patient on prevention of deformity.

e. National Programme for Control of Blindness: The eye care services that should be available at the CHC are diagnosis and treatment of common eye diseases, refraction services and surgical services including cataract by IOL implantation at selected CHCs optionally. 1 eye surgeon is being envisaged for every 5 lakh population.

f. Under Integrated Disease Surveillance Project, the related services include services for diagnosis for malaria, tuberculosis, typhoid and tests for detection of faecal contamination of water and chlorination level. CHC will function as peripheral surveillance unit and collect, analyze and report information to District Surveillance Unit. In outbreak situations, appropriate action will be initiated.

11. Others:

   a. Blood storage facility
   b. Essential laboratory services
   c. Referral (transport) services

Manpower for community health centres

The existing staff for CHC is as follows:

**Existing clinical manpower**

1. General Surgeon
2. Physician
3. Obstetrician / Gynaecologist
4. Paediatrician

**Existing support manpower**

Nurse - midwife * 1
Dresser (certified by Red Cross/St. Johns ambulance) 1
Pharmacist / compounder 1
Lab. technican 1
Radiographer 1
Ophthalmic assistant ** 1
Ward boy / nursing orderly 1
Sweepers 1
Chowkidar 1
OPD attendant 1
Statistical assistant / Data entry operator 1
OT attendant 1
Registration clerk 1

Total essential 21-22+2

* 1 ANM and 1 PHN for family welfare will be appointed under the ASHA scheme.

** Optomithic assistant may be placed wherever it does not exist through redeployment or contract basis.

*** Flexibility may rest with the state for recruitment of personnel as per requirements.
In order to provide round the clock clinical services, the revised IPHS staff pattern is as follows (40):

**Personnel** | **Strength** | **Desirable Qualifications**
--- | --- | ---
**Block Health Officer** - | Senior most specialists among the below mentioned specialties: (Physician/General Surgeon/Obstetrician & Gynae, Anaesthesiologist, Public Health/Obstetrician & Gynae, Ophthalmologist, Paediatrician)
**General Surgeon** | 1 | MS/DNB, (General Surgery)
**Obstetrician & Gynecologist** | 1 | MD/DNB/OGO (ObG)
**Paediatrician** | 1 | MD (Paediatrics)/DNB/DA
**Anaesthetist** | 1 | MD (Anaesthesia)/DNB/DA
**Public Health Manager** | 1 | Certificate course in Anesthesia for one year MD/PSM/MD (CHA)/MD Community Medicine or Post Graduation Degree with MBA MD/MS/DM/DS/DNB
**Eye surgeon** | 1 | (1 for every line CHCA)
**Dental Surgeon** | 1 | BDS
**General Duty Medical Officer** | 6 | MBBS
**Specialist of AVUSH** | 1 | Post Graduate in AVUSH
**Medical Officer of AVUSH** | 1 | Graduate in AVUSH
**Total** | 15/16 |

**Support manpower**

**Personnel** | **Strength**
--- | ---
Staff Nurse | 19**
Public Health Nurse (PHN) | 1*
ANM | 1*
Pharmacist/compounder | 3
Pharmacist-AVUSH | 1
Lab. Technician | 1
Radiographer | 2
Ophthalmic Assistant | 1
Doctor (certified by Red Cross/St. Johns Ambulance) | 2
Ward Boys/Nursing Orderly | 5
Sweepers | 5
Chowkidar | 1
Dhobi | 1
Mali | 1
Aya | 1
Peon | 2
OPD Attendant | 1
Registration Clerk | 2
Statistical Assistant/Data Entry Operator | 1
Account/Admin. Assistant | 1
OT Technician | 1
**Total** | 64

*Will be appointed under the ASHA scheme.

**For providing round the clock service at OT, labour room, casualty, male ward and female ward along with provision of leave reserve.

**JOB DESCRIPTION OF MEMBERS OF THE HEALTH TEAM**

1. **Medical Officer, PHC**
   - He is the captain of the health team at the primary health centre. He devotes the morning hours attending to patients in the out-door; in the afternoon he supervises the field work.
   - His tour programme is so designed as to cover all the basic health services including family planning.
   - He will plan and implement IIP as per guidelines and ensure maximum possible coverage of the population in the PHC. He will ensure proper storage of vaccine and maintenance of cold chain equipment. He will ensure adequate supplies of vaccine and miscellaneous items required for the effective implementation of IIP.
   - He will ensure proper implementation of DNCI as per guidelines.
   - He will visit schools in the PHC area at regular intervals and arrange for medical check up and immunization.
   - He will organize and conduct tuberculosis and vasectomy camps.
   - Organize training of all health personnel like ASHA, angerwadi worker, Dais etc.
   - He ensures that national health programmes are being implemented in their area properly.
   - He visits each subcentre regularly on fixed days and hours and provides guidance, supervision and leadership to the health team.
   - He spends one day in each month, organizing staff meetings at the primary health centre to discuss the problems and review the progress of health activities.
   - The success of a primary health centre depends largely on the team leadership which the medical officer is able to provide. The medical officer must be the planner, the promoter, the director, the supervisor, the coordinator as well as the evaluator.

2. **Medical Officer**
   - The second medical officer performs identical duties.

2. **Health worker Male and Female**
   - Under The Multipurpose Worker Scheme, one health worker male and one health worker male are posted at each sub-centre and are expected to cover a population of 5000 (3000 in tribal and hilly areas). However, health worker female limits her activities among 3500-5000 families.

A. **HEALTH WORKER FEMALE (HWF)**
   - She will carry out the following functions:
   - **Maternal and Child Health**
     - 1. Register and provide care to pregnant women throughout the period of pregnancy.
     - 2. Ensure that every pregnant woman makes at least 3 (three) visits for antenatal check-up.
     - 3. Test urine of pregnant women for albumin and sugar. Estimate haemoglobin level.
     - 4. Refer all pregnant women to PHC for RPR test for syphilis.
     - 5. Refer cases of abnormal pregnancy and cases with medical and gynaecological problems to Health Assistant Female (LHV) or the Primary Health Centre.
1.6 Conduct deliveries in her area when called for.
1.7 Supervise deliveries conducted by Dais and assist them whenever called in.
1.8 Refer cases of difficult labour and newborns with abnormalities, help them to get institutional care and provide follow-up to the patients referred to or discharged from hospital.
1.9 ANM will identify the beneficiaries, complete necessary formalities and obtain necessary approval from the competent authority before disbursement to the beneficiaries under Janani Suraksha Yojana (JSY), and by 7th of each month will submit accounts of the previous month in the prescribed format to be designed by the State. ANM will prepare a monthly work schedule in the meeting of all accredited workers to be held on every 3rd Friday of every month, which is mandatory. The guideline under JSY is to be followed.
1.10 Make at least two post-natal visits for each delivery happened in her area and render advice regarding care of the mother and care, feed of the newborn.
1.11 Assess the growth and development of the infant and take necessary action required to rectify the defect.
1.12 Educate mothers individually and in groups in better family health including maternal and child health, family planning, nutrition, immunization, control of communicable diseases, personal and environmental hygiene.
1.13 Assist Medical Officer and Health Assistant (Female) in conducting antenatal and postnatal clinics at the sub-centre.

2. Family Planning:
2.1 Utilize the information from the eligible couple and child register for the Family Planning programme. She will be responsible for maintaining eligible couple registers and updating at all times.
2.2 Spread the message of family planning to the couples and motivate them for family planning individually and in groups.
2.3 Distribute conventional contraceptives and oral contraceptives to the couples, provide facilities and to help prospective acceptors in getting family planning services, if necessary, by accompanying them or arranging for the DAI/ASHA to accompany them to hospital.
2.4 Provide follow-up services to female family planning acceptors, identify side effects, give treatment on the spot for side effects and minor complaints and refer those cases that need attention by the physician to the PHC/Hospital.
2.5 Establish female depot holders, and provide a continuous supply of conventional contraceptives to the depot holders.
2.6 Build rapport with acceptors, village leaders, ASHA, Dais and others and utilise them for promoting Family Welfare Programme.
2.7 Identify women leader(s) and help the Health Assistant (Female) to train them.
2.8 Participate in Mahila Mandal meetings and utilise such gatherings for educating women in Family Welfare Programme.

3. Medical Termination of Pregnancy:
3.1 Identify the women requiring help for medical termination of pregnancy and refer them to nearest approved institution.
3.2 Educate the community about the consequences of septic abortion and inform them about the availability of services for medical termination of pregnancy.

4. Nutrition:
4.1 Identify cases of malnutrition among infants and young children (birth to five years), give the necessary treatment and advice and refer serious cases to the nearest Health Centre.
4.2 Distribute Iron and Folic Acid tablets as prescribed to pregnant women, nursing mothers, and young children (up to five years) as per the guidelines.
4.3 Administer Vitamin A solution to children as per the guidelines.
4.4 Educate the community about nutritious diet for mothers and children.
4.5 Coordinate with Anganwadi Workers.

5. Universal Programme on Immunization (UIP):
5.1 Immunize pregnant women with tetanus toxoid.
5.2 Administer DPT vaccine, oral poliomyelitis vaccine, measles vaccine, hepatitis B vaccine and BCG vaccine to all infants and children, as per immunization schedule.
5.3 Ensure injection safety.

6. Dai Training:
6.1 List Dais in her area and involve them in promoting Family Welfare.
6.2 Help the Health Assistant (Female) / LHV in the training programme of Dais.

7. Communicable Diseases:
7.1 Notify the M.O. PHC immediately about any abnormal increase in cases of diarrhoea/dysentery, fever with rigors, fever with jaundice or fever with unexplained symptoms in which she comes across during her home visits, takes necessary measures to prevent their spread, and inform the Health Worker (male) to enable him to take further action.
7.2 If she comes across in case of fever during her home visits, she will take blood smear, administer presumptive treatment for malaria and inform the Health Worker (male) for further action.
7.3 Identify cases of skin patches, especially if accompanied by loss of sensation, which she comes across during her home visits and bring them to the notice of the Health Worker (male)/ MO (PHC).
7.4 Assist the Health Worker (male) in maintaining a record of cases in her area, who are under treatment for malaria, tuberculosis and leprosy, and check whether they are taking regular treatment, motivate defaulters to take regular treatment and bring these cases to the notice of the Health Worker (male) or Health Assistant (female).
7.5 Give oral rehydration solution to all cases of diarrhoea/dysentery/vomiting.
7.6 Education, counselling, referral, follow-up of cases STI/RTI, HIV/AIDS.
7.7 Where Filaria is endemic:
- Identification of cases of lymphoedema/elephantiasis and hydrocele and their referrals to PHC/CRC for appropriate management.
- Training of patients with lymphoedema/elephantiasis about care of feet and home based management remedies.
- Identification and training of drug distributors for mass drug distribution of DEC on National Filaria Day.

8. Vital Events
8.1 Record and report to the health authority of vital events including births and deaths, particularly of mothers and infants to the health authorities in her area.
8.2 Maintenance of all the relevant records concerning mothers, children and eligible couples in the area.

9. Record Keeping
9.1 Register (a) pregnant women from three months of pregnancy one per (b) infants zero to one year of age; and (c) women aged 15 to 44 years.
9.2 Maintain the prenatal and maternity records and child care records.
9.3 Prepare the eligible couple and child register and maintaining it up-to-date.
9.4 Maintain the records as regards contraceptive distribution, IUD insertion, couples sterilized, clinics held at the sub-centre and supplies received and issued.
9.5 Prepare and submit the prescribed weekly/monthly reports in time to the Health Assistant (Female).
9.6 While maintaining passive surveillance register for malaria cases, she will record:
- No. of fever cases.
- No. of blood slides prepared.
- No. of malaria positive cases reported.
- No. of cases given radical treatment.

10. Treatment of minor ailments
10.1 Provide treatment for minor ailments, provide first-aid for accidents and emergencies and refer cases beyond her competence to the Primary Health Centre/Community Health Centre or nearest hospital.
10.2 Provide treatment as per Indian System of Medicine (ISM), as needed, at the local level.

11. Team Activities
11.1 Attend and participate in staff meetings at Primary Health Centre/Community Development Block or both.
11.2 Coordinate her activities with the Health Worker (male) and other health workers including the Health volunteers/ASHA and Dais.
11.3 Coordinate with the PRI and Village Health and Sanitation Committee.
11.4 Meet the Health Assistant (Female) each week and seek her advice and guidance whenever necessary.
11.5 Maintain the cleanliness of the sub-centre.
11.6 Dispose medical waste as per the guidelines.
11.7 Participate as a member of the team in camps and campaigns.

B. HEALTH WORKER MALE (HWM) (38)

1. Record-keeping
He will;
1. Survey all the families in his area and collect general information about each village/rotaity in his area.
2. Prepare, maintain and utilize the records and village registers containing columns for recording particulars concerning IP, immunizations, vital events, environmental sanitation, other local health programmes, educational activities, services rendered and achievements, etc.

I. National health programmes
His duties pertaining to different national health programmes are as follows:

A. National vector borne disease control programme
I. Malaria
1. From each family, he shall enquire about:
   a) Presence of any fever cases
   b) Whether there was any fever case in the family in between his fortnightly visits
   c) Whether any guest had come to the family and had fever
   d) Whether any member of the family who had fever in between his fortnightly visit had left the village.
2. He shall collect thick and thin blood smears on one glass slide from case having fever or giving history of fever and enter details in Malaria Form-2 (MF-2) and put appropriate serial number on the slide.
3. He shall contact the ASHAs (Accredited Social Health Activist under NRHM) and other FTDs, if any, during their fortnightly visit to the village and (i) collect blood smears already taken by the ASHA, FTD (ii) also collect details of each case in MF-2 (iii) replenish both drugs and glass-slides and Rapid Diagnostic Kits (RDKs) and look into the account of consumption of Anti-malarial drugs and use of RDKs.
4. He shall dispatch blood smears along with MF-2 collected from the ASHA, FTD, multipurpose health worker (female), collected during their visit in his area, to the PHC Laboratory twice a week, or as instructed by the Medical Officer PHC.
5. He shall see the results obtained by the use of RDKs and verify the radical treatment administered by the ASHA, FTD, if any, during his visit.
6. He shall administer radical treatment to the positive cases as per drug schedule prescribed, and as per instructions issued by the Medical Officer PHC, and take laid down actions if toxic manifestations are observed in a patient receiving radical treatment with primaquine.
7. He shall contact the ASHA and FTD and inform the spray dates, and make request to motivate the community and prepare them for accepting the spray operations.
8. Assist the Health Supervisor (Male)/Health Assistant (Male) in supervising spraying operations and training of field spraying staff.

II. Kala-azar endemic areas
1. From each family, he will enquire about presence of any fever case of more than 15 days duration; whether any guest of the house had fever/Kala-azar; or any family member of the house/guest who had fever of more than 15 days duration left the village.
2. He will guide the suspected cases to the nearest PHC/CHC for diagnosis and treatment. He will keep a record of such cases and make sure that they take complete treatment.

3. Health education about Kala-azar disease

III. Japanese encephalitis (JE) endemic areas

1. From each family he will enquire about any fever case with symptoms of encephalitis and guide the suspected cases to the nearest PHC/CHC for diagnosis and treatment by a qualified medical officer.

2. He will keep the record of all the cases of JE in his area for follow-up.

3. Health education activities about the JE disease.

IV. Filariasis endemic areas

1. Identification of cases of lymphoedema/elephantiasis and hydrocele and their referrals to PHC/CHC for appropriate management.

2. Training of patients with lymphoedema/elephantiasis about care of feet and home based management remedies.

3. Identification and training of drug distributors for mass drug distribution of DEC on National Filariasis Day.

B. Leprosy eradication programme

1. Identify cases of skin patches, especially if accompanied by loss of sensation and refer these cases to M.O., PHC for further investigations diagnosis.

2. Check whether all cases of leprosy are taking regular treatment. Motivate defaulter to take regular treatment.

C. Revised national tuberculosis control programme

1. Identify persons especially 15 years and above, with prolonged cough or spitting of blood, and take sputum smears from these individuals. Refer cases to the M.O.PHC for further investigations.

2. Check whether all cases of tuberculosis are taking regular treatment. Motivate defaulter to take regular treatment.

3. Educate the community on various health education aspect of tuberculosis programme.

4. Assist the village Health Guide/ASHA and similar village health volunteers to carry-out DOTS activities, and to motivate the TB patients in taking regular treatment.

D. National blindness control programme

Identify and refer all cases of blindness including suspected cases of cataract to M.O., PHC.

E. Expanded programme on Immunization

1. Administer DPT vaccine, oral poliomyelitis vaccine, measles vaccine and BCG vaccine to all infants and children in his area in collaboration with health worker (female).

2. Assist the Health Worker Female in administering tetanus toxoid to all pregnant women.

3. Assist the Health Assistant Male in the school immunization programme.

4. Educate the people in the community about the importance of immunization against various communicable diseases.

F. Reproductive and child health programme (RCH)

1. Utilize the information from the eligible couple and child register for the family planning Programme.

2. Spread the message of family planning to the couples and motivate them for family planning individually and in groups.

3. Distribute conventional contraceptives and oral contraceptives to the couples.

4. Help prospective acceptors of sterilization in obtaining the services, if necessary, by accompanying them or arranging for the ASHA/dai to accompany them to the PHC/Hospital.

5. Provide follow-up services to male family Planning acceptors, and refer those cases that need attention by the physician to PHC/Hospital.

6. Build rapport with patients, acceptors, village leaders, ASHA, Dais and others and utilize them for promoting family welfare Programme.

7. Identify the male community leaders in each village of his area.

8. Assist the health supervisor male in training the leaders in the community and in educating and involving the community in Family Welfare Programme.

9. Identify the women requiring help for medical termination of pregnancy, refer them to the nearest approved institution and inform the health worker (female).

10. Educate the community on the availability of service for Medical Termination of Pregnancy.

11. Educate community on home management of diarrhoea and ORS.

13. Measures such as chlorination of drinking water to be carried out.

14. Proper sanitation to be maintained.

15. Encourage use of latrines.

16. Identify and refer cases of genital sore or urethral discharge or non-itchy rash over the body to medical officer.

II. Communicable diseases

1. Identify cases of diarrhoea/dysentery, fever with rash jaundice, encephalitis, diphtheria, whooping cough, tetanus, and acute eye infections and notify the Health Assistant Male and M.O. PHC immediately about these cases.

2. Carry out control measures until the arrival of the Health Assistant Male and assist him in carrying out these measures.

3. Give Oral Rehydration solution to all cases of diarrhoea/dysentery/vomiting.

4. Educate the community about the importance of control and preventive measures against communicable diseases and about the importance of taking regular and complete treatment.

III. Environmental sanitation

1. Chlorinate public water sources including wells at regular intervals.

2. Educate community on (a) the method of disposal of liquid wastes; (b) the method of disposal of solid wastes; (c) home sanitation, (d) advantage and use of sanitary type of latrines; (e) construction and use of smokeless chulhas.

3. Coordination with Village Health and Sanitation Committee.
IV. Primary medical care
Provide treatment for minor ailments, first-aid for accidents and emergencies and refer cases beyond his competence to the nearest hospital or PHC/CHC.

V. Health education
Educate the community about the availability of maternal and child health services and encourage them to utilize the facilities.

VI. Nutrition
1. Identify cases of malnutrition among infants and young children (0–5 years) in his area, give the necessary treatment and advice or refer them to the anganwadi for supplementary feeding and refer serious cases to the health centre.
2. Educate the community about the nutritious diet for mothers and children from locally available food.

VII. Vital events
1. Enquire about births and deaths occurring in his area, record them in the births and deaths register, sharing the information with ANM and report them to the Health Supervisor (Male)/Health Supervisor (Female).
2. Educate the community on the importance of registration of births and deaths.

VIII. Record Keeping
1. Survey all the facilities in his area and prepare/maintain maps and charts for the village.
2. Prepare, maintain and utilize family and village records.
3. Assist the Health Worker (Female)/ANM to prepare and maintain the eligible couple as well as maternal & child health register.
4. Maintain a record of cases in his area, who are under treatment for tuberculosis and leprosy.
5. Prepare and submit the prescribed monthly reports in time to the Health Supervisor (Male).
6. While maintaining passive surveillance register for malaria cases, he will record:
   a. No. of fever cases.
   b. No. of blood slides prepared.
   c. No. of malaria positive cases reported.
   d. No. of cases given radical treatment.

3A. Job responsibilities of Health Assistant (Female)
Note: Under the multipurpose workers scheme, a health assistant (female) is expected to cover a population of 30,000 (20,000 in tribal and hilly areas) in which there are six sub-centres, each with one health worker (female).

The health assistant (female) will carry out the following functions:
1. Supervision and guidance
   1.1 Supervise and guide the health worker(female) in the delivery of health care services to the community.
   1.2 Strengthen the knowledge and skills of the health worker (female).
   1.3 Help the health worker (female) in improving her skills in working in the community.
   1.4 Help and guide the health worker (female) in planning and organizing her programme of activities.

1.5 Visit each sub-centre at least once a week on a fixed day to observe and guide the health worker (female) in her day-to-day activities.
1.6 Assess periodically the progress of work of the health worker (female), and submit an assessment report to the medical officer of the primary health centre.
1.7 Carry out supervisory home visits in the area of the health worker (female).

2. Team work
2.1 Help the health worker to work as part of the health team.
2.2 Co-ordinate her activities with those of the health assistant (male) and other health personnel including the ANM.
2.3 Co-ordinate the health activities in her area with the activities of workers of other departments and agencies, and attend meetings at block level.
2.4 Conduct regular staff meetings with the health workers in coordination with the health assistant (male).
2.5 Attend staff meetings at the primary health centre.
2.6 Assist the medical officers of the primary health centre in the organization of the different health services in the area.
2.7 Participate as a member of the health team in mass camps and campaigns in health programmes.

3. Supplies, equipment and maintenance of sub-centre
3.1 In collaboration with the health assistant (male), check at regular intervals the stores available at the sub-centre and help in the procurement of supplies and equipment.
3.2 Check that the drugs at the sub-centre are properly stored and that the equipment is well maintained.
3.3 Ensure that the health worker (female) maintains her general kit and midwifery kit in the proper way.
3.4 Ensure that the sub-centre is kept clean and is properly maintained.

4. Records and reports
4.1 Scrutinize the maintenance of records by the health worker (female) and guide her in their proper maintenance.
4.2 Maintain the prescribed records and prepare the necessary reports.
4.3 Review reports received from the health workers (female), consolidate them, and submit periodical reports to the medical officer of the primary health centre.

5. Where Kala-azar is endemic, her additional duties are:
5.1 She should check minimum of 10% of the houses in a village to verify that the health worker (female) really visited those houses and carried her job of identifying suspected Kala-azar cases and ensuring complete treatment has been done properly.
5.2 She will carry with her the proper record forms, diary and guidelines for identifying suspected Kala-azar cases; and she will be responsible along with Health Assistant (Male) for ensuring complete treatment of Kala-azar patients in her area.
5.3 She will be responsible along with health assistant (male) for ensuring complete coverage during the spray activities and search operation.
4. She will also undertake health education activities particularly through interpersonal communication, arrange meetings with leaders and organizing and conducting training of community leaders with the assistance of health team.

5. Through spot checking, she will ensure that health worker (female) maintains up-to-date eligible couple register.

6. Provide IUD services and their follow-up.

7. Assist medical officer PHC in organizing family planning camps.

11. Nutrition

1. Identify cases of malnutrition among infants and young children (zero to five years), give the necessary treatment and advice and refer serious cases to the primary health centre/community health centre.

2. Ensure that iron and folic acid tablets and vitamin A solution are distributed to the beneficiaries.

3. Educate the expectant mother regarding breast feeding.

12. Immunization

1. Supervise the immunization of all pregnant women and children (0–5 years).

2. She will guide the health worker (female) to procure supplies, organize immunization camps, provide guidance for maintaining cold chain, storage of vaccine and health education about immunization programme.

13. Acute respiratory infection

1. Ensure early diagnosis of pneumonia cases.

2. Provide suitable treatment to mild/moderate cases of ARI.

3. Ensure early referral in doubtful/severe cases.

14. School health

Help medical officer in school health services.

15. Primary medical care

1. Provide treatment for minor ailments, provide first-aid for accidents and emergencies, and refer cases beyond her competence to the primary health centre or nearest hospital.

2. Attend to cases referred by the health workers and refer cases beyond her competence to the primary health centre or nearest hospital.

16. Health education

1. Carry out educational activities for MCH, family planning, nutrition and immunization with the assistance of the health worker (female).

2. Arrange group meetings with leaders and involve them in spreading the message for various health programmes.

3. Organize and conduct training of woman leaders with the assistance of health worker (female).

4. Organize and utilize mobil mandals, teachers and other women in the community in the family welfare programmes.

38. Specific Job functions of Health Assistant (Male) (39)

1. Malaria

1. Supervise the work of Health Worker Male during concurrent visits.

2. Check minimum of 10% of the houses in the village.

3. Collect thick and thin smears from any fever case he come across and will administer presumptive treatment of prescribed dosage of anti-malaria drugs.
IV. Communicable diseases
1. Be alert to the sudden outbreak of epidemics of diseases such as diarrhea/dysentery; fever with rash, jaundice, encephalitis, diphtheria, whooping cough or tetanus, acute eye infections and take all possible remedial measures.
2. Take the necessary control measures when any notifiable disease is reported to him. Carry out the destruction of stray dogs with the help of the Health Worker Male.

III. Leprosy
1. Ensure that all cases of Leprosy take regular and complete treatment and inform the Medical Officer PHC about any defaulters to treatment.

IV. Tuberculosis
Ensure that all cases of tuberculosis take regular and complete treatment and inform the M.O. PHC about any defaulters to treatment.

V. Environmental sanitation
Help the community in the construction of:
(a) safe water source
(b) soakage pits
(c) kitchen garden
(d) manure pits
(e) compost pits
(f) Sanitary latrines
(g) smokeless chulhas and supervise their construction. Supervise the chlorination of water source including wells.

VI. Expanded programme on Immunization
1. Conduct immunization of all school going children with the help of the Health Worker Male.
2. Supervise the immunization of all children from one to five years.

VII. Family planning
1. Personally motivate resistant cases for family planning.
2. Guide the Health Worker Male in establishing male depot holders with the assistance of the Health Worker Male and supervise the functioning.
3. Assist M.O.PHC in organization of Family Planning camps and drives.
4. Provide information on the availability of services for medical termination of pregnancy and refer suitable cases to the approved institutions.
5. Ensure follow-up of all cases of vasectomy, tubectomy, IUD and other Family Planning acceptors.

VIII. Nutrition
1. Ensure that all cases of malnutrition among infants and young children (0-5 years) are given the necessary treatment and advice and refer serious cases to the PHC.
2. Ensure that Iron and Folic Acid and Vitamin A are distributed to the beneficiaries as prescribed.

IX. Control of blindness
All cases of blindness including suspected cases of cataract be referred to Medical Officer of Primary Health Centre.

4. Accredited Social Health Activist (ASHA)
The job responsibility of ASHA, and the integration of her role with anganwadi and ANM are described in detail on page 449.

HOSPITALS
Apart from the primary health centres, the present organization of health services of the Government sector consists of rural hospitals, sub-divisional/tahal/tauka hospitals, district hospitals, specialist hospitals and teaching institutions.

(a) Rural hospitals: It is now proposed to upgrade the rural dispensaries (allopathic/traditional system of medicine) to primary health centres. At present a good number of PHCs are located at tahsil/Sub-divisional/tauka headquarters which also have hospitals. Such PHCs may be shifted to the interior rural areas. It is proposed to convert the Sub-divisional hospitals into Sub-divisional health centers so as to cover a population of 5 lakhs (15). These centers will have an epidemiological wing attached to them.

(b) District hospitals: There are proposals to convert the district hospital into District Health Centre (15). A hospital differs from a health centre in the following respects:
(a) in a hospital, services provided are mostly curative; in a health centre, the services are preventive, promotive and curative – all integrated; (b) a hospital has no catchment area, i.e., it has no definite area of responsibility. Patients may be drawn from any part of the country. A health centre, on the other hand, is responsible for a definite area and population; (c) the health team in a health centre is a optimum “mix” of medical and paramedical workers; in a hospital, the team consists of only the curative staff, i.e., doctors, compounders, nurses, etc. Today, the role of the hospital in the community is being debated. The current opinion is that the hospital should not remain an “ivory tower of disease” but should take a role in providing health services to the community. Experience has shown that the health of the community cannot be improved by multiplying hospitals alone.

Under the Multipurpose Workers Scheme, it has been suggested to the States to have an integrated set-up at the district level by having a Chief Medical Officer of the district with 3 Deputy CMO’s (drawn from the cadre of existing Civil Surgeons, District Health Officers and District Family Welfare Officers) with each of the Deputy CMO being in charge of one-third of the district for all the health, Family Welfare and MCH programmes. It has been suggested that the district pattern should be based on the number of PHCs.

HEALTH INSURANCE
There is no universal health insurance in India. Health insurance is at present limited to industrial workers and their families. The Central Government employees are also covered by the health insurance, under the banner “Central Govt. Health Scheme”.

Employees State Insurance Scheme
The ESI scheme, introduced by an Act of Parliament in 1948, is a unique piece of social legislation in India. It has introduced for the first time in India the principle of contribution by the employer and employee. The Act provides for medical care in cash and kind, benefits in the contingency of sickness, maternity, employment injury, and pension for dependents on the death of worker because of employment injury. The Act covers employees drawing wages not exceeding Rs. 15,000 per month (see page 815 for details).

Central Government Health Scheme
The Central Government Health Scheme (previously
known as Contributory Health Service Scheme) for the Central Government employees was first introduced in New Delhi in 1954 to provide comprehensive medical care to Central Government employees. The scheme is based on the principle of cooperative effort by the employee and the employer to bear the central share of both.

The facilities under the scheme include (a) out-patient care through a network of dispensaries (b) supply of medicines (c) hospitalisation (d) domiciliary visits (e) hospitalization facilities at Government as well as private hospitals recognized for the purpose (f) specialist consultation (g) paediatric services including Immunization (h) antenatal, natal and postnatal services (i) emergency treatment (j) supply of optical and dental aids at reasonable rate, and (k) family welfare services.

The scope of the scheme has been gradually extended over the years to cover cities outside Delhi as well as other sectors of population such as the employees of the autonomous organizations, retired Central Govt. servants, widows receiving family pension, Members of Parliament, Ex-Governors and retired Judges. The scheme now covers besides Delhi, the cities of Mumbai, Allahabad, Meerut, Kanpur, Patna, Kolkata, Nagpur, Chennai, Hyderabad, Bangalore, Jaipur, Pune, Lucknow, Ahmedabad, Bhubaneswar, and Jabalpur.

The scheme which started with 16 allopathic dispensaries in 1954 covering 2.3 lakhs beneficiaries has now 320 dispensaries/hospitals is various systems of medicine and provides service to about 42.76 lakhs beneficiaries. There is also a yoga centre under the scheme in Delhi.

The Employees State Insurance Scheme and the Central Government Health Scheme cover two large groups of wage earners in the country. Evidence from organized medical insurance schemes, and are providing reasonable medical care plus some essential preventive and promotive health services. Experience in other countries has shown that health insurance is a logical step towards nationalization of health services.

OTHER AGENCIES

Defence Medical Services

Defence services have their own organization for medical care to defence personnel under the banner "Armed Forces Medical Services". The services provided are integrated and comprehensive embracing preventive, promotive and curative services.

Health Care of Railway Employees

The Railways provide comprehensive health care services through the agency of Railway Hospitals, Health Units and clinics. Environmental sanitation is taken care of by Health Inspectors in big stations. A chief Health Inspector supervises the division's work. Health check-up of employees is provided at the time of entry into service, and thereafter at yearly intervals. There are lady medical officers, health visitors and midwives who look after the NCH and School Health Services. Specialists' services are also available at the Divisional Hospitals.

PRIVATE AGENCIES

In a mixed economy such as India's, private practice of medicine provides a large share of the health services available. There has been a rapid expansion in the number of qualified allopathic physicians from about 50,000 at the time of Independence to about 7,67 lakhs in 2005 and the doctor-population ratio for the country as a whole is 1 : 1428. The general practitioners constitute 70 per cent of the medical profession. Most of these tend to congregate in urban areas. The private hospital and diagnostic services. These services are available to those who can pay. The private sector of the health care services is not organized. Some statutory bodies like the Medical Council of India and the Indian Medical Association regulate some of the functions and activities of the large body of private registered medical practitioners.

INDIGENOUS SYSTEMS OF MEDICINE

The practitioners of indigenous systems of medicine (e.g., Ayurveda, Siddha, Homoeopathy, etc.) provide the bulk of medical care to the rural people. Ayurvedic physicians alone are estimated to be about 4.38 lakhs (27). Studies indicate that nearly 90 per cent of Ayurvedic physicians serve the rural areas. Most of them are local residents and remain very close to the people socially and culturally. In recent years there has been considerable state patronage to foster these systems of medicine. Many Ayurvedic dispensaries are state-run. The Govt. of India has established a National Institute of Ayurveda in Jaipur and a National Institute of Homoeopathy in Kolkata. A Central Council of Indian Medicine was established in 1971 to prescribe minimum standards of education in Indian medicine. The Govt. of India is studying the question of how indigenous systems of medicine could best be utilized for more effective or total health coverage.

VOLUNTARY HEALTH AGENCIES

The voluntary health agencies occupy an important place in the field of health care. The voluntary health agency may be defined as an organisation that is administered by an autonomous board which holds meetings, collects funds for its support chiefly from private sources and expends money, whether with or without paid workers, in conducting a programme directed primarily to furthering the public health by providing health services or health education, or by advancing research or legislation for health, or by a combination of these activities (42). The one country where voluntary health agencies have developed and flourished to an enormous extent is the United States. Even in 1946, it was estimated that there were more than a thousand voluntary agencies in the United States. The voluntary health agencies have been compared to "motor trucks" which can penetrate the by-ways, and the official agencies to "Railway Trunk Lines" which must run on tracks established by law (43).

FUNCTIONS

The types of service rendered by voluntary health agencies have been classified as: (a) SUPPLEMENTING THE WORK OF GOVERNMENT AGENCIES: It is well known that government agencies cannot provide complete service because they operate under financial and statutory restrictions. The voluntary health agencies can help strengthen the work of government agencies by lending personnel, or by contributing funds for special equipment, supplies or services. (b) PIONEERING: The voluntary health agencies are in a position to explore ways and means of doing new things. Research is one form of pioneering. When the research is successful and bear fruit, the government in the agencies can step in and take over the project for the benefit of the
larger numbers. The family planning programme in India is an example of pioneering by the voluntary agencies which has achieved a national goal. (c) EDUCATION: There is unlimited scope for health education in India. The government agencies are active in this field, but they are supplemented by voluntary efforts on the part of the people. (d) DEMONSTRATION: By putting up demonstrations and informative displays, the voluntary agencies have advanced the cause of public health. The demonstration of bore hole latrines by the Rockefeller Foundation to solve the problem of leprosy in India is a case in point. The bore hole latrine and its modifications have since become an essential part of the environmental sanitation programme of the government. (e) GUARDIAN OF THE WORK OF GOVERNMENT AGENCIES: By setting a good example the voluntary health agencies can always guide and criticise the work of the public health agencies. (f) ADVANCING HEALTH LEGISLATION: The voluntary agencies can also mobilise public opinion and advance legislation on health matters for the benefit of the whole community.

VOLUNTARY HEALTH AGENCIES IN INDIA (44)

1. INDIAN RED CROSS SOCIETY: The Indian Red Cross Society was established in 1920. It has a network of over 400 branches all over India. It has been executing programmes for the promotion of health, prevention of disease and mitigation of suffering among the people. Its first spearhead was the movement in the face of each epidemic. The Red Cross Society immediately mobilises all its resources and goes to the rescue of the affected people. (b) MILK AND MEDICAL SUPPLIES: A number of government hospitals, dispensaries, maternity and child welfare centres, schools and orphanages receive assistance from the society every year. The assistance given consists mainly of milk powder, medicines, vitamins and other supplies. (c) ARMED FORCES: The care of the sick and the wounded among the members of the forces is one of the main obligations of the Red Cross. The Society runs a well-equipped hospital, the 'Red Cross Home' at Bangalore, the only one of its kind in India, which was founded in 1920. The society continues to look after the sick and the injured of the forces at a number of hospitals and dispensaries in various parts of the country. (d) MATERI ONAL AND CHILD WELFARE SERVICES: The Red Cross is a large number of maternity and child welfare centres all over India, either permanently by or are affiliated to the Red Cross. There is a bureau of Maternity and Child Welfare, which provides technical advice and financial aid to schemes for establishing model maternity and child welfare centres. (e) FAMILY PLANNING: Several States in India are running family planning clinics under the auspices of the Indian Red Cross. (f) BLOOD BANK AND FIRST AID: Some of the State branches have started blood banks. The St. John Ambulance Association in India which is part of the Red Cross has trained a large number of men and women in first aid, home nursing and allied subjects.

2. HIND KUSH IVARAN SANGH: The Hind Kush Nirvan Sangh was founded in 1950 with its headquarters in New Delhi. Its predecessor was the Indian Council of the British Empire Leprosy Relief Association (B.E.L.R.A.) which was renamed as LEPIRA in 1950. The programme of work of the Sangh includes rendering of financial assistance to various leprosy homes and hospitals, health education through publications and posters, training of medical workers and physiotherapists, conducting research and field investigations, organizing All-India Leprosy Workers Conferences and publication of 'Leprosy in India', a quarterly journal. The Sangh has branches all over India and works in close cooperation with the Government and other voluntary agencies.

3. INDIAN COUNCIL FOR CHILD WELFARE: The Indian Council for Child Welfare was established in 1952. It is affiliated with the International Union for Child Welfare. Since its formation, the I.C.C.W. has built up a network of State Councils and district councils all over the country. The services of I.C.C.W. are devoted to secure for India's children those opportunities and facilities, by law and order, which are necessary to enable them to develop physically, mentally, morally, spiritually and socially in a healthy and normal manner and in conditions of freedom and dignity.

4. TUBERCULOSIS ASSOCIATION OF INDIA: The Tuberculosis Association of India was formed in 1939. It has branches in all the States in India. The activities of this Association comprise organizing a T.B. seal campaign every year to raise funds, training of doctors, health visitors and social workers in multiphasis-osis work, promotion of health education and promotion of consultations and conferences. The following institutions are under the management of the Association: The New Delhi Tuberculosis Centre, the Lady Lilhough Sanatorium at Kaisauli, the King Edward VII Sanatorium at Dharapuram and the Tuberculosis Hospital at Mehrauli.

5. BHARAT SEVA SAMAJ: The Bharat Sevak Samaj which is a non-political and non-official organization was formed in 1952. One of the prime objectives of the Bharat Sevak Samaj (B.S.S.) is to help people to achieve health by their own actions and efforts. The B.S.S. has branches in all the States and in nearly all the districts. Improvement of sanitation in villages is one of the important activities of the B.S.S.

6. CENTRAL SOCIAL WELFARE BOARD: The Central Social Welfare Board is an autonomous organization under the general administrative control of the Ministry of Education. It was set up by the Government of India in August 1953. The functions of the Board are: (1) surveying the needs and requirements of voluntary welfare organizations in the country (2) promoting and setting up of social welfare organizations on a voluntary basis (3) rendering of financial aid to deserving organizations and institutions. The Board initiated in 1968, "Family and Child Welfare Services" in rural areas for the welfare of women and children. The activities of these projects comprise teaching of craft, social education, literacy classes, maternal aid for women, distribution of milk, baloddis, and organisation of play centres for children. The Board has also started a scheme of Industrial Cooperatives to help the lower-middle class women in urban areas supplement their family income by doing paid work.

7. THE KASTURBA MEMORIAL FUND: Created in commemoration of Kasturba Gandhi, after her death in 1948, the Fund was raised with the main object of improving the lot of women, especially in the villages, through gram-sevillas. The trust has nearly a crore of rupees and is actively engaged in various welfare projects in the country.

8. FAMILY PLANNING ASSOCIATION OF INDIA: The Family Planning Association was formed in 1949 with its
headquarters at Mumbai. It has done pioneering work in propagating family planning in India. The Association has branches all over the country. These branches are running family planning clinics with grants-in-aid from the Government. The Association has trained several hundred doctors, health visitors and social workers. One of the activities of the Headquarters is to answer enquiries on family planning by correspondence or by personal interviews.

9. ALL INDIA WOMEN'S CONFERENCE: It is the only women's voluntary welfare organisation in the country. Established in 1926, it has now branches all over the country. Most of the branches are running M.H.C. Clinics, Medical centres, and adult education centres, milk centres and family planning clinics.

10. THE ALL-INDIA BLIND RELIEF SOCIETY: The All-India Blind Relief Society was established in 1946 with a view to coordinate different institutions working for the blind. It organises eye relief camps and other measures for the relief of the blind.

11. PROFESSIONAL BODIES: The Indian Medical Association, All India Leprosy Association, All India Dental Association, The Trained Nurses Association of India are all voluntary agencies of men and women who are qualified in their respective specialities and possess registrable qualifications. These professional bodies conduct annual conferences, publish journals, arrange scientific sessions and exhibitions, foster research, set up standards of professional education and organise relief camps during periods of natural calamities.

12. INTERNATIONAL AGENCIES: The Rockefeller Foundation, Ford Foundation, and CARE (Cooperative for Assistance & Relief Everywhere) are examples of voluntary international health agencies.

HEALTH PROGRAMMES IN INDIA

Since India became free, several measures have been undertaken by the National Government to improve the health of the people. Prominent among these measures are the NATIONAL HEALTH PROGRAMMES, which have been launched by the Central Government for the control/eradication of communicable diseases, improvement of environmental sanitation, nutrition, control of population and rural health. Various international agencies like WHO, UNICEF, UNFPA, World Bank, as also a number of foreign agencies like SIDA, DANIDA, NORAD and USAID have been providing technical and material assistance in the implementation of these programmes. A brief account of these programmes which are currently in operation is given in chapter 7.

“Nothing on earth is more international than disease”, said Paul Rusell. Health and disease have no political or geographical boundaries. Disease in any part of the world is a constant threat to other parts. History is replete with examples of the spread of pestilences – particularly of plague and cholera, along trade routes. In order to prevent the spread of disease from one country to another, many attempts were made in the past by individual rulers and States to place barriers against infection by detection and isolation of incoming travellers. In the 14th century, a procedure known as “quarantine” was introduced in Europe to protect against the importation of plague. Ships, crews, travellers and cargoes, suspected of harbouring infection, were detained for a 40-day period. The underlying idea was that the passage of time would give dormant disease to manifest itself or die out. Quarantine soon became an established practice in many countries, and different countries adopted different quarantine procedures. This was the origin of international health work.

Quarantine failed in its objective because of the lack of scientific knowledge regarding the causation and mode of spread of disease. Opposition to quarantine came from several quarters because the 40-day detention obstructed and caused serious inconveniences to international trade and travel. It became necessary for international agreement and cooperation on quarantine matters to control communicable diseases. International conferences were held and organizations set up for discussion, agreement and cooperation on matters of international health. A brief account of these endeavours and of the early health organizations which preceded the World Health Organization is given below.

First International Sanitary Conference (1851)

The origin of international health cooperation dates back to 1851, when an international sanitary conference – the first of its kind – was convened in Paris. The Conference was attended mainly by European countries – Austria, France, Great Britain, Greece, Portugal, Russia, Spain and four Sovereign States (Sardinia, the two Sicilies, the Papal States, Tuscany) that were later to form a united Italy (1). Turkey also participated in this Conference. The objective of this Conference was very limited i.e., to introduce some order and uniformity into quarantine measures which varied from country to country. The conference lasted six months with no lasting results. Some members opposed quarantine, and some took an intermediate position. Despite the many difficulties involved, an international sanitary code was prepared, comprising 137 articles dealing with cholera, plague and yellow fever (2). But, the sanitary code never came into force as it was ratified by only three countries – France, Portugal and Sardinia of which Portugal and Sardinia withdrew in 1865. Thus the conference was regarded as having ended in failure. The 1851 conference was followed in rapid succession by further conferences – no less than 10 conferences took place between 1851 and 1902, but they were equally unable to reach an agreement on quarantine measures (2).

Pan American Sanitary Bureau (1902)

The next important milestone in international health work was the establishment of Pan American Sanitary Bureau (PASB) in 1902 in the Americas. It was primarily intended to coordinate quarantine procedures in the American States. In 1924 an important document was signed by the American Republic namely “The Pan American Sanitary Code” which is still in force between the States. In 1947, the Bureau was reorganized and the organization was called the Pan American Sanitary Organization (PASO). In 1949, an agreement was reached whereby the PASO would serve as the WHO Regional Office for the Americas. In 1958, the name was changed to Pan American Health Organization (PAHO) (3). Over the years, PAHO has grown from a small information centre to a major health agency with its headquarters in Washington, D.C.

The Pan American Sanitary Bureau was the World’s first international health agency (4).

Office International D’Hygiène Publique (1907)

At the 1903 International Sanitary Conference, a step of fundamental importance was taken, that is, to establish a permanent International Health Bureau (1). This decision was probably influenced by the fact that the American republics had already established a similar bureau, the Pan American Sanitary Bureau in 1902. According to In 1907, the “Office International d’Hygiène Publique” (OHIP), generally known as the “Paris Office” was created to disseminate information on communicable diseases and to supervise international quarantine measures. At its inception, the OHIP was predominantly European, but later on a considerable degree of cooperation grew up between OHIP and PASB. Sixty other countries, including British India, joined the OHIP, giving the Office an international character (5).

Although the OHIP had no field staff to undertake investigation of epidemics it did remarkable work in disseminating knowledge of communicable diseases and their control and also information on a variety of health problems of world-wide interest. The OHIP continued to exist until 1950, by which time its responsibilities had been taken over by the WHO.
The Health Organization of the League of Nations (1923)

After the first World War (1914-18), the League of Nations was established to build a better world. It included a ‘Health Organization’ to “take steps in matters of international concern for the prevention and control of disease”. Although the League of Nations was a failure on the political side, its Health Organization, which was established in 1923, did creditable work. Not confining itself to quarantine regulations and epidemiological information or even larger problems of epidemic diseases, the Health Organization of the League branched out into such matters as nutrition, housing and rural hygiene, the training of public health workers and the standardization of certain biological preparations. The League analysed epidemiological information received, and started the series of periodical epidemiological reports now issued by the WHO. It also established the Far Eastern Bureau at Singapore and plans were laid down for technical studies (including the use of expert committees) which are substantially followed by the WHO.

The WHO owes much to the work done and methods devised by the Health Organization of the League. It may be mentioned that efforts to amalgamate the OIHP, PASB and the Health Organization of the League of Nations proved a failure, and all the three organizations were co-existing during the years between the two World Wars. In 1939, the League of Nations was dissolved but its Health Organization in Geneva continued to do best as it could with requests for information and the publication of the Weekly Epidemiological Records was never suspended.

The United Nations Relief and Rehabilitation Administration (UNRRA) was set up in 1943 with the general purpose of organizing recovery from the effects of the Second World War. The UNRRA had a health division to care for the health of the millions of displaced persons, to restore and help services and to revive the machinery for international interchange of information on epidemic diseases. UNRRA did outstanding work of preventing the spread of typhus and other diseases, so that they never reached serious epidemic levels anywhere. Similarly, UNRRA’S assistance to malaria control in such countries as Greece and Italy, where war had disrupted peace-time anti-malaria services, was on an immense scale. The world renowned campaign for the eradication of malaria from Sarinza was begun as a joint effort of UNRRA, the Rockefeller Foundation and UNNRA.

At the end of 1946, UNRRA terminated its official existence and its health activities and financial assets were taken over by the Interim Commission or the WHO.

Birth of the WHO

The WHO has its origin in April 1945, during the conference held at San Francisco to set up the United Nations. The representatives of Brazil and China proposed that an international health organization should be established and that a conference to frame its constitution should be convened. The constitution was drawn up at an international health conference in New York in 1946. The same conference set up an ‘Interim Commission’ to prepare the ground for the new organization and to carry out urgent tasks until the WHO constitution had been accepted by the required number of UN Member States. The ratifications were secured by July 1948; the formal existence of the WHO as a specialized agency began on that date. The formation of WHO represents the culmination of efforts to establish a single worldwide inter-governmental health agency.

WORLD HEALTH ORGANIZATION

The World Health Organization is a specialized, non-political, health agency of the United Nations, with headquarters at Geneva. In 1946, the constitution was drafted by the ‘Development Planning Committee’ under the chairmanship of Rene Sand, and was approved in the same year by an International Health Conference of 51 nations in New York. The constitution came into force on 7th April, 1948 which is celebrated every year as “World Health Day”. A World Health Day theme is chosen each year to focus attention on a specific aspect of public health.

Objective

The objective of the WHO is “the attainment by all people of the highest level of health” which is set out in the preamble of the Constitution. The current objective of WHO is the attainment by all people of the world a level of health that will permit them to lead a socially and economically productive life. The preamble of the Constitution states:

“Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity.

The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition.

The health of all peoples is fundamental to the attainment of peace and security and is dependent upon the fullest cooperation of individuals and States.

The achievement of any State in the promotion and protection of health is of value to all countries and exchange of experience in the promotion of health, and control of disease, especially communicable disease, is a common danger.

Healthy development of the child is of basic importance; the ability to live harmoniously in a changing total environment is essential to such development.

The extension to all people of the benefits of medical, psychological and related knowledge is essential to the fullest attainment of health.

Informed opinion and active cooperation on the part of the public are of the utmost importance in the improvement of the health of the people.

Governments have a responsibility for the health of their peoples which can be fulfilled only by the provision of adequate health and social measures.

The WHO is unique among the UN Specialized Agencies in that it has its own constitution, own governing bodies, own membership and own budget. It is part of, but not subordinate to, the United Nations.

Two major policy developments have influenced the WHO. First, the Alma-Ata Conference in 1978 on primary health care which provided both WHO and UNICEF with a common charter for health and, secondly, the Global Strategy for Health for All by 2000, and more recently Millennium Development Goal.
Membership
Membership in WHO is open to all countries. While most countries are members of both the UN and of WHO, there are some differences. For example, Switzerland is a member of WHO, but not of the United Nations. Territories which are not responsible for the conduct of their international relations may be incommunicable disease. The WHO collects and disseminates epidemiological information on diseases subject to International Health Regulations and occasionally other communicable diseases of international importance through an Automatic Telex Reply Service (ATRS) and the "Weekly Epidemiological Record" (WER). The latter contains more complete details and brief reviews of communicable diseases of international importance. Member States can also make use of the "WHO Emergency Programme for Epidemics" whenever necessary. The aim of International Health Regulations is to ensure maximum security against international spread of disease with the minimum interference with traffic. The WHO has also paid attention in its programme of work to non-communicable disease problems such as cancer, cardiovascular diseases, genetic disorders, diabetes, blindness, mental disorders, drug addiction and dental diseases. The activities of WHO have also branched out into the fields of vector biology and control, immunology, quality control of drugs and biological products, drug evaluation and monitoring and health laboratory technology as these activities are relevant to the control of both communicable and non-communicable diseases. Immunization against common diseases of childhood (Expanded Programme on Immunization) is now a priority programme of the WHO.

2. DEVELOPMENT OF COMPREHENSIVE HEALTH SERVICES
WHO's most important single function is to promote and support national health policy development and the development of comprehensive national health programmes. This broad field of endeavour encompasses a wide variety of activities such as organizing health systems based on primary health care, the development of health manpower and utilization, building of long-term national capability, particularly in the areas of health infrastructure development, and managerial capabilities (including health research and training). Appropriate Technology for Health (ATH) is another new programme launched by the WHO to encourage self-sufficiency in those health problems. The new programme is part of WHO's efforts to build up primary health care.

3. FAMILY HEALTH
Family health is one of the major programme activities of WHO since 1970, and is broadly subdivided into maternal and child health care, human reproduction, nutrition and health education. The chief concern is improvement of the quality of life of the family as a unit.

4. ENVIRONMENTAL HEALTH
Promotion of environmental health has always been an important activity of WHO. WHO advises governments on national programmes for the provision of basic sanitary services. The activities are directed to protection of the quality of air, water and food; health conditions of work; radiation protection and early identification of new hazards originating from new technological developments. A number of programmes have been developed such as the "WHO Environmental Health Criteria Programme" and "WHO Environmental Health Monitoring Programme" towards improving environmental health.

5. HEALTH STATISTICS
From its earliest days in 1947, WHO has been concerned with the dissemination of a wide variety of morbidity and mortality statistics relating to health problems. The data is published in the (a) Weekly Epidemiological Record (b) World Health Statistics Quarterly and (c) World Health Statistics Annual. Readers interested in current data may obtain it from the Chief Statistician, Dissemination of Statistical Information, WHO, Geneva. In order that statistics from different countries may be comparable, WHO publishes "International Classification of Diseases" which is updated every 10 years. The Ninth Revision of ICD came into effect from 1st January 1994. Assistance is also given to countries in the improvement of their medical records, and in the planning and operating national health information systems.

6. BIOMEDICAL RESEARCH
The WHO does not itself do research, but stimulates and coordinates research work. It has established a world-wide network of WHO collaborating centres, besides awarding grants to research workers and research institutions for promoting research. There are Regional Advisory Committees on health research which define regional health research priorities and a Global Advisory Committee, which in close collaboration with the regional committee deals with policy issues of global import. Six tropical diseases (malaria, schistosomiasis, trypanosomiasis, filariasis, leishmaniasis and leprosy) are the target of the WHO Special Programme for Research and Training in Tropical Diseases to develop new tools, strengthen research institutions and training workers in the countries afflicted.
7. HEALTH LITERATURE AND INFORMATION
WHO acts as a clearing house for information on health problems. Its publications comprise hundreds of titles on a wide variety of health subjects. The WHO library is one of the satellite centres of the Medical Literature Analysis and Retrieval System (MEDLARS) of the U.S. National Library of Medicine. MEDLARS is fully computerised indexing system covering the whole of medicine on an international basis. The WHO has also a public information service both at headquarters and each of the six regional offices.

8. COOPERATION WITH OTHER ORGANIZATIONS
WHO collaborates with the UN and with the other specialized agencies, and maintains various degrees of working relationships. Besides, WHO has also established relations with a number of international governmental organizations.

Structure
The WHO consists of three principal organs: the World Health Assembly, the Executive Board and the Secretariat.

(a) THE WORLD HEALTH ASSEMBLY: This is the "Health Parliament" of Nations and the supreme governing body of the organization. It meets annually, usually in May, and generally at the headquarters in Geneva, but from time to time in other countries. The Assembly is composed of delegates representing Member States, each of which has one vote. The main functions of the Health Assembly are:
(i) to determine international health policy and programmes;
(ii) to review the work of the past year; and
(iii) to approve the budget needed for the following year and to elect Member States to designate a person to serve for three years on the Executive Board, and to replace the retiring members. The Health Assembly also appoints the Director General on the nomination of the Executive Board. It is now the practice to organize on the occasion of each Health Assembly, "technical discussions" on some subjects of world interest.

(b) THE EXECUTIVE BOARD: The Board had originally 18 members, each designated by a Member State. Subsequently, the number was raised to 24 and 30. The Health Assembly (1976) increased the membership from 30 to 31, providing that no fewer than three are to be elected from each of the WHO regions (11). The board now has 34 members. The members of the Board are to be "technically qualified in the field of health"; they are designated by, but do not represent their governments. One-third of the membership is renewed every year. The Executive Board meets at least twice a year, generally in January and shortly after the meeting of the World Health Assembly in May. The main work of the Board is to give effect to the decisions and policies of the Assembly. The Board also has power to take action itself in an emergency, such as epidemics, earthquakes and floods where immediate action is needed.

(c) THE SECRETARIAT: The secretariat is headed by the Director General who is the chief technical and administrative officer of the Organization. The primary function of the WHO secretariat is to provide Member States with technical and managerial support for their national health development programmes. While in 1948, WHO staff counted 250 persons, the Organization in 1985 counted 4475 international public servants. The secretariat, by 2010, is staffed by about 8000 health and other experts and support staff. At WHO headquarters in Geneva, there are 5 Assistant Director Generals each of whom is responsible for the work of such divisions as may from time to time be assigned to him by the Director General. On 31st December, 1985, the WHO Secretariat comprised of the following divisions:

1. Division of epidemiological surveillance and health situation and trend assessment.
2. Division of communicable diseases.
3. Division of vector biology and control.
4. Division of environmental health.
5. Division of public information and education for health.
6. Division of mental health.
7. Division of diagnostic, therapeutic and rehabilitative technology.
8. Division of strengthening of health services.
9. Division of family health.
10. Division of non-communicable diseases.
11. Division of health manpower development.
12. Division of information systems support.
13. Division of personnel and general services.

Regions
In order to meet the special health needs of different areas, WHO has established six regional organizations. (Table 1).

<table>

</table>

The regional organizations are an integral part of the WHO and have under the constitution an important part in implementing the policies and programmes of the WHO. The regional office is headed by the Regional Director, who is assisted by technical and administrative officers, and members of the secretariat. There is a regional committee composed of representatives of the Member States in the region. Regional Committees meet once a year to review health work in the region and plan its continuation and development. Regional plans are amalgamated into overall plans for the Organization by the Director General at WHO's headquarters in Geneva.

The South East Asia Region
The headquarters of the South East Asia Regional Office (SEARO) is in New Delhi, the official address being World Health House, Indraprastha Estate, New Delhi. The region has now 11 members (Table 2).

The WHO activities in South East Asia Region cover a wide range of health services including eradication, tuberculosis control, control of other communicable diseases, health laboratory services and production of vaccines, health statistics, public health administration and rural health services, maternal and child health, nursing, environmental health and water supply, health education, nutrition, mental health, dental health, medical rehabilitation, quality control of drugs and medical education.

OTHER UNITED NATIONS AGENCIES
UNICEF

UNICEF (United Nations International Children's Emergency Fund) is one of the specialized agencies of the United Nations. It was established in 1946 by the United Nations General Assembly to deal with rehabilitation of children in war ravaged countries. In 1953, when the emergency functions were over, the General Assembly gave it a new name "U.N. Children's Fund" but retained the initials, UNICEF. UNICEF's regional office is in New Delhi; the region is known as the South Central Asia Region which covers Afghanistan, Sri Lanka, India, the Maldives, Mongolia and Nepal. UNICEF is governed by a thirty-six nation Executive Board as in 2010. The headquarters of the UNICEF is at United Nations, New York.

UNICEF works in close collaboration with WHO, and the other specialized agencies of the United Nations like UNDP, FAO and UNESCO. In the early years, UNICEF and WHO worked together on urgent problems such as malaria, tuberculosis and venereal diseases. Later, its assistance to countries covered such fields as maternal and child health, nutrition, environmental sanitation (especially the provision of water supplies to rural communities), health centres and health education and programmes which would directly or indirectly, benefit child health.

More recently, the tendency has been for UNICEF to turn away from campaigns for the eradication of specific diseases unless they are of direct benefit to mothers and children. Greater attention is being given to the concept of the "whole child" meaning that assistance should henceforward be geared not only to health and nutrition, as before, which are co immediate benefit to children, but also to their long-term personal development and to the development of the countries in which they live. This approach is also known as 'country health programming' in which UNICEF is currently interested as to meet the needs of children as an integral part of the country's development effort.

Content of services (12)
(a) Child health: UNICEF has provided substantial aid for the production of vaccines and sera in many countries. UNICEF has supported India's BCG vaccination programme from its inception. It has also assisted in the erection of a penicillin plant, near Pune; donated a DDT plant; two plants for the manufacture of triple vaccine and iodized salt. UNICEF has also assisted environmental sanitation programmes emphasizing safe and sufficient water for drinking and household use in rural areas. The purpose is not only to reduce child illness and death, but to improve the quality of life in the villages. Currently, UNICEF is focusing attention on providing primary health care to mothers and children. Emphasis is placed on immunization; infant and young child care; family planning aspects of family health; safe water and adequate sanitation. The services contemplated are intended to be so organized that the local community can participate in planning personnel and material support. The services will be delivered economically at the village level through resident volunteers or part-time primary health workers selected for the purpose with the agreement of the local community.
(b) Child nutrition: UNICEF gives high priority to improving child nutrition. Its aid for child nutrition, which first took the form of supplementing child diet, began to expand in mid-1950s with the development of low-cost protein-rich food mixtures. In collaboration with FAO, UNICEF also began aiding "applied nutrition" programmes through such channels as community development, agricultural extension, schools and health services so as to stimulate and help the rural population to grow and eat the foods it required for better child nutrition. The UNICEF has supplied equipment for modern dairy plants in various parts of India viz., Maharashtra, Gujarat, Karnataka, Uttar Pradesh, West Bengal, Andhra Pradesh. Special aid is also given for intervention against nutritional deficiency diseases, viz. provision of large doses of vitamin A in areas where xerophthalmia is prevalent; enrichment of salt with iodine in areas of endemic goitre; provision of iron and folic supplements to combat anemia and enrichment of foods. More recently, FAO, UNICEF and WHO have been encouraging the development of national food and nutrition policies that make provision for child nutrition.
(c) Family and child welfare: The purpose is to improve the care of children, both within and outside their homes through such means as parent education, day-care centres, child welfare and youth agencies and women's clubs. These services are carried out not as separate projects but as part of health, nutrition and education or home economics extension programmes.
(d) Education – formal and non-formal: In collaboration with UNESCO, UNICEF is assisting India in the expansion and improvement of teaching science in India. Science laboratories' equipment, workshop tools, library books, audiovisual aids are being made available to educational institutions. Emphasis is placed on the kind of schooling relevant to the environment and future life of the children.

Currently, UNICEF is promoting a campaign known as GORI campaign to encourage 4 strategies for a "child health revolution"
- G for growth charts to better monitor child development
- O for oral rehydration to treat all mild and moderate dehydration
- 3 for breast feeding, and
- 1 for immunization against measles, diphtheria, polio, pertussis, tetanus and tuberculosis.

Since 1976, UNICEF has been participating in Urban Basic Services (UBS). The aim of the UBS projects is to upgrade basic services (e.g., health, nutrition, water supply, sanitation and education) – especially for children and women – in selected cities and towns. The overall objective is to improve the degree and quality of survival and development of children in urban poor families.

In short, UNICEF activities cover programs assisting in child survival, protection and development: interventions like immunization, improved infant feeding practices; child growth monitoring, household-based diarrhoea management, drinking water, environmental sanitation, birth spacing, education of girls and income- generating activities for women.

As full partners in primary health care, UNICEF and WHO have been developing joint strategies in support of its implementation at country level.

UNDP
The United Nations Development Programme (UNDP) was established in 1966. It is the main source of funds for technical assistance. The member countries – rich and poor – of the United Nations meet annually and pledge contributions to the UNDP.

The basic objective of the UNDP is to help poorer nations develop their human and natural resources more fully. The UNDP projects cover virtually every economic and social sector – agriculture, industry, education and science, health, social welfare, etc.

UN Fund for Population Activities
The United Nations Fund for Population Activities (UNFPA) has been providing assistance to India since 1974. In addition to funding national level schemes, Area Projects for intensive development of health and family welfare infrastructure and improvement in the availability of services in the rural areas have been under implementation in eleven districts of Bihar and 4 districts of Rajasthan.

The UNFPA inputs are designed to develop national capability for the manufacture of contraceptives, to develop population education programs, to undertake organized sector projects, to strengthen program management as well as to improve output of grass-root level health workers and introduction of innovative approaches to family planning and MCH care (16).

FAO
The Food and Agriculture Organization (FAO) was formed in 1945 with headquarters in Rome. It was the first United Nations Organization specialized agency created to look after several areas of world cooperation. The chief aims of FAO are: (1) to help nations raise living standards (2) to improve nutrition of the people of all countries (3) to increase the efficiency of farming, forestry and fisheries (4) to better the condition of rural people and, through all these means, to widen the opportunity of all people for productive work. FAO’s prime concern is the increased production of food to keep pace with the ever-growing world population. The most important aspect of FAO’s work is towards ensuring that the food is consumed by the people who need it, in sufficient quantities and in right proportions, to develop and maintain a better state of nutrition throughout the world (13).

In this context, the FAO has organized a world Freedom from Hunger Campaign (FFHC) in 1960. The main object of the Campaign is to combat malnutrition and to disseminate information and education. The FAO is also collaborating with other international agencies in the Applied Nutrition Programmes. The Joint WHO/FAO expert committee has established many cooperative activities – nutritional surveys, training courses, seminars and the coordination of research programmes on beri-beri and other ailments (4).

ILO
Soon after the First World War, it was recognized that problems of industry, like disease, know no frontiers. In 1919, the International Labour Organization (I.L.O.) was established and is an affiliate of the League of Nations to improve the working and living conditions of the working population all over the world. The purposes of ILO are: (1) to contribute to the establishment of lasting peace by promoting social justice (2) to improve, through international action, labour conditions, and living standards and (3) to promote economic and social stability. The International Labour Code is a collection of international minimum standards related to health, welfare, living and working conditions of workers all over the world. The ILO also provides assistance to organizations interested in the betterment of living and employment standards. There is a close collaboration between ILO and WHO in the field of health and labour. The headquarters of ILO is in Geneva, Switzerland.

World Bank
World Bank is a specialized agency of the United Nations. It was established with the purpose of helping less developed countries raise their living standards. The power of the Bank are vested in a Board of Governors. The Bank gives loans for projects that will lead to economic growth (e.g., India’s Population Projects). The projects are usually concerned with electric power, roads, railways, agriculture, water supply, education, family planning, etc. Health and environmental components have been added to many projects. Cooperative programmes exist between WHO and the Bank, e.g., projects for water supply, World Food Programme,Population, Cooperation. The control of onchocerciasis programme in West Africa (14).

Health Work of Bilateral Agencies

USAID
The US Government presently extends aid to India through three agencies: (1) United States Agency for International Development (USAID); (2) The Public Law 480 (Food for Peace) Program and (3) The US Export-Import Bank. The USAID was created in 1961; it is in charge of activities previously administered by the Technical Cooperation Mission (TCM). A USAID mission functions in New Delhi. Both grants and loans are extended by the Agency.

The US has been assisting in a number of projects designed to improve the health of India’s people. These are: (1) malaria eradication (2) medical education (3) nursing education (4) health education (5) water supply and sanitation (6) control of communicable diseases (7) nutrition (8) and family planning (15) The recent trend in assistance
from the USA is increasingly in the support of agricultural and family planning programmes, with some reduction in aid in the general public health field (5).

THE COLOMBO PLAN
At a meeting of the Commonwealth Foreign Ministers at Colombo in January 1956, a programme was drawn up for cooperative economic development in South and South-East Asia. Membership comprises 20 developing countries within the region and 6 non-regional members – Australia, Canada, Japan, New Zealand, UK and USA. The bulk of Colombo Plan assistance goes into industrial and agricultural development, but some support has also been given to health promotion, mostly through fellowships. The All India Institute of Medical Sciences at New Delhi was established with financial assistance from New Zealand. The Plan provides for visits to countries by experts who can offer advice on local problems and train the local people. The contribution of Canada in supplying Cobalt Therapy Units to medical institutions in India was an important item of aid under the Colombo plan (5). Colombo plan seeks to improve living standards of the people of the area by reviewing developmental plans and coordinating development assistance.

SIDA
The Swedish International Development Agency is assisting the National Tuberculosis Control Programme since 1979. The SIDA assistance is usually spent on procurement of supplies like X-ray unit, microscopes and anti-tuberculosis drugs. SIDA authorities are also supporting the Short Course Chemotherapy Drug Regimens under pilot study, which were introduced in 15 districts of the country, during 1965-84, and pilot phase-I of the Revised strategy of NTP in 5 sites namely Delhi, Bangalore, Mumbai, Kolkata and Mehsana (Gujarat) since 1993.

DANIDA
The Government of Denmark is providing assistance for the development of services under National Blindness Control Programme since 1978.

NON-GOVERNMENTAL AND OTHER AGENCIES

Rockefeller Foundation
The Rockefeller Foundation is a philanthropic organization chartered in 1913 and endowed by Mr. John D. Rockefeller. Its purpose is to promote the well-being of mankind throughout the world. In its early years, the Foundation was active chiefly in public health and medical education. Subsequently, its interest was expanded to include the advancement of life sciences, the social sciences, the humanities and the agricultural sciences (17).

The work of the Rockefeller Foundation in India began in 1920 with a scheme for the control of hookworm disease in the then Madras Presidency. Since then, the Foundation has been associated with several medical and public health programmes in India. The establishment of the All India Institute of Hygiene and Public Health at Kolkata was in a large measure due to the cooperation of the Rockefeller Foundation. The Foundation’s programme included the training of competent teachers and research workers; training abroad of candidates from India through fellowships and travel grants; the sponsoring of visits of a large number of medical specialists from the USA; providing grants-in-aid to selected institutions; development of medical college libraries; population studies; assistance to research projects and institutions (e.g., National Institute of Virology at Pune and more recently the setting up of a field demonstration area (Ballabgarh) in connection with a department of preventive and social medicine, as well as to the All India Institute of Medical Sciences at Rishikesh.

Ford Foundation
Whereas the Rockefeller Foundation earlier concentrated most of its assistance on universities and post-graduate institutions, on professional education and in research, the Ford Foundation has been active in the development of rural health services and family planning (5). The Ford Foundation has helped India in the following projects:

1. Orientation training centres: The orientation training centres at Sirug, Poonamallee and Najaipur were set up with help from the Ford Foundation. The centres provide training courses in public health for medical and paramedical personnel from all over India. (2) Research-action projects: These projects were aimed at solving some of the basic problems in environmental sanitation, e.g., designing and construction of hand-flushed acceptable sanitary latrines in rural areas (3) Pilot project in rural health services, Gandhigram (Tamil Nadu): Among a rural population of 100,000 people, an attempt was made to develop and operate a coordinated type of health service which would provide a useful model for health administrators in the country. (4) Establishment of NAIHE: In the last few years, the Ford Foundation has supported the establishment of the National Institute of Health Administration and Education at Delhi. The Institute provides a senior staff-college type training for health administrators. (5) Calcutta water supply and drainage scheme: The Foundation has helped in the preparation of a master plan for water supply, sewerage and drainage for the city of Calcutta in collaboration with other international agencies. (6) Family planning programme: The Foundation is supporting research in reproductive biology and in the family planning fellowship programmes.

CARE
CARE (Cooperative for Assistance and Relief Everywhere) was founded in North America in the wake of the Second World War in the year 1945. It is one of the world’s largest independent, non-profit, non-sectarian international relief and development organization. CARE provides emergency aid and long term development assistance.

CARE began its operation in India in 1950. Till the end of 1960s, the primary objective of CARE – India was to provide food for children in the age group of 6-11 years. From mid 1980s, CARE-India focused its food support in the ICDS programme and in development of programmes in the areas of health and income supplementation. It is helping in the following projects: Integrated Nutrition and Health Project; Better Health and Nutrition Project; Anemia Control Project; Improving Women’s Health Project; Improved Health Care for Adolescent Girls Project; Child Survival Project; Improving Women’s Reproductive Health and Family Spacing Project; Konian Integrated Development Project etc.
CARE—India works in partnership with the Government of India, State Governments, NGOs etc. Currently it has projects in Andhra Pradesh, Bihar, Madhya Pradesh,Maharashtra, Orissa, Rajasthan, Uttar Pradesh and West Bengal.

International Red Cross

The Red Cross is a 100-year-old non-official international humanitarian organization devoted to the service of mankind in peace and war. It was founded by Henry Dunant, a young Swiss businessman, who, when travelling through North Italy in 1859 happened to be on the scene of one of the most savage battles of history, the battle of Solferino. Appalled by the neglect of thousands of the wounded and dying soldiers, Dunant recruited volunteers from nearby villages to help relieve their suffering. Later, in his book "Un Souvenir de Solferine" and in countless interviews with eminent persons, throughout Europe, Dunant urged that voluntary national societies be founded "which in time of war would render aid to the wounded without distinction of nationality". He proposed further that these societies should have a protective emblem and trained workers and their services to the wounded should be protected by international treaty.

Dunant’s plea met with success. The First Geneva Convention took place in 1864 and a treaty was signed for the relief of the wounded and the sick of the armies in the field. This came into being the International Committee of the Red Cross (ICRC), an independent, neutral institution, the founder organization of the Red Cross. It has since grown into a mighty mission with branches all over the world symbolising the spirit of compassion and universal brotherhood. In 1919, the League of the Red Cross Society was created with headquarters in Geneva to coordinate the work of the national societies, which now number more than 100.

Role of Red Cross

In the beginning, the role of the Red Cross, as conceived by Dunant, was largely confined to humanitarian service on behalf of the victims of war. Soon thereafter, it was realized that natural disasters too bring in their wake great human suffering and that on such occasions there is equally great need for help among nations "as good neighbours". Later on the work of the Red Cross was extended to other programmes which would prevent human suffering. These comprise service to armed forces, service to war veterans, disaster service, first aid and nursing, health education and maternity and child welfare services.

Indian Red Cross

The Red Cross Society of India was established by an Act of the Indian Legislature in 1920 with the three objectives of the improvement of health, prevention of disease and mitigation of suffering. In peacetime the Society provides services to hospitals with such amenities as newspapers, periodicals, musical instruments and other comfort goods. The Red Cross Home at Bangalore for disabled ex-servicemen is one of the pioneer institutions of its kind in Asia. Disaster services comprise distribution of milk, medicines, Vitamin tablets, cordwinder oil and hundred other items to the famine stricken people and to those who have been hit by the floods. In the development of maternity and child welfare services, the Society has done pioneering work and has functioned as an auxiliary of the country’s health services.

The JUNIOR RED CROSS is one of the most active sections of the Society. It gives an opportunity to lakhs of boys and girls all over India to be associated with activities like the village uplift, first aid, antipelandic work and building up of an international fraternity of youth, thus promoting international friendship, understanding and cooperation.

There are numerous other non-governmental organizations (NGO’s). Some of these are: Oxfam, Save-the-Children Fund, International Planned Parenthood Federation, The Population Council, Voluntary Health Association of India, All India Women’s Conference, India Medical Association, Trained Nurses Association of India, International Agency for the Prevention of Blindness, World Federation of the Deaf, International Leprosy Association, World Federation of Medical Education, International Union Against Cancer, and so on. Non-governmental organisations constitute a valuable resource in promoting health care.
